

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. MOZAMBIQUE

MOZAMBIQUE, or **MOSAMBIQUE**, a name applied to a large extent of the seaboard of E. Africa, belonging to Portugal; pop. estimated at 300,000, including about 22,000 slaves. It is bounded E. by the Mozambique channel, N. by Cape Delgado, lat. $10^{\circ} 38' S.$, and S. by Delagoa bay, lat. $26^{\circ} S.$; on the W. it cannot be said to have any definite interior boundary. The coast is characterized by the two prominent headlands of Cape Corrientes in the S. and Cape Delgado in the N.; and also by several large bays, the chief of which are Delagoa, Mocambo, and Pamba. Between Delagoa bay and Cape Corrientes, and from Mozambique city to Cape Delgado, the shores are high and precipitous; while reefs and numerous islands lie off the land nearly throughout its entire length. Many large streams discharge themselves here; the principal is the Zambesi, the largest river of E. Africa, which debouches by several mouths at the middle point of the Mozambique coast. Dr. Livingstone is now (1860) engaged in exploring the Zambesi. Considerable tracts of the country are cultivated and yield abundant crops of rice. The forests supply wood of great beauty and value. The rivers abound with hippopotami, which yield fine ivory. Gold is obtained in considerable quantities by washing the sands, and copper ore is said to be found in several places. The vast plains of the interior abound in elephants, lions, and other wild animals, from which ivory and valuable skins are obtained. The Portuguese, however, have so neglected their possessions that the trade and government are now in a very feeble condition; and at some stations the latter is said to be more in the hands of influential native chiefs than in those of the Portuguese governor. The military force, 1,096 men, consists of a very inferior class of soldiers. The coast for administrative purposes is divided into 6 sub-districts, of which Mozambique is the head. A governor-general and secretary, appointed by the crown, administer the government, assisted by a *junta*, which is composed of a president, treasurer, and 12 members. The established religion is Roman Catholic, and is superintended by a prelate, a prior, and 12 parochial priests. Education, which, like religion, is here at a very

low ebb, is dispensed by 16 teachers in all, 4 of whom are females, and most of them reside in the capital. The Portuguese settlements, beginning from the N., are San João, Mozambique, Quilimane, Sena, Tete, Sofala, Inhamban, and Lorenzo Marques; all of which are more or less decayed.—This coast was known to the Arabs centuries before its discovery by Europeans. When first visited by the Portuguese in 1497, the whole coast was in possession of the Arabs; but the fame of its gold mines and the convenience of its ports as resting places for the Indian trade, led them to attempt the expulsion of the original settlers. This was not difficult, and in 1508 they had obtained a footing in two places, and built a fort upon the island of Mozambique. The Portuguese made some attempts to penetrate the interior, but were not very successful; and latterly they have contented themselves with acting on the defensive, occupying the spots already mentioned on the coast and along the banks of the river Zambesi. In some places the natives are decidedly inimical to the Portuguese authority, which does not extend 10 consecutive miles in any direction. The slave trade is still actively carried on. In 1846 Governor Abreu de Madeira was removed from Quilimane for being concerned in it; his successor deserted his post, and escaped in a ship with a large cargo of slaves. In 1847 the governor-general, a distinguished officer, was suspended for malpractices; and the governor-general in 1857 was removed for carrying on the slave trade, decisive measures for the suppression of which were adopted by his successor, Col. d'Almeida.—**MOZAMBIQUE**, the capital of the above territory, is on a coral island near the mainland; pop. 8,522, including 7,000 slaves. The centre of the island is in lat. $16^{\circ} 3' S.$, long. $40^{\circ} 48' E.$ It is about $1\frac{1}{2}$ m. long, and $\frac{1}{2}$ m. broad, in the form of a crescent, with the hollow side toward the sea; and, with two other islets, it is situated near the mouth of a bay some 6 m. long and 5 broad, which furnishes a safe and excellent harbor. The ground on which the town stands is from 20 to 50 feet above the level of the water, and the position is strongly fortified. The governor's palace is an extensive stone building.

There are 2 churches and 8 small chapels, a hospital, prisons, tanks, and storehouses. The streets are very narrow, and the houses being all whitewashed, the glare and heat are very great, the mercury rising from 6° to 10° higher in the town than on the mainland. The inhabitants are a strange mixture of Indian, Arabian, and European, and their costumes are as various as their races. With the exception of the governor and his staff, the greater part of the European settlers are culprits who have been sentenced to banishment. A few years ago there were only 7 white women in the colony. Other classes are the descendants of the old Arab settlers, most of whom are sailors, the Banian traders from Hindostan, and negroes. The merchants of Mozambique in former days supplied nearly all the markets in that part of the world with slaves, beside sending some to the West India islands. The legitimate traffic of the place is principally carried on by Arab ships, which bring piece goods and eastern produce from India, and take back ivory, gold dust, and dollars. The climate is hot and unhealthy, especially in the months of September, October, and November. The natives on the mainland in the neighborhood are athletic and savage.

MOZAMBIQUE CHANNEL, the passage between the E. coast of Africa and the island of Madagascar, lat. 12° to 25° S. At its S. entrance it is 550 m. wide, at its N. nearly 600, and in the centre about 250. Its length from N. E. to S. W. is about 1,060 m. The Comoro islands lie at its N. entrance.

MOZART, JOHANN GEORG LEOPOLD, a German musician, born in Augsburg, Nov. 14, 1719, died May 28, 1787. He was gifted with good musical talents, became early a singing boy in the church of the Holy Cross, and without neglecting other studies made himself thoroughly acquainted with music, theoretical and practical, astonishing his hearers while still a youth by his performance upon the organ at Munich, and at a later period laying the foundation for modern German violin playing. By teaching music he paid his way while studying law, which he had chosen for a profession, and which brought him early to Salzburg, partly to perfect his studies, partly in the hope of obtaining a place under the provincial government. In this he was disappointed, and was forced by poverty to accept a position as chamberlain in the service of Count Thurn, a prebendary of the cathedral. At the age of 24 Archbishop Sigismund appointed him chamber musician. A few years later he was advanced to the position of court composer and leader of the orchestra, and reached the dignity of vice-chapellmaster in 1762. In 1757 his works were already very numerous—for the church, the orchestra, solo instruments, and indeed in all departments. "His style," says a contemporary, "is somewhat old-fashioned, but solid and full of contrapuntal insight. His church music is of more value than that for the chamber." A work which at once gave him a name

throughout Germany was his "Violin School," which appeared in 1756. It is remarkable not only as the first of its kind, but for the earnestness with which it inculcates the idea that mere execution is not at all that which is demanded of a pupil—that this is but a means to the true artistic end. In 1747 Leopold Mozart married Anna Maria Pertlin, and had by her 7 children, of whom but two survived, a daughter and a son. The son was the great Mozart, and from the time that his extraordinary genius was discovered, the father made its culture and development the business of his life, and almost disappears from musical history except in connection with his son. The daughter, Maria Anna Walburga Ignatia (born 1761, died 1829), appeared as pianist in the musical tours made by her family from 1762 to 1767, and afterward devoted herself to teaching. In 1784 she married Johann Baptist, baron von Berchthold.

MOZART, JOHANNES CHRYSOSTOMUS WOLFGANG AMADEUS, a German composer, son of the preceding, born in Salzburg, Jan. 27, 1756, died Dec. 5, 1791. In his 3d year he attracted the notice of his father by the delight he found in striking chords upon the harpsichord, and by the ease with which he learned pleasing passages in the music lessons of his sister. In his 4th year his father began to teach him short pieces for the harpsichord. In his 5th year he composed little melodies with simple but perfectly correct harmonies, which his father wrote out, and specimens of which may be seen in the biographies by Holmes and Nissen. He was in an eminent degree a serious, tender, affectionate child, so obedient as never to have received the slightest corporal punishment from father or mother. His intellect was exceedingly quick, and, though music was all in all to him, he became at once interested in whatever studies were given to him, showing great talents for the study of languages and mathematics. During the journeys which Leopold Mozart made for the purpose of producing his children at the principal courts of Europe, the child had enlarged opportunities of hearing the best music in all styles and departments, and of making the acquaintance of the greatest performers of that age. The first of these artistic tours was to Munich, in Jan. 1762, when Wolfgang was just 6 years old. The two children played before the elector, and excited the deepest astonishment and wonder. In the autumn of the same year they visited Vienna, stopping on the way in Passau to play before the bishop, who rewarded them with one ducat; in Linz to give a concert; and a few hours at the Franciscan convent of Ips, where Wolfgang, getting access to the organ, played so finely that the monks and several guests left their dining table to listen. The fame of the little musicians had preceded them to Vienna, and they found immediate access to the highest circles, the only circles in fact which then cultivated music, that art being the luxury of the nobles and the rich. Before the father was able to apply for an audience at court, he was ordered to appear with his

children at Schönbrunn. The emperor Francis took great delight in the "little magician," as he called Wolfgang, causing him to play with one finger, with a cloth over the keys, and the like. The favor of the court made them the fashion, and the father was as much gratified by pecuniary success as by the unbounded applause which his children gained. In October the boy was seized with scarlet fever, which interrupted their good fortune. They paid a visit to Presburg, and reached home in Jan. 1768. Wolfgang had acquired no small skill also upon the violin, and on his return played at sight the 2d violin part in 6 trios, which a pupil of his father had written during his master's absence. Schachtner relates that calling at the house one day, he found Wolfgang playing his little instrument. Suddenly, after thinking a moment, he exclaimed: "Herr Schachtner, your violin is tuned half a quarter of a note lower than mine here, if you have left it as it was when I last played it." At the request of the father Schachtner's violin was brought and found to be as Wolfgang had said. This extraordinary memory for pitch was afterward one of the child's powers publicly exhibited. In the summer of 1768 another tour was undertaken, extending to Paris and London. The boy, now 7 years of age, excited more wonder with old musicians by his organ playing than by his performances upon the harpsichord and violin. In Heidelberg this was commemorated by an inscription placed upon the organ. At this season most of the princes before whom the children played were in their summer residences, and the correspondence of the father gives details of visits to several. In Nymphenburg Wolfgang played a violin concerto before the elector of Bavaria. Thus playing in private before princes, and giving concerts in the cities, they at length came to Frankfurt-on-the-Main. An extract from the advertisement of a concert in this city, Aug. 30, will give an idea of the programmes usually performed by the children: "The girl, now in her 12th, and the boy, in his 8th year, will not only play concertos upon the harpsichord—the girl indeed the most difficult pieces of the greatest masters—but the boy will also perform a concerto upon a violin, accompany in symphonies upon the harpsichord, will cover the keys with a cloth and play as well as if they were in sight, and will also designate any note or chord struck at a distance, whether upon a harpsichord or any other musical instrument, or upon bells, glasses, musical clocks, &c. Finally, he will extemporize, not only upon the harpsichord, but also upon the organ, so long as any one desires, in all, even the most difficult keys that can be proposed, and thus prove that he understands the organ, which is totally different from the harpsichord in its treatment." By way of Coblenz, Aix la Chapelle, and Brussels, in all which places they played with the usual applause, they came to Paris in November. Their reception at the French court was all that the father could

wish. The daughter astonished by the precision and elegance with which she performed the music of Schobert and Eekart, then the most difficult writers for keyed instruments, as well as most in vogue; the son, not more by his performances upon harpsichord, organ, and violin, than by his musical knowledge. He accompanied Italian and French airs at sight, transposing them instantly when required to do so—a task doubly difficult in those days, when the accompanist had to read the full score or depend upon a figured bass. Grimm records that upon one occasion Wolfgang was put to the test by being called upon to accompany a lady in an aria which he had never heard, and of which the music was not given him. He was thus forced to guess at the proper harmonies from the current of the melody. The first time there were occasionally false accords; the second time he played the melody with a correct accompaniment. The air was then repeated 10 times, and on each repetition the child changed the form and character of the harpsichord part. At this time Wolfgang's first work was published, consisting of 4 sonatas for harpsichord and violin. In April, 1764, the family went to London, where they remained until July, 1765. Their reception here, by king, court, and nobility, if possible surpassed in enthusiasm what they had experienced in Paris. The Hon. Daines Barrington made Wolfgang the subject of a communication published in the philosophical society's "Transactions;" the queen accepted the dedication of 6 sonatas for pianoforte and violin from his pen; the public crowded the concerts which they gave, and in which the boy appeared in a new character, that of composer of symphonies for the orchestra. They returned through Holland up the Rhine, and through Switzerland, to Salzburg, where they arrived in Nov. 1766. Leopold now settled again quietly in Salzburg, and put both children to a systematic and thorough study both of instrumental execution and the theory of music. Wolfgang in particular was set to work upon Emanuel Bach, Hasse, Handel, and the old Italian masters, whom he studied with unflagging zeal. A German passion cantata and a Latin *comedia*, "Apollo and Hyacinth," the latter performed by the students in the Salzburg university, attest his progress in contrapuntal study and composition in 1767. The approaching nuptials of one of Maria Theresa's daughters with Ferdinand, king of Naples, induced Leopold Mozart to visit Vienna again at the close of this year. It occurred to Joseph II. that an opera of the boy's composition would be interesting, and he expressed a wish for one to the manager of the court stage. An Italian opera buffa, *La finta semplice*, was selected, and Wolfgang was engaged to compose it on the usual terms, 100 ducats. The score was finished soon after Easter. It is still preserved, and is fully up to the standard of similar works of that period, even those from composers of established reputation. It never reached a per-

formance, in consequence of cabals and intrigues; nor could Joseph command it, since the theatres at that time were leased. Leopold Mozart struggled heroically for his own and his son's honor for some 6 months, but was forced finally to give way. Since the death of her husband, Maria Theresa had given up the opera and concerts, and could not aid the Mozarts in this matter; but she gave Wolfgang an opportunity to show himself as composer and music director, by ordering of him a mass for the dedication of the orphan house church, which he composed in the autumn, and conducted in presence of the empress and court, Dec. 7, 1768. In a private circle, too, Wolfgang proved his dramatic talent by the composition of an operetta, "Bastien and Bastienne." The result of the journey was little money and much credit; so much of the latter, that upon returning to Salzburg Archbishop Sigismund appointed the boy concert master. The year 1769 was again devoted to severe and solid study. Two masses bearing this date prove the pains taken by the father that his son should become a contrapuntist of the severest school, as the foundation for the future practice of free composition. In December of this year Wolfgang accompanied by his father set out for Italy, both for his improvement and for the recognition of his talents by the great Italian masters. Concerts were given in Innsbruck, Roveredo, Verona, and Mantua, Wolfgang appearing as singer, composer, and performer upon the harpsicord, organ, and violin. His extemporaneous compositions had with musicians the greatest weight, as in them nothing but originality of ideas and a thorough mastery of musical grammar, rhetoric, and logic (if we may so speak), could carry him through with success. The composition of several arias to words from Metastasio gave such proofs of his talent for vocal composition, as his symphonies and concertos for orchestral writing, that the composition of an opera for the next winter was offered him under very flattering auspices, and upon fair if not generous terms. In Lodi Wolfgang composed his first string quartet; and in Rome he took down Allegri's *Miserere* from hearing it in the Sistine chapel—a feat, however, by no means so great as has been represented. The pope gave the Mozarts an audience (July 8), and conferred upon the son the order of the golden spur—the same which gave Gluck and other composers the title of Ritter or chevalier. On their way again to Milan they spent several weeks in Bologna, where Wolfgang had the advantage of much intercourse with Padre Martini, and where he was made member of the philharmonic society (Oct. 9). Ten days later he was again in Milan, and busy upon his opera *Mitridate, re di Ponto*. In less than two months it was finished and rehearsed, and on Dec. 26 successfully given, the little composer presiding during the performance at the harpsichord. It ran 20 nights, and when he left Milan the

score remained behind, that the copyist might fill orders for 5 copies, one of which was for Lisbon. They visited Turin, Padua (where an oratorio was ordered from Wolfgang, probably the *Betulia liberata*), Vicenza, and Verona, with no abatement of their success, and reached home in March, 1771. The marriage of the archduke Ferdinand with a daughter of the prince of Modena was to be celebrated in the autumn at Milan with great splendor, and Maria Theresa had ordered for the occasion an opera by Hasse and a serenata by Mozart. In August, therefore, they again reached Milan, but it was already September before the text to the serenata—*Ascanio in Alba*, in two acts with ballet—was delivered. There were now hardly 6 weeks for the composition and rehearsal of the work. It was, however, ready at the time, and killed Hasse's opera completely. Just as they reached Salzburg again Archbishop Sigismund died. His successor, Hieronymus, Count Colloredo, has an undying name in the annals of art as a tyrant, who did all in his power to break the spirit, crush the hopes, and ruin the prospects of a youth, whose character was as lovely and conduct as spotless as his genius and acquirements in his art were beyond any known standard. For the festivities of his installation Mozart was ordered to compose Metastasio's opera, *Il sogno di Scipione*. It was a hasty composition, and bears more marks of being a mere occasional piece than any other from the composer's pen. In November he again reached Milan, bringing with him a part of the recitative of an opera which had been ordered, but changes in the text forced him to rewrite most of it. The singers were not yet there for whom he was to adapt the principal parts. It was already December, and only the recitative, choruses, and overture were finished. Yet on the 26th it was publicly given, and, in spite of a bad performance, was a success. It was repeated more than 20 times; but notwithstanding its success it was Mozart's last opera written for the stage in Italy—a fact which has but one solution, namely, that Hieronymus refused his concert master from that time onward, save in a single instance, leave of absence. In the autumn of 1774 came an order for a comic opera for Munich. Happily Hieronymus stood in such relations to the elector, that he could not refuse Mozart on this occasion the necessary leave of absence. The fine orchestra and excellent singers were a new spur to the young man, and this effort surpassed all his previous ones. The opera was *La finta giardiniera*, performed Jan. 13, 1775. A visit of Maria Theresa's youngest son, Maximilian, afterward elector of Cologne, to Salzburg, was the occasion of Mozart's last youthful operatic composition; it was Metastasio's *Il re pastore*. During the next two years Mozart must be pictured filling his position as concert master at a court where there is a constant demand upon him as performer and composer. He was the favorite of all classes, and had but one enemy who was

unfortunately the man upon whom he depended for subsistence. He was wretchedly paid for his services, and only by the utmost economy could the Mozart family avoid incurring debts. In those days little was to be gained by publishing music, and lessons were poorly paid. Another artistic tour was a necessity, and was determined upon. As a preparation for this, Mozart went again through a course of study in perfecting himself as a performer upon the organ, harpsichord, and violin. In the autumn of 1777 the father petitioned for leave of absence for himself and son. It was rudely refused. Wolfgang, now of age, immediately resigned his place as concert master. He was the first pianist, one of the first organists, and in the highest rank of violinists in Europe; and the author of more than 200 works, from the opera, grand mass, and symphony, down through all kinds and classes of compositions. He first went to Munich with his mother, but there was no vacancy for him to fill; and he then turned his steps to Mannheim, where, though he was kindly received, he could not obtain employment. He stayed here until March, 1778, partly in consequence of a passion for a beautiful young singer, Aloysia Weber. The mother and son now tried Paris, where they arrived March 23. The contest between the Gluckists and Piccinists was at its height, and they with the French composers filled the stage. Baron Grimm received the Mozarts with great kindness; but he belonged to the Italian party. He procured Mozart a few pupils, who paid him well, and they were his main dependence during his stay in Paris. Le Gros, the conductor of the *concerts spirituels*, and others, were very ready to use the young composer's talents for their own benefit, until he was forced to refuse any application for new music not accompanied by the offer of a reasonable compensation. The spring passed away, and the prospect began to improve. Le Gros ordered a symphony, which was given with the greatest applause. Just at this moment Madame Mozart died (July 3). Her death, a terrible blow to Mozart, who was one of the most affectionate of sons, was followed by peremptory orders from his father to return to Salzburg. Leopold Mozart, so long as he lived, seems never to have conceived that his son could go alone, or be freed from his leading strings; and at this juncture in particular Paris was in his eyes a place of the greatest danger for the young man, both morally and pecuniarily. Grimm, after the death of the mother, took the son into his own house; but he felt a responsibility for his welfare from which he was anxious to be free, and urged Wolfgang to return home. The archbishop felt the need of his former concert master, and had at last made a definite proposition for his return. Fortune was evidently turning in Mozart's favor at Paris, but, hard as it was, he felt it to be his duty to obey his bereaved father, and on Sept. 26 he bade Paris farewell. The time spent there had been of the greatest value to him.

He had had opportunity to make himself perfectly familiar with many of the principal works of the three great schools of opera, Gluck's, the Italian, and the purely French. His acquaintance with men of his own and other professions had been widely extended; the coming of Christian Bach from London and his friendship for Mozart opened a prospect for the future also in the English capital; the place of organist at Versailles, almost a sinecure, had been proposed for his acceptance. It was with a heavy heart that he journeyed on—lingering at Nancy and Strasbourg, turning aside to visit Mannheim again, delaying at Munich, where he met the Weber family and found that Aloysia's love for him had grown cold—so that it was already Jan. 1779, before he reached Salzburg. Mozart, as the court calendar shows, was now "concert master and court and cathedral organist;" the salary was small, but, added to that of the father and what was earned by them and the sister by teaching, sufficed to enable the family to live in comfort, and gradually to pay the debts which the recent journey to Paris and the death of the mother had caused them to incur. The most favorable point in the new contract was, that leave of absence should be granted at reasonable intervals when necessary for the production of new works in other cities. So passed another period of nearly two years, Mozart being continually called upon for new music for church and chamber, and supplying the demand with a succession of works ever new and ever more beautiful, but which we have no space to enumerate. Of dramatic music during this period he produced only the choruses and *entr'actes* to the play of "Thamos, King of Egypt," for Emanuel Schikaneder, who came to Salzburg with a troupe of actors, and an operetta, which, though not completed, has been published with the title of *Zaide*. In Munich he was not forgotten, and in 1780 received the order for the opera seria for the ensuing carnival. This was *Idomeneo*, which he partially composed at home and finished at Munich. It was produced Jan. 29, 1781. Five years had now elapsed since his last work for the operatic stage. That had been in the old, formal Italian style. *Idomeneo* from the character of the text was necessarily to some extent of the same school, but bears everywhere marks of the composer's studies and observations at Paris, and exhibits throughout proofs of a genius fast becoming independent of all traditional forms. It still keeps the stage, and is the oldest, except some of Gluck's works, now to be heard on any stage. It was received with applause amounting to enthusiasm. The composer lingered in Munich through the winter, producing masses in the church and works in all forms in the concert room. Charles Theodore had now succeeded to the electorate, and had removed from Mannheim to Munich, bringing with him all his old enthusiasm for music. Mozart had hopes of obtaining a permanent appointment at this court, when he received a peremptory order

from Archbishop Hieronymus to meet him at once in Vienna. Mozart and the two other musicians in the archbishop's train were not placed on a par with the domestics; they dined at a separate table with the two chamberlains and the three head cooks, the musicians sitting above the cooks. The archbishop exhibited his concert master both as performer and composer, but took special care that he should have no opportunity of playing where his performance could add to his miserable income; and only through the persistency of men to whom Hieronymus dared not say no, had Mozart opportunity to play in the grand annual charitable concert. The impression made by him on this occasion was a new thing in the annals of music, even in Vienna. This success is the only known reason why early in May Mozart was suddenly ordered to return to Salzburg. An accident caused him to delay a few days; when ready to depart he called upon his master to excuse himself and take leave, and was received with a torrent of abuse. For 6 weeks the young man, remembering the position of his father, had borne the indignities to which he was subjected in silence, but this was too much. "Finally, my blood," wrote he, "was too much excited, and I said: 'Your reverend and princely grace is then dissatisfied with me?' 'What! do you threaten me? You scoundrel—oh, you scoundrel!—with such a miserable boy I will have nothing to do.' So at last I said: 'Nor I with you any more.'" The next day Mozart sent in his demand for a dismissal from the archbishop's service. Four weeks passed, and no answer. The archbishop supposed the storm would pass over, but on June 8 Mozart handed in another petition. He was received by Count Arco, "master of the kitchen," who loaded him with vile epithets, and finally kicked him out of the room. Nothing but the stern remonstrances of the father prevented the son, diminutive as he was, from publicly calling Arco to account. No reason has ever been suggested for the hatred of the archbishop, except that both Mozarts were men of independence who disdained to play the part of flatterers. Mozart, now 25 years old, was cast upon his own resources, a position for which unhappily his education had but ill fitted him. He gave lessons and concerts, published music by subscription, and had no serious difficulty in obtaining the means of subsistence. At all events he was independent, was universally honored, respected, and liked, save by his opponents of the Italian school, Salieri at the head, and was happier than he had been for years. For some months he resided in the family of his old friends the Webers, now established in Vienna, where Aloysia, who had married Lange the actor, was engaged as a singer. The emperor Joseph was busied at this time with his project of establishing a German opera. He was always friendly to Mozart, and ordered a composition from his pen for the new company. This was the opera "Belmont and Constanza." Mozart received the text in July,

1780, and soon had the music finished. But he had to encounter all the opposition which the singers and orchestra could make, urged on by the Italian party; and it was not until July 12, 1782, that the opera was produced, and then only by express command of the emperor. It was an almost unexampled success. The work soon made the tour of Germany, and now after nearly 80 years have passed it still remains a favorite comic opera. While engaged in the composition of this work, Mozart had found that Constanza Weber was fast assuming that place in his heart which her more beautiful sister had formerly held, and tradition says that some of the exquisite music given to the lovers in the opera had its inspiration in his own emotions at that time. The envy which Mozart's success excited led to the circulation of stories dishonorable to him and Constanza Weber—stories with no foundation whatsoever. Leopold Mozart seems to have heard of them, for only after months of earnest entreaty did he give an unwilling consent to the marriage, which took place Aug. 4, 1782. Except in one respect Mozart could have made no better choice; though not extravagant, neither he nor his wife understood economy. They had several children, of whom two only survived infancy. Mozart had no reason to complain of the musical public, which was in those days small. No concerts had so large a list of paying subscribers as his; no teacher received a larger reward for lessons. As to publishing music, that for some years after Mozart's time had not become a very sure means of income. Even in case of operas, when a work was once delivered and its price (100 ducats for each of Mozart's) paid, the composer seldom derived any further advantage from it, the copyist of the theatre being usually called upon to furnish the score to any other stage which might choose to bring out the new work. It is clear that had Mozart and his wife understood the management of their income, as his father and mother had done, no pecuniary difficulties would have troubled him. As it was, at his death his debts were but 3,000 florins, some \$1,200 or \$1,500. In history Mozart occupies quite another place during those years from that in which his contemporaries beheld him. They saw a young man opening a new path and struggling upward. Gluck, Bono, Salieri, Starzer held the places which Mozart hoped in time to reach; but upon his settling in Vienna there was no vacancy. Joseph soon gave up his idea of a German opera, his taste being formed upon and remaining faithful to the Italian school, at this time represented by the popular Salieri. In 1783, as the Italian company had now complete possession of the stage, Mozart determined to obtain a libretto for himself. He applied to Varesco of Salzburg, the author of the text to *Idomeneo*, who came at once to his assistance with *L'oca del Cairo*. During a visit home, Mozart obtained the first act and set most of it to music. Upon reflection he found it so destitute of stage effect, that he laid it aside until

proper changes in the plot could be made. It was never finished. Another libretto, author unknown, was *Lo sposo deluso*, to which he composed several pieces and then laid it also aside. A few airs to a third exist among his manuscripts. One of Mozart's friends and admirers, in whose house he for a time had lived, was the baron Wetzlar. Through him the composer became acquainted with the new court poet, Da Ponte. The latter, having reason to be dissatisfied with Salieri, and conceiving that texts written by him had been unsuccessful through the inadequacy of the music, offered to prepare a libretto for Mozart. Beaumarchais' "Marriage of Figaro" was just then exciting an extraordinary sensation in Paris. Mozart saw the capabilities of the subject, and proposed to Da Ponte to make it the theme of an Italian opera text. That poet and composer should not lose their labor, Baron Wetzlar offered them a handsome remuneration in case they should not be able to bring the work upon the stage. Da Ponte began his work in the autumn, and as he gave scene after scene to Mozart, it was immediately set to music; and in 6 weeks the work was finished. Happily a new opera was just then needed. The poet saw the emperor, and related to him these particulars. As a play the "Marriage of Figaro" had been forbidden in Vienna; but the changes necessary to fit it for the operatic stage were so numerous, that the emperor finally gave permission for the performance, and ordered it to be put at once in rehearsal. The Italian party, Salieri at the head, felt the danger of having Mozart too fully appreciated. At the first performance, May 1, 1786, Mozart was obliged to go to the emperor's box after the first act to inform him that several of the singers were purposely singing false and laboring to prevent his success. This was effectual. None of Mozart's successes had been more triumphant. His opponents from this time wrought in secret, and prevented so far as possible its repetition; and it was given but 9 times, when Martin's *Cosa rara*, with its light pleasing music, long since forgotten, was received with a storm of applause, which caused the managers to withdraw *Figaro* wholly from the stage for the next two years. Before the close of the year *Figaro* was given by excellent singers and a noble orchestra in Prague. It ran the entire winter, always with crowded houses. Its success was such that Mozart was induced to visit that city. His stay there was one of the happiest periods of his existence. He and his wife were guests of Count Thurn, which threw them into the society of the highest classes, who honored him with real Bohemian enthusiasm. His concerts filled the theatre to the last place. No opera was given but *Figaro*. In the joy of his heart he said to Bondini, the director, that he must write an opera for his company. Bondini caught at the word, and when Mozart returned to Vienna, in Feb. 1787, he was under contract to compose an opera for the usual 100 ducats.

He lost no time in seeing Da Ponte, whose first text for him had proved so excellent. The poet proposed a libretto upon the old legend of Don Giovanni, which for two centuries or more had been a favorite subject for the theatre, had been wrought out in all the modern languages, not excepting the English (Shadwell's "Libertine Destroyed," performed in London in 1676), and was familiar to the Vienna public in several forms, one of them a ballet with music by Gluck. In September Mozart returned to Prague to finish his work and bring it upon the stage. A splendid performance of *Figaro*, given in honor of Prince Anton of Saxony and his wife, only increased the high expectations of the Prague public in regard to the new work, which was given for the first time on the evening of Oct. 29, the overture being played without rehearsal from parts still moist from the pens of the copyists. Though finished, Mozart did not write it out until the night before. The composer had never yet failed of success in any dramatic work which had been put upon the stage, but perhaps none, not even *Idomeneo* in Munich, had upon its first performance been received with the unbounded applause which on this evening followed number after number of *Don Giovanni*. On Nov. 8 it was given for the 4th time, and for the benefit of the composer; the house was crowded, and the receipts in proportion. Just as he reached Vienna again, Gluck died of apoplexy (Nov. 15). This made an opening for Mozart, and Joseph (who knew also that the composer was only awaiting adequate proposals to go to London) appointed him one of his chamber musicians, a sinecure with a salary of 800 florins. That the salary was so small was owing doubtless to unkind offices of his enemy Strack, chamberlain to the emperor; still it was higher than any other chamber musician received. Leopold Mozart did not live to hear of this, nor of his son's successes in Prague. A report of the first performance of *Don Giovanni* had appeared in the *Wiener Zeitung*, a novelty in its columns then, and excited a desire in Vienna to hear it. Joseph had his curiosity also aroused, and, really having a kindness for the composer, as soon as certain new works of Salieri and Martin had worn off their novelty, he commanded the production of *Don Giovanni*, in terms which left the Italians of the opera house no choice but obedience. It was given May 7, 1788, and was very coldly received. The emperor said to Da Ponte: "The opera is divine! perhaps finer than *Figaro*; but it is no food for the teeth of my Viennese." Da Ponte repeated this to Mozart. "Let them have time to chew upon it," said he. Da Ponte used his influence to have the performances of it follow each other as rapidly as possible, and the result was an astonishing success. The audience, at first surprised by its novelties, had not comprehended it. At this time a new sphere of activity opened for Mozart. Starzer, the music director of the great oratorio performances, which were organ-

ized by Van Swieten, son of the great physician of that name, died, and Mozart was engaged in his stead. In Handel's time the deficiencies of the orchestra were compensated by the organ; but, as the performances in Vienna took place in halls where there was no organ, it was necessary to supply its place by additional orchestral parts. Four of Handel's works were arranged by Mozart for Van Swieten: "Acis and Galatea" in Nov. 1788; "The Messiah" in March, 1789; "The Ode for St. Cecilia's Day" and "Alexander's Feast" in July, 1790. Notwithstanding Mozart led at this epoch a life of herculean labor, teaching, composing, and giving concerts, his pecuniary condition was gradually becoming a cause of great anxiety to him. He was plundered of his labors by singers and performers of all kinds and degrees, and of his hardly earned gold by false friends, who stole under the polite name of borrowing. His fame was however extending, and his works, notwithstanding their novelties, gaining a universal appreciation. He had been long laying the foundation upon which nothing but an early death could prevent him from raising a glorious edifice; he had planted the seeds, which must inevitably produce him a rich harvest both in reputation and pecuniary reward. But the time was not quite yet. It was a most welcome invitation which he received from Prince Charles Lichnowsky in the spring of 1789 to share his carriage and journey with him to North Germany. They left Vienna April 8, and reached Dresden upon the 12th. In this city Mozart played at court, receiving a golden snuff box in return. In Leipsic his reception was all he could wish. Doles, a pupil and successor of Bach in the Thomas school, found his organ playing precisely that of his old master. Every thing conspired to raise the spirits and hopes of Mozart. In Berlin, Dupont the great violinist used all his influence against him with the king, but with no success. Frederic William II. was too good a musician and understood Mozart's music too well to be influenced by the intriguing Frenchman. The king, too, upon further acquaintance with Mozart, took such a liking to him personally as one day to offer him the place of chapelmaster with 8,000 thalers salary. Mozart felt himself bound, out of regard to the emperor, to refuse the offer at least for the present. The king told him it should remain good for a year and a day. After an absence of some 3 months Mozart returned to Vienna. The pecuniary results of the journey were not very splendid, and a dangerous sickness of his wife which soon followed exhausted them. For a quartet which he now wrote and sent to the king of Prussia, he received a gold box containing 100 friedrichs d'or. Upon his return from Berlin he had said nothing at first of Frederic William's offer; but, urged by his friends, he at length saw the emperor, explained the sad condition of his pecuniary affairs, and closed by requesting his dismissal. Joseph was very unpleasantly surprised, and exclaimed with emotion:

"What! you will leave me, Mozart?" Mozart was touched, and replied: "Your majesty, I throw myself upon your mercy, and will remain." Joseph was now bound by every honorable consideration to provide for him, nor was the disposition wanting. The opera *Così fan tutte* was placed in his hands for composition. It was produced Jan. 26, 1790, and was running successfully, when the emperor died, before he had given the composer any certain provision beyond his 800 florins as chamber musician. It was sufficient for the new emperor, Leopold, that Mozart had been favored by Joseph; and Mozart's two petitions, one for the now vacant chapelmastership, the other to be appointed pianoforte instructor of the young princes, were refused. Indeed, Leopold's enmity went so far, that when the musicians in Vienna were called to court to play before the king of Naples, Mozart was ignored. In the autumn Mozart visited Frankfort-on-the-Main, Mentz, and Mannheim, upon occasion of the coronation of Leopold as German emperor. He gained much fame, and gave successful concerts; but his expenses were necessarily so large, that he brought home but little money. In Munich he was invited to court to play before the king of Naples, who happened to be there. "Very honorable to the court at Vienna that the king could only hear me in a foreign land!" he wrote to his wife. He was still poor and pressed for money, but fortune was at length turning. Soon after his return John Peter Salomon came to Vienna to engage Haydn to compose for and direct in his concerts at London for a season or two—an engagement of the highest value to him, as it proved; and Mozart was engaged to follow. Early in the spring his old acquaintance Schikaneder, now established in Vienna, and proprietor of the small theatre in the suburb of Wieden, where fairy dramas and farcical comedies were given for the populace, applied to him to compose the music to one of these magic pieces. Mozart agreed to do so, but said he could not be responsible for its success, as he never had tried his hand at this kind of composition. The subject was the *Zauberflöte*, or "Magic Flute." Constanza Mozart was in Baden at the sulphur baths, and her husband while engaged upon the *Zauberflöte* was therefore thrown much more exclusively into the society of Schikaneder, a votary of wine, women, and a rich table. With him and his merry companions the disappointed and harassed composer could forget his troubles. The manager caused the champagne to flow freely, heaped the table with delicacies, and for some 10 or 12 weeks, the first and only time in his life, was Mozart induced to break in upon his temperate, even abstemious habits. It is due to his memory to state this, and deny in the most emphatic manner the stories which have found footing in all musical literature to the disadvantage of his reputation, except in so far as they are founded upon this short period. One other point deserves a word. Rochlitz has

recorded that Schikaneder cheated Mozart not only out of his remuneration for the composition, but out of the score afterward. Jahn has proved that Rochlitz in his anecdotes of Mozart is full of mistakes, not to use a harsher term. Seyfried assures us that Schikaneder paid the composer 100 golden ducats. On May 9 the magistrates of Vienna appointed Mozart as adjunct and successor to the chapelmaster Hoffmann, of St. Stephen's church, the best musical position except the imperial chapelmasterhips in Vienna, and one exceedingly to his taste. In July a messenger unknown to Mozart—his name was Leutze—brought him an anonymous letter in which, after speaking warmly of the composer's genius, his terms for a requiem were demanded. Mozart gave them, and soon after the messenger returned and paid him 50 ducats (or according to some authorities 100) in advance. Da Ponte, now established in London, had written to him to come thither and produce his operas, to which Mozart replied that the *Zauberflöte* would render the journey impossible under 6 months. This was not all. In August came an order from the magistrates of Prague to compose the opera "Titus," to be performed Sept. 5, upon occasion of the coronation of Leopold as king of Bohemia. But 4 or at most 5 weeks remained for the entire labor of composition and rehearsal of the *Clemenza di Tito*, one of Metastasio's texts. With all speed Mozart made his preparations, and, taking his wife and his pupil Süßmayr with him, he started for Prague. As they were entering the carriage at their own door, some one pulled Mme. Mozart by her dress. She turned, and saw the man who had ordered the requiem. Mozart explained the necessity of the present journey, and promised that that work should be his first labor upon his return. On reaching Prague there were but 18 days left before the opera was to be given. Fortunately for him, his pupil was so thoroughly acquainted with Mozart's style of composition, that his master could give the score into his hands after the vocal parts were written and the accompaniment sketched, to be filled out. In this manner the work was completed in time. It was not however received as his other operas had been, which is easily to be accounted for, both in the character of the libretto, and in the fact that such a subject was hardly one fitted for an occasion when all Prague was in the mad excitement of a coronation. The opera afterward became very popular, and still keeps the stage. In September Mozart reached Vienna again, sick and disappointed, to divide his time between the "Magic Flute" and the requiem. On the 30th of that month the opera was given, Mozart directing. To the end of the first act the audience remained cold, but warmed up before the close, and Mozart was called before the curtain. But with each performance its popularity increased. In October alone it was given 24 times. Operatic history gives no instance of a drama so feeble, which became so univer-

sally popular. Perhaps the greatest compliment that could be paid it is the fact that Goethe wrote a second part to it. Now came the requiem, to which Mozart gave all the strength of his powers, all the force of his genius. As he had been unable to learn the name (a Count Wallsegg) of him who had ordered it, he began to fancy something supernatural in the affair. In fact, the anxieties of the preceding year, possibly the change in his habits while under the influence of Schikaneder, and his too great exertions upon the "Titus" (he was ill when he went to Prague, and came home still more so), all together had reduced him and brought his nervous system into a condition which required a long period of rest and recreation. This he denied himself. He had had several fainting fits while engaged upon the *Zauberflöte*; and the restless energy with which he now wrought upon the requiem enfeebled him daily. His wife became anxious, called a physician, and took away the score. He fancied that some one had given him poison. In November he was so much better as to write a cantata for the masonic lodge to which he belonged, "Praise of Friendship." Just at this time a sort of rheumatic inflammatory fever was epidemic in Vienna. In the enfeebled state of Mozart's naturally delicate constitution, it seized upon him. Inflammation of the lungs led to dropsy of the chest, and after two weeks' confinement to his bed he died. On the last day of his life he busied himself with the requiem, which he now fancied he was composing for his own obsequies, but died leaving it unfinished. The widow was in no position to return the money which had been received for it, and the question was whether it could not be completed from the rough notes made by the deceased; but for several portions no such memoranda existed. Süßmayr had, however, so often conversed with Mozart upon the plan of the work, and had become so thoroughly familiar with his style, that he undertook to finish it. As his hand had a remarkable similarity to that of his master, this now came into play. All that Mozart had written was copied, and the rest, consisting of the close of the *Lacrimosa*, the *Sanctus*, the *Benedictus*, and the *Agnus Dei*, was added by him, save that to the words *Cum sanctis* he repeated the fugue of the *Kyrie*. When the messenger came for the requiem, this score was given him; and its authenticity as a manuscript from Mozart's hand was never suspected by Wallsegg until the topic began to be discussed by the press. While Mozart lay sick, the Hungarian nobility secured to him an annual pension of 1,000 florins, and a musical association in Amsterdam a still higher annuity, for which he was to deliver certain compositions annually.—In this sketch, being confined to the leading points in the life of the composer, we have been unable to give any adequate idea of the vastness of the mass of his compositions during his short life of 36 years. More than 800 works

are known—for the pianoforte in all forms, variations on a simple theme, works for two pianofortes, and up through all gradations to the concerto, with full orchestra; for orchestral instruments of every kind, from solos to the grand symphony; there are even compositions for Franklin's harmonica, and a piece for a musical clock. Equally universal is he in vocal music, from songs and airs for every kind of voice, to the opera and church music in all its forms as employed in the Roman Catholic service. But it is not so much the quantity as the excellence of his music which excites the astonishment of the musician. This was owing not more to the greatness of his genius than to his profound studies, which from infancy to the close of his life never ceased. During the rehearsals of *Don Giovanni* at Prague, in a conversation with the chapelmaster Kucharz, he remarked, in reply to praises of the new work: "People err if they think my art has cost me no trouble; I assure you, my dear friend, no one has taken such pains with the study of composition as I. There is hardly a celebrated master in music whom I have not carefully, and, in many cases, several times, studied through." Hence it was that he could so infallibly decide upon the originality of his musical ideas, and always avoid whatever did not bear the stamp of his own genius. Two generations of musicians have been educated upon the works of Mozart. His ideas have become common stock; and effects which, if now introduced into a composition, would sound hackneyed, were in his works the joint production of lofty genius and profound contrapuntal knowledge, guided and restrained by exquisite taste. As an instrumental composer perhaps one only has surpassed him, Beethoven; but Beethoven had his works to study. Haydn had developed the quartet form and invented the grand symphony. Mozart gave them a new spirit, and one sees his influence in all Haydn's later works. That great master said to Leopold Mozart in 1785: "I tell you before God and as a man of honor, that I look upon your son as the greatest composer of whom I ever heard; he has taste, and possesses the most thorough knowledge of composition." The symphony in C with the fugue is alone sufficient proof of the correctness of Haydn's opinion; it is the greatest work of the kind ever written before Beethoven. It was as an operatic composer, however, that Mozart reached a height upon which, like Handel in oratorio, and Bach in his own contrapuntal sphere, and Beethoven in orchestral music, he stands superior to all his predecessors.—KARL, his last surviving son, attended the centennial celebration of his father's birth at Salzburg in 1856, and died at Milan, Oct. 31, 1858, leaving a large fortune.

MUCILAGE, in pharmacy, a solution of gum or other similar body in water. It is employed chiefly in the formation of pills and for the diffusion of insoluble substances in water.

Mucilage of gum Arabic is a preparation much used as a paste. Its tendency to become sour by standing is checked by the addition of a few drops of any essential oil.—Berzelius applied the term mucilage to a proximate vegetable principle distinguished from gum by being insoluble in cold water. In boiling water it swells and forms a mucilaginous viscid body, which loses its moisture when placed upon porous paper, and contracts like starch in the gelatinous state. This is not, however, properly a distinct proximate principle, as it embraces a number of different bodies, as bassorine, cerasine, &c.

MUCUS SCÆVOLA. See **SCÆVOLA**.

MUCK. See **BOG EARTH**.

MUCOUS MEMBRANE. See **MEMBRANE**.

MUCUS, the fluid which moistens the mucous membranes, the secretion of their numerous glandules or follicles; these are lined by cylinder epithelium, the coating of mucus being furnished by the continual disintegration and renewal of its component cells. Mucus consists in great part of epithelial cells floating in a clear viscid fluid; it is generally alkaline, and contains, according to Berzelius, when these particles have subsided, 54 per cent. of proper mucous matter; pure mucus, according to Scheerer, contains 52.17 per cent. of carbon, 28.18 of oxygen, 12.64 of nitrogen, 7.01 of hydrogen, and 4.10 of saline matter. Its properties are variously altered by disease, sometimes becoming acid, mixed with pus, or otherwise changed. All secretions poured upon mucous membranes are more or less mingled with mucus, as the saliva, biliary and other digestive fluids, and the urine. From the saliva it subsides as an opaque whitish matter; it forms the residue after bile is treated with alcohol, and to its presence is probably due the rapid decomposition undergone by biliary matter; from urine it generally falls as a delicate film, but in inflammations of these passages is poured out in great quantities, quickly undergoing decomposition, and exciting ammoniacal changes in the urea, passing off as a thick tenacious sediment; it also becomes very thick in inflammations of the respiratory and alimentary passages. Its principal office is to protect the mucous surfaces from injury by the contact of foreign substances or the action of normal or diseased excretions and secretions, and to lubricate the canals in which they pass in or out of the body.

MUD FISH (*amia*, Linn.), a genus of American ganoids, found in the fresh waters of the United States. After having been referred by ichthyologists to cyprinoid, salmonoid, and clupeoid fishes, Vogt discovered it to be a ganoid, having found in the muscular arterial trunk 2 oblique rows of 5 or 6 valves each and a spiral intestinal valve. Müller considers it the living representative of a ganoid family, like the fossil *megalurus*, *leptolepis*, and their congeners. The body is long and flexible, with a bony vertebral column; there are no spiny plates on the anterior border of the fins as in the gar fish, nor a series

of separate dorsal fins as in *polypterus*; the mouth is trout-like, except in the absence of lingual teeth; there are 2 nasal cirri; the head is flat, and the bones under the very thin skin are sculptured plates; the large sublingual bone is naked and furrowed, the gill openings large, and the branchiostegal rays broad and flat, 11 or 12; tongue thick and fleshy; behind the conical teeth of the jaws are flat pavement-like ones; the scales are horny rather than osseous, flexible and rounded, yet presenting bone corpuscles of the same form and character as *lepidosteus* and other ganoids; the ventral fins are median, the single dorsal long, and the anal short; the caudal comes further forward above than below, rounded, giving an indication of the heterocercal tail. The larger air bladder is cellular and lung-like, communicating with the oesophagus; no pancreatic caeca; ova dropping into abdominal cavity. Of about 10 species, the best known is the western mud fish (*A. cales*, Linn.), from 1½ to 3 feet long; the back of the head is bluish black, the sides often obscurely spotted with olive, white below, and with a black spot at the upper edge of the caudal. It is found in the great northern lakes, south to Carolina, and west to the Mississippi; it is the bowfin of Lake Champlain, the dog fish of Lake Erie, and the marsh fish of the Canadians; it feeds on crawfish and other crustaceans, and is occasionally eaten by the Indians. This may include several species.

MUD HEN. See COOR.

MUDGE, WILLIAM, an English engineer, born in Plymouth in 1762, died in London, April 17, 1821. He was educated at Woolwich, entered the artillery, served on the continent, and after his return to England became assistant to Lieut. Col. Williams, whom he ultimately succeeded as superintendent of the trigonometrical survey of England and Wales. In 1799 he published, in conjunction with Mr. Isaac Dalby, one of his associates, the first volume of "An Account of the Survey from the Commencement in 1784 to the End of the Year 1796." The 2d and 3d volumes of this work, continuing the account to 1809, appeared in 1801 and 1811. He was successively promoted to the rank of captain, major, lieutenant-colonel, and major-general in the army. During the latter part of his life he was also lieutenant-governor of the military academy at Woolwich.

MUDIE, ROBERT, a Scottish author, born in Forfarshire, June 28, 1777, died in London, April 20, 1842. He was entirely self-educated. In 1802 he was appointed professor of Gaelic and teacher of drawing in the Inverness academy. In 1820 he went to London, and became a reporter for the "Morning Chronicle," but was afterward involved in difficulties, and his career ended unhappily. He is said to have written and published over 80 volumes, of which his works on natural history and philosophy are the most valuable and interesting. The principal of these are: "The British Naturalist;" "The Feathered Tribes of the British Isles;"

"The Elements: the Heavens, the Earth, the Air, the Sea;" "Popular Astronomy;" "The Four Seasons;" and "Man, Social, Intellectual, Moral, Physical."

MUEZZIN, an officer of a mosque in Mohammedan countries, who calls the faithful to prayer at the 5 times in the day prescribed by the Koran, viz.: at dawn, noon, 4 P. M., sunset, and nightfall. He commonly stands on the balcony of a minaret and chants in a loud voice the following formula: "God is great! There is no God but Allah, and Mohammed is the prophet of God! Prayer is better than sleep! Come to prayer!" As from his elevation on the minaret the muezzin can overlook the roofs and the interior of dwellings, which is extremely distasteful to the jealous orientals, it is usual to confer the office on blind men; and many curious tales are current in the East of men who have feigned to be blind in order to become muezzins to wealthy mosques.

MUFTI, a Turkish doctor of divinity, or of the law of the Koran. There is one in every large town. The mufti of Constantinople, or grand mufti, called also *Sheikh-ul-Islam*, "chief of Islam," is the head of the Turkish church. He takes rank immediately after the grand vizier, and has great authority and influence. Though he is appointed by the sultan and holds office at the imperial pleasure, he cannot like other officers be legally put to death nor stripped of his property. He is the chief interpreter of the law, and formerly no person could be subjected to capital punishment without his consent. His opinion was required by placing before him a written statement of the case with fictitious names; and, without assigning any reasons, he gave his judgment by writing on the document: "He shall (or shall not) be punished;" or in a doubtful case: "God knows best." The reorganization of the Turkish government, and the establishment of a ministry like that of other European nations, has of late years much curtailed the power and prerogatives of the grand mufti.

MÜGGE, THEODOR, a German novelist, born in Berlin, Nov. 8, 1806. He was in commercial and military life previous to his academical studies. Among his more important novels are: *Die Venedigerin* (8 vols., Berlin, 1837); *Tänzerin und Gräfin* (2 vols., Leipzig, 1839); and particularly *Toussaint Louverture* (4 vols., Stuttgart, 1840), which gives graphic descriptions of the struggle in Hayti. Among his more recent productions are *Der Weihnachts-Abend* (Berlin, 1858), and *Afraga* (1854). The latter, a Norwegian and Lapland tale, was translated into English by Edward Joy Morris (Philadelphia, 1854; 4th ed., 1858), and a French translation of it is included in the *Collection des meilleurs romans étrangers* (Paris, 1857). An English translation of his "Switzerland," edited by Mrs. Percy Sinnett, was published in London in 1848. He was in 1850 one of the founders of the *Berliner Nationalzeitung*, and for some time conducted its literary department.

His novel *Aero Spang*, treating of Norwegian life, was published in 1860.

MUGGLETON, LUDOWICK, an English fanatic, who in conjunction with John Reeve founded the sect of the Muggletonians, born in 1609, died in March, 1698. In 1651, abandoning his trade, that of a tailor, he proclaimed himself and Reeve the "two last witnesses" mentioned in the Apocalypse, and armed with power to prophesy and to punish men. They commenced their mission by denouncing all religious sects, especially Ranters and Quakers. In 1656 appeared an exposition of their doctrines under the title of "The Divine Looking Glass." They held that God has the body of a man, that there is no distinction of persons in the Trinity, and that God, descending to earth and suffering on the cross, left Elias as his vicegerent in heaven during his absence. They were attacked by William Penn in a book called "The New Witnesses proved Old Heretics." Muggleton was arraigned at the Old Bailey for blasphemy in 1676. The first complete edition of his works was published in 1756. In 1832 another edition appeared in 8 vols. 4to., which included not merely his own rhapsodies, but also those of his coadjutor Reeve, together with several tracts by others of the sect.

MUHLENBERG, I. PERER, a major-general in the American revolutionary army, son of Henry Melchior Muhlenberg, D.D., the founder of the German Lutheran church in America, born at Trappe, Montgomery co., Penn., Oct. 1, 1746, died near Philadelphia, Oct. 1, 1807. He was educated for the ministry, was ordained in England, and preached at Woodstock, Va. His last sermon was upon the duties men owe their country; and saying: "There is a time for all things—a time to preach and a time to fight—and now is the time to fight," he stripped off his gown after the service, appeared in full uniform, read his commission as colonel, and formed a regiment among his parishioners. He participated in several battles, was made brigadier-general in 1777, and major-general at the close of the revolution. After the war he removed to Pennsylvania, where he was elected a member of the supreme executive council, and in 1785 became vice-president of the commonwealth. He served as representative in congress from 1789 to 1791, from 1793 to 1795, and from 1799 to 1801. In 1801 he was elected U. S. senator, but resigned the next year, and was appointed supervisor of the revenue for the district of Pennsylvania. From 1808 till his death he held the office of collector of the port of Philadelphia. II. HENRY ERNER, D.D., an American clergyman and botanist, brother of the preceding, born in New Providence, Montgomery co., Penn., Nov. 17, 1758, died in Lancaster, May 28, 1815. At the age of 10 he was sent to the university of Halle in Germany, and remained there till 1770, pursuing a course of literary and theological study. In that year he returned to America, was ordained by the Lutheran synod, and became in

1774 third minister and assistant to his father, then pastor of the Philadelphia congregation. During the occupation of Philadelphia by the British in 1777, he retired to the country, where he devoted himself to the study of botany. In 1780 he became pastor of the church at Lancaster, and there remained till his death. His scientific attainments were extensive, but in botany he was especially distinguished. He became a member of the American philosophical society in 1786, of the *Gesellschaft Naturforschender Freunde* in Berlin in 1798, of the philosophical and physical societies of Göttingen in 1802, and of various other associations in Sweden and Germany. His chief works are: *Catalogus Plantarum Americae Septentrionalis* (Lancaster, 1818), and *Descriptio Ueberior Graminum*.

MÜHLENBRUCH, CHRISTIAN FRIEDRICH, a German jurist, born at Rostock, Oct. 8, 1785, died in Göttingen, July 17, 1848. He was successively professor at Rostock, Greifswalde, Königsberg, Halle, and from 1838 till his death at Göttingen. He ranks among the most eminent jurists of the present century. Among his works are: *Doctrina Pandectarum* (Halle, 1823-'5), and *Lehrbuch des Pandektenrechts* (1836-'7), which have passed through many editions.

MUHLBURG, a W. co. of Ky., bounded N. E. by Green river and W. by Pond river, its principal branch; area, 480 sq. m.; pop. in 1850, 9,809, of whom 1,522 were slaves. The surface is hilly and the soil generally fertile. It contains coal and iron mines near Green river. The productions in 1850 were 495,828 bushels of Indian corn, 74,020 of oats, 685,050 lbs. of tobacco, and 20,250 of wool. There were 10 grist mills, 5 saw mills, 1 tannery, and 87 churches. Capital, Greenville.

MÜHLHAUSEN, a town of Prussia, province of Saxony, on the Unstrutt, 20 m. N. W. from Erfurt; pop. about 14,000. It is surrounded with walls, and was formerly a free city of the empire. It is chiefly memorable for having been the head-quarters of Münzer, the leader of the peasants' war, and the scene of his execution in 1525.

MÜHLHAUSEN, a town of France. See MULHOUSE.

MULATTO (Sp. *mulato*, from *mulo*, a mule), the offspring of parents one of whom is black and the other white. The mulatto is of yellowish color with frizzled hair, and in features and disposition exhibits commonly more resemblance to the white than to the black race. Mulattoes are numerous in the United States, and are still more abundant in the West Indies and in Spanish and Portuguese America. In the old world many individual mulattoes are found in Turkey, Arabia, Persia, and India, and on all the coasts of Africa. In south Africa the people called the Griquas are mulattoes, descended on one side from the Dutch and on the other from the Hottentots. In northern Africa the population of Egypt and of the Barbary States has been from remote antiquity to a great degree of mulatto origin. The republic of Do-

minica in the island of Hayti, the oldest civilized community in the western hemisphere, is almost entirely composed of mulattoes.

MULBERRY, the name of various trees and their fruit, belonging to the natural order *urticeae*, and constituting a group by themselves. The black or common mulberry (*morus nigra*, Linn.) is a deciduous tree, native of Persia, growing from 20 to 30 feet high, with an irregularly branching top, cultivated in England ever since 1548. The leaves are broadly heart-shaped, unequally serrate, and very rough; the fruit is sessile, of a dark purple color, and, though called a berry, is in fact a spike, composed of the succulent, conglomerated axes, calyxes, and carpels. The flowers of the mulberry tree are either monœcious or diœcious, and have a 4-parted calyx, ovate sepals, 4 stamens, the filaments of which elastically expand, an ovary of 2 cells, one of which disappears, and 3 filiform styles. It is asserted that this species lives for a long time, individual specimens of the tree being known in England more than 800 years old. Its roots are equally tenacious of life. The ancients seem to have been acquainted with the species, it being mentioned by Ovid and Pliny, the latter calling it the "wisest of trees," because it is so slow in putting forth its leaves. Mention is likewise made of it in the Sacred Scriptures. Shakespeare's mulberry, which was planted in his garden at New Place, Stratford, was the black mulberry, as is well ascertained. The black mulberry is cultivated for its fruit, which is very wholesome and palatable. When to be used at the dessert, it should be freshly gathered and be so ripe as to drop from the tree. From the fruit a sirup is prepared, thought excellent for sore throats; and sometimes its juice is mixed with that of apples, forming a deep port-wine-colored beverage known as mulberry cider. The black mulberry grows very well as far north as Massachusetts, and Downing mentions it as thriving on the Hudson river 80 miles above the city of New York. It may be propagated from seeds, cuttings, or layers, the last being the surest and best way, as thereby the finest varieties having monœcious flowers can be secured. It thrives best in a light, rich, and moderately dry soil.—The red mulberry (*M. rubra*, Linn.) is a native species, with large, rough, heart-ovate, serrate (and on the younger shoots, lobed) leaves, and dark purple fruit, found wild in rich woods from New England to Illinois and southward. Its stem rises to the height of 15 to 25 feet or even more, with numerous spreading branches at the summit. Its flowers are greenish, small, and numerous. Its wood is exceedingly durable, and valued for making posts. Its fruit, according to Darlington, is more admired than that of any other species.—The white mulberry (*M. alba*, Linn.) is an adventitious tree from Europe, becoming naturalized around houses. Its stem attains the height of 20 to 25 feet, and has a much branching top. Its leaves, espe-

cially in the younger plants, are large, from 4 to 12 inches long, partially lobed, unequally crenate, serrate, and borne on petioles an inch long, having lance-linear stipules at their bases. The fruit, when mature, is of a pale yellow color, but sometimes inclining to a dark purple tint. It is a native of China and Persia, and was introduced into England with the black mulberry, and into America about a century since. The foliage of the white mulberry is preferred in the raising of the silkworm, although the other species will answer if their leaves are young and tender. A variety with larger foliage and of a smaller sized stem was in much repute some years since, known as the many-stemmed mulberry (*M. multicaulis*), and attracted universal attention. It was described by Kenrick ("New American Orchardist," Boston, 1835) as differing from all others in the property which the roots possessed of throwing up numerous flexible stalks, for the great length which these stalks acquired in a short space of time, for the facility of propagation from cuttings and layers, and for the thinness and succulency of the leaves; in a rich and humid soil its growth was extremely rapid, and prolonged to a late period in the autumn. Its fruit is said to be edible, and is probably similar to that of the white mulberry.—The paper mulberry (*Broussonetia papyrifera*, Ventenat) was introduced into the United States a few years ago as a shade tree; but on account of its producing so many suckers from its roots, it was soon considered unfit for the purpose. Its trunk reaches to the height of about 25 feet; its leaves are mostly undivided, roundish ovate or subcordate, rough above, downy beneath, 3 to 8 inches long, supported by petioles 1 to 3 inches in length; the flowers are diœcious, the staminate being in a sort of loose aments, and the pistillate in dense clustered heads. From the inner bark of the trunk, a kind of tough paper, used as a substitute for cloth, is prepared by the South sea islanders. The India or China paper, used for taking proofs of engravings, is also made of the inner bark. The wood however is soft, spongy, and of little value. The Japanese, according to Kimpfer, reduce the bark to a soft pulp and dry it in sheets, somewhat like the old mode of European paper making.

MULDER, GERARD JOHANNES, a Dutch chemist, born in Utrecht in 1802. He studied medicine at the university of Utrecht, and in 1825 established himself in Amsterdam as a practising physician. In 1827 he was appointed lecturer on botany and chemistry in the medical school of Amsterdam, but resigned the office in 1830 because his practice absorbed his time. In 1841 he became professor of chemistry at Utrecht, a position which he still holds. His chief work is his "Chemistry of Vegetable and Animal Physiology," translated into English by Dr. Fromberg, in which he deduced as the result of a number of original inquiries the existence in animals of a substance which he calls "pro-

teins," which they derive ready formed from plants. The results of this discovery are announced by Dr. Johnston, in an introduction to the English edition of Mulder's work, to be as follows: "1. That this proteine formed the basis of a large group of animal substances, the albuminous group, comprising fibrine, albumen, caseine, the crystalline lens of the eye, the hair, horn, &c. 2. That in these substances the proteine was combined with oxygen, sulphur, or phosphorus, or with two of these bodies, or with all the three; and that the proportions of these separate elements determined the special qualities of each compound of the albuminous group. 3. That the sap and leaves, but especially the seeds of plants, contained proteine in combination with sulphur and phosphorus as it is found in the animal body; and that the gluten of wheat, the legumine of the bean, and the nitrogenous substances generally which are found in the seeds of plants, were compounds of this kind. 4. That these substances were formed by the plant out of the food drawn by its several parts from the air and from the soil; that it produced them for the purpose of diminishing the digestive labor, so to speak, of the animal, of supplying it with food fitted directly to form and nourish its muscular and albuminous parts; and that the animal received its whole supply of the raw material out of which these parts were to be built up from the vegetable food on which it lived." The publication of this discovery involved Mulder in a controversy with Liebig, who doubted the existence of proteine as an independent chemical compound; his reply to the latter has been translated into English by Dr. Fromberg.

MULE. See Ass.

MULGRAVE or **MILLE ISLANDS**, a group in the southern part of the Radack chain, which forms the eastern part of the Marshall archipelago in the N. Pacific ocean. Their extent is not very well determined, but the surrounding reefs have been examined for about 40 m., and after a careful search only one pass for ships and another for boats could be found. Some of the islands are mere coral rocks covered by the sea at high tide, but nearly all have deep water close to the reefs. When they reach the level of the water, however, they become, like the islands already formed, covered by sand and vegetation. Some of them are of considerable size, and have clumps of cocoanut and bread-fruit trees.

MULGRAVE, **CONSTANTINE JOHN PHIPPS**, baron, an English navigator, born in 1744, died in 1792. He early entered the British navy, commanded a north-east arctic exploring expedition in 1773, and returned the same year after having reached lat. 80° 48' N., beyond which an impenetrable field of ice stretched as far as could be seen. Lord Mulgrave was afterward commissioner of the admiralty. He published a "Journal of a Voyage toward the North Pole" (London, 1774). His brother, afterward created Viscount Normanby

and Earl Mulgrave, served with distinction in the British army during the American war.

MULGRAVE, **JOHN SHEFFIELD**, earl of, marquis of Normanby and duke of Buckinghamshire, an English statesman and poet, born in 1649, died Feb. 24, 1721. He was mostly self-educated. At the age of 17 he volunteered in the navy, but did not see an action, and soon after was appointed to the command of a troop of horse. In 1672 he entered the navy again, sailed under Lord Ossory, and was shortly promoted to the command of a ship; but forsook the sea a second time and raised a regiment of foot, of which he acted as colonel during the Dutch war. He entered the French service to learn the art of war under Turenne, and on his return to England was appointed lieutenant of Yorkshire and governor of Hull; but having presumed to aspire for the hand of the princess Anne, the king sent him in 1680 to relieve Tanguier from the Moors, with the intention, it was said, that he should perish in the leaky vessel which carried him. On his return he was restored to favor, and on the accession of James II. was made lord chamberlain and admitted to the privy council and the high commission. He made his submission to William of Orange, was created marquis of Normanby in 1694, afterward obtained a seat in the cabinet, became lord privy seal (1702), and lord lieutenant of the north riding of Yorkshire under Queen Anne, and in 1707 was made first duke of Normanby and then of Buckinghamshire. Through jealousy of Marlborough he resigned the privy seal and joined in a motion for inviting the princess Sophia to England. On the change of ministry in 1710 he became lord chamberlain of the household. Under George I. he held no office.—Like Montague and some other titled rhymesters of the period, Lord Mulgrave is best known by what is really his slightest claim to be remembered. His most famous work is the "Essay on Satire," which he is thought by some to have written in conjunction with Dryden, and for which Dryden received a beating at the instigation of the earl of Rochester, though he probably had no hand in it beyond revising it. Lord Mulgrave's "Essay on Poetry" was praised by Dryden and Pope, but is now forgotten.

MULHOUSE, **MÜHLHAUSEN**, or **MÜLHAUSEN**, a town of France, in the department of Haut-Rhin, on the Ill, 804 m. S. E. from Paris, 19 m. W. from Basel, and 70 m. from Strasbourg; pop. in 1856, 29,574. It consists of an old and a new town; the former upon an island, the latter on the right bank of the Ill. Since the beginning of the present century Mulhouse has become one of the important seats of industry in France. Upward of 7,000 persons from the country now daily resort for employment to the town. An entirely new quarter has recently sprung up, chiefly peopled by those engaged in the manufacture of cotton prints and muslins. Cotton printing was first introduced there in the middle of the 18th century by Samuel Koechlin, whose descendants

are still, under the firm of Koechlin brothers, at the head of the principal manufactures. The Naghelin spinning factory employs nearly 100,000 spindles. Most of the manufacturers of Mulhouse received medals at the French exhibition of 1855. The prosperity of the town is rapidly increasing. Mulhouse and its territory once formed part of the Swiss confederation, but were united to France in 1798.

MULL, an island of the Hebrides, forming part of Argyleshire, is situated in the Atlantic ocean, and separated from the mainland by a narrow strait termed the sound of Mull; area, 801 sq. m.; pop. in 1851, 8,869. The coast is rocky, and deeply indented. The surface is mountainous, Benmore, its highest summit, attaining an altitude of 8,168 feet. The most remarkable natural objects are the caverns and basaltic columns and arches that occur around its shores. The soil is chiefly devoted to pasturage. Herring and white fish are caught off the coasts. Mull is subdivided into 8 parishes, and contains several villages, the most important of which is Tobermory near the N. E. extremity of the island.

MULLEIN, the name of biennial herbs of the genus *verbascum*, belonging to the natural order of *scrophulariaceae*, having a persistent calyx, an irregular, personate corolla, 5 stamens, the 5th being destitute of anther, or only 2 stamens, the 2d pair being suppressed or abortive. The common mullein (*V. thapsus*, Linn.) is a tall plant, introduced from Europe, and growing universally upon thin, sandy, and sterile soils, marking by its excessive abundance a negligent husbandry. The lobes of the corolla are only a little unequal, the stamens are 5 in number, all the filaments of which, or at least the 3 upper, are woolly; the style is flattened at its apex; the capsule is ovoid or globose, and filled with numerous, rugose-pitted seeds. The flowers are conspicuously showy, in a dense terminal spike, and of a handsome bright yellow color. The entire plant is covered with a hairy, tomentose pubescence, which renders the large radical leaves soft, like the cloth of velvet; the hairs are stellate, each hair composed of 7 primary rays with smaller and more delicate intermediate ones. The properties of the mullein, according to Lindley, are poisonous in the seeds and flowers; the foliage is acrid and bitterish. As a domestic remedy in sore throat, the broader leaves are dried and bound around the throat to produce a slight local irritation. Were it not for its rapidity in covering neglected fields by the vegetating of its innumerable seeds falling around, the mullein might be more esteemed on account of its commanding and showy exterior, and perhaps hold a place in the garden. The moth mullein (*V. blattaria*, Linn.) has a stem 2 to 5 feet high; its leaves are 2 to 6 inches long, the lower differing in shape from the upper, which are sessile and clasping, while the former are petiolate and sometimes pinnatifid; its flowers are borne upon a long, leafy raceme; each flower is

exserted on a pedicel about an inch long, which renders the spike lighter and more open; the color of the flowers is either a bright yellow or white tinted with purplish. The moth mullein has become a rather familiar weed in Pennsylvania; in Massachusetts it is only seen by the wayside as an estray from some garden. Under cultivation it blossoms from July till the early frosts, and is esteemed as a border plant, the white flowering variety being preferred. The white mullein (*V. lychnitis*, Linn.) is an adventitious plant from Europe, and is to be found in some localities by the roadsides in Pennsylvania and in sandy fields in portions of the state of New York; its stem and branches are angled above, and clothed with a thin, powdery wooliness; its leaves are ovate, acute, not decurrent, green on their upper surface; its flowers are usually yellow, and are borne on a pyramidal panicle. This species is said to hybridize freely with the common mullein. There are several other species of *verbascum*, some of which are to be met with in gardens on account of their flowers. Persoon enumerates as many as 25 growing spontaneously in the temperate regions of the globe.

MÜLLER, ALBERT A., an American clergyman and poet, born in Charleston, S. C., about 1800. He was educated in that city, and published in 1825 a volume of poems which attracted much attention. One of his lyrics, after being generally copied by the newspapers, was finally adopted into the early American editions of Moore's sacred or Hebrew melodies, of which it formed the opening poem. He afterward went to the south-west, and all traces of him have been lost.

MÜLLER, CHARLES LOUIS, a French painter, born in Paris, Dec. 27, 1815. He studied with Cogniet and in the school of fine arts, and first exhibited in 1837; from 1850 to 1858 he was director of the manufactory of Gobelins tapestries. Among his chief works are the "Martyrdom of St. Bartholomew," the "Massacre of the Innocents," "Primavera," "Lady Macbeth," and the "Appeal of the Victims of the Reign of Terror;" the last, a large piece containing many portraits of historical persons, is his most powerful work. Another large historical picture by him, entitled *Vice Rompueur*, illustrating an episode in the battle before Paris, March 30, 1814, attracted much attention at the great exposition of 1855, and secured for the painter a medal of the first class. To distinguish him from the numerous painters of his name, he is called "Müller of Paris."

MÜLLER, FRIEDRICH, a German painter and poet, born in Creuznach in 1750, died in Rome, April 23, 1825. He early devoted himself to painting and copperplate engraving, and in his 18th year published several collections of etchings, which attracted much attention from their originality. In 1776 he went to Rome, and studied the works of Michel Angelo; but his taste for the grotesque constantly increased and gave a fantastic character to his productions.

He stands higher as a poet than an engraver; he wrote idylls, romances, ballads, and dramas. He was usually called "Müller the Painter."

MÜLLER, GERHARD FRIEDRICH, a German traveller and historian, born in Herford, Westphalia, in 1705, died in Moscow in Oct. 1783. He studied at Leipsic, was recommended by Prof. Mencke, one of his teachers, to the Russian government, and filled various offices in the academy founded by Peter the Great. In 1780 he was appointed professor of history, and the same year made a tour through Germany, Holland, and England. In 1788 he accompanied the expedition of Gmelin and De Lisle to Siberia, and returned in Feb. 1748, having spent nearly 10 years in studying the geography and antiquities of that country. In 1747 he was appointed historiographer of the Russian empire, in 1754 secretary of the academy of sciences, in 1766 keeper of the archives at Moscow, and afterward was made councillor of state and invested with the order of Vladimir. The work by which he is best known is the "Collections for the History of Russia" (9 vols., 1782-'64). He also wrote a description of Siberia, an account of travels and discoveries made by the Russians, an essay on the origin of the Cossacks, and many other works. He has been called the father of Russian history. Müller wrote French, Latin, Russian, and German with equal ease.

MÜLLER, JOHANN GOTTHARD VON, a German engraver, born in Bernhausen, near Stuttgart, May 4, 1747, died in Stuttgart, March 14, 1830. He was educated as an engraver in Paris under Wille, and in 1802 was appointed professor of engraving in the academy of arts in Stuttgart. His prints do not exceed 33 in number. Among the best are the "Battle of Bunker Hill," after Trumbull's picture, Raphael's *Madonna della seggiola*, a St. Catharine with two angels after Leonardo da Vinci, and portraits of Louis XVI. and Schiller.—JOHANN FRIEDRICH WILHELM, son of the preceding, born in Stuttgart in 1782, died near Pirna, Saxony, May 3, 1816. After a careful art training under his father, he was sent to complete his studies in Paris, where in 1808 he executed the "St. John about to write the Revelation," after Domenichino, and "Adam and Eve under the Tree of Life," after Raphael. In 1809 he received a commission from Rittner, a print seller of Dresden, to engrave Raphael's famous *Madonna di San Sisto* in the Dresden gallery, which employed him during the remainder of his life. As the plate proceeded toward completion his interest in it seemed to increase; and finally, against the remonstrances of his friends, he gave himself up entirely to its execution, neglecting health and the ordinary duties of life. In 1814 he removed to Dresden and accepted a professorship of engraving in the academy there; but when the plate was completed the overtasked powers of the artist yielded suddenly with the cessation of his labors, and he expired a few weeks afterward, too late to see a finished proof of the engrav-

ing. It is one of the finest achievements of his art. Müller engraved only 18 plates.

MÜLLER, JOHANNES, a German physiologist, born in Coblenz, July 14, 1801, died in Berlin, April 28, 1858. He studied in the gymnasium of his native city until 1819, intending to become a priest in the Roman Catholic church. In that year he removed to the university of Bonn, where he conceived such an enthusiasm for the pursuit of science, that, following the example of Boerhaave and Cuvier, he abandoned his theological studies and determined to become a physician. At the age of 21 he took the degree of M.D., and went to Berlin to finish his studies and pass his state examination. Here, under the influence of Hegel and of Rudolphi, he was induced to reject the theory of Schelling, which "traced back all phenomena to the idea of the absolute," and with reference to which his previous studies had been conducted, and to recognize no system of physiology which is not founded upon a severe philosophical observation of nature. Returning to Bonn in 1824, he was appointed a *Privatdozent* or tutor in the university, in which capacity he lectured on general and comparative anatomy, physiology and embryology, general pathology and pathological anatomy, and at one time on the diseases of the eye and ear. His leisure hours were devoted to study and experiments, and he even attempted to a limited extent to practise medicine. Under such a multiplicity of pursuits his health gave way, but by the aid of the government he was enabled to restore it by travel and relaxation; and upon his return to Bonn in 1826 he was advanced to the rank of extraordinary professor of physiology and anatomy in the university, and in 1830 to that of professor. In 1833, a few months after the death of Rudolphi, although but 31 years of age, he was appointed to fill the chair of anatomy vacated by him at Berlin, and which was then considered the first in that department of science in Europe. In this position he remained until the close of his life, ranking among the first of living physiologists, and giving the direction to the study of medicine in Berlin and probably throughout Germany. To the effect of his publications may in a great measure be ascribed the recognition of medicine as one of the natural sciences. He generally passed his vacations in exploring the shores of the Mediterranean or other coasts of Europe, and became a great favorite with the people on the coast of Trieste, Nice, Messina, and other places, who called him the *illustrissimo professore Tedesco*. He barely escaped with his life in 1853, while travelling over the St. Gotthard, and again in 1855 in a voyage from Bergen to Hamburg, when from a collision one of his pupils, Wilhelm Schmidt, was lost with many others. Müller was a heavily built man of middle size, of great muscular strength, and strongly marked features. His benevolence was equal to the excessive modesty of his disposition; and although abrupt in his manners, he was genial

and affectionate. As early as 1825 his severe intellectual labors brought on a nervous fever, which also prostrated him in 1848; his anxiety in regard to the severe illness of his wife and one of his sons again impaired his health in 1857-'8; and he finally died from apoplexy. His remains were borne to the grave by 20 of his pupils, and the funeral was attended by the principal scientific, literary, and public men of the Prussian capital, including his friend Humboldt. His publications, numbering upward of 100, and of which a list of 87 is contained in the 8d volume of the *Bibliographia Zoologia et Geologia*, published in 1852 by the Ray society, embrace nearly every subject in comparative anatomy and physiology, not one of which has failed to receive new and valuable illustrations from his hand. Human physiology undoubtedly owes to his efforts its elevation from the position of a speculative to that of a positive science. His most important work is his "Manual of the Physiology of Man" (*Handbuch der Physiologie des Menschen*, 4th ed., 2 vols., Coblentz, 1851), containing his observations published in the journals and transactions of various European scientific bodies, and of which translations have appeared in France and England. Subsequent to 1834 he established and became a frequent contributor to the *Archiv für Anatomie, Physiologie und wissenschaftliche Medicin*, a periodical scientific publication containing an annual report of the progress of anatomical and physiological science. Among his other works are: *De Respiratione Fatus* (Leipsic, 1823), a prize dissertation; *Zur vergleichenden Physiologie des Gesichtsinnes des Menschen und der Thiere* (Leipsic, 1826); *Grundriss der Vorlesungen über die Physiologie* (Bonn, 1827); *Grundriss der Vorlesungen über allgemeine Pathologie* (Bonn, 1829); *Ueber die organischen Nerven der erectilen männlichen Geschlechtsorgane*, &c. (Berlin, 1836). He also wrote many dissertations on subjects not altogether physiological, including the structure and classification of animals, the organs of the senses in men and animals, &c. Among these are: *Horæ Ichthyologicae* (Berlin, 1849); *Ueber die phantastischen Gesichtsercheinungen* (Coblentz, 1826); *Der Tabak in geschichtlicher, botanischer, chemischer und medicinischer Hinsicht* (Berlin, 1832); *Ueber die fossilen Reste der Zeuglodonten*, &c. (Berlin, 1848); *Ueber Synapta digitata und über die Erzeugung von Schnecken in Holothuriën* (Berlin, 1852). His latest investigations were devoted to infusoria, and their results were published in the summer of 1860. He founded the *Zeitschrift für Physiologie und vergleichende anatomie*, which has been continued after his death by Dr. Peters, and was also a frequent contributor to a variety of other scientific publications. All the most prominent living physiologists of Germany have been formed in his school.

MÜLLER, JOHANNES VON, a Swiss historian, born in Schaffhausen, Jan. 3, 1752, died in Cassel, May 29, 1809. He was the son of a clergy-

man, and was originally destined for the church. He attempted to write a history of Schaffhausen at the age of 9. In 1769 he went to Göttingen, where he studied under Heyne, Walch, and Schlözer. On his return in 1772 he was appointed professor of Greek in the Schaffhausen gymnasium, and in the same year published a Latin work entitled *Bellum Cimbricum*. At this time he formed a close intimacy with Bonstetten, which gave rise to the "Letters of a Young Scholar to his Friend" (1802). Through Bonstetten's recommendation he became, in Feb. 1774, tutor in the family of Counsellor Tronchin of Geneva, and subsequently lived with the naturalist Bonnet. In 1778 he delivered a course of lectures on universal history, which were afterward published under the title of "Twenty-Four Books of Universal History," and translated into English. In the summer of 1779 he completed the first volume of his "History of Switzerland," which appeared at Bern in 1780 after several conflicts with the censors of the press. Soon afterward he went to Berlin, where he published his "Historic Essays." In May, 1781, he was appointed by the landgrave of Hesse to the chair of history at Cassel, and here produced his treatise "On the Influence of the Ancients upon the Moderns," and his "History of the Establishment of the Temporal Dominion of the Pope in the latter half of the 8th Century." He also published a work maintaining that the sacerdotal order was the defender of the liberties of the people against the arbitrary power of the temporal rulers, and this procured him many friends in Rome and in Catholic Germany. In 1788 he returned to Geneva; and in 1786, having been appointed court councillor and librarian at Mentz, he completed there the second volume of his "History of Switzerland." He was sent in 1787 as an envoy to Rome, and in 1791 was created a baron of the empire. When Mentz fell into the hands of the French in 1792 he went to Vienna, and was appointed a member of the privy chancery of the court and state. Here he published several political treatises, "Precipitation and the Peace of the Empire," "The Dangers of the Time," "The Safest Method of Obtaining Peace," and others urging the necessity of a close union and harmony among the German states. In 1800, having been appointed first keeper to the imperial library, he devoted himself with still more ardor to his great historical work. In 1804 he left Vienna and went to Berlin, where he wrote essays on Frederic the Great, on the ruin of the liberty of the ancients, and on ancient chronology. In 1806 he began a history of Frederic the Great, but was interrupted by the political disturbances which took place in consequence of the battle of Jena. Having been treated with marked attention by Napoleon, he was won over to his side, and expressed his admiration in so decided a manner in an oration on the glory of Frederic, delivered Jan. 29, 1807, that he became an object of suspicion in Prussia.

He therefore accepted a situation at the university of Tübingen, but on his way thither was appointed by Napoleon secretary of state to the new kingdom of Westphalia. The following year he exchanged this office for that of director of public instruction, and died not long after, having just finished his 5th volume of Swiss history. His complete works were published at Tübingen in 27 vols. (1810-'19). His great work, *Geschichte der Schweizerischen Eidgenossenschaft*, was brought down only to 1489. It is distinguished for its vast research, and for the attractiveness of its style, and places its author in the front rank of historians. Müller's letters to his friend Bonstetten contain much valuable information in regard to his times, and furnish materials for forming a correct estimate of his own character. His death was hastened by the melancholy into which his load of debt, the failure of his plans, and the condition of the times had plunged him.

MÜLLER, KARL OTFRIED, a German philologist and archaeologist, born in Brieg, Silesia, Aug. 28, 1797, died in Athens, Aug. 1, 1840. He was educated at the gymnasium of Brieg, the university of Breslau (at the latter institution devoting himself principally to the study of philology), and that of Berlin, where he was graduated in 1817, and published in the same year his *Ægineticorum Liber*. Upon leaving Berlin, he was appointed instructor in ancient languages in the Magdalenum of Breslau, where he employed much time in mythological studies and in the analysis of the different mythical cycles, the results of which were subsequently published in his important work on the history of Hellenic races and cities, *Geschichte Hellenischer Stämme und Städte*, of which the 1st volume, entitled *Orchomenos und die Minyer*, appeared at Breslau in 1820. In 1819 he received an invitation to fill a professorship in Göttingen, the duties of which included a series of lectures on archaeology and ancient art; and in order to prepare himself he visited France, England, and various parts of Germany. His work on the Dorians, *Die Dorier* (2 vols. 8vo., Breslau, 1824), forming the 2d and 3d volumes of his *Geschichte Hellenischer Stämme und Städte*, was intended to show the connection of manners, religion, politics, and history in one of the Greek races. An English translation by H. Tuffnell and Sir George Cornewall Lewis was published at Oxford in 1830, with additions and corrections furnished by the author, and a new German edition of the whole work has since appeared (3 vols., Breslau, 1844). In 1840 a new English edition of the "Dorians" was also published. A work on Attica, intended to form a continuation of this series, was projected by the author, but never undertaken. Among his remaining works, the most important are the *Prolegomena zu einer Wissenschaftlichen Mythologie* (Göttingen, 1825), of which an English translation by J. Leitch appeared in 1844 (8vo., London); a work on the early history of Macedonia, entitled

Ueber die Wohnsitze, die Abstammung und die ältere Geschichte des Makedonischen Volkes (Berlin, 1825); *Die Etrusker* (Breslau, 1828); and *Handbuch der Archæologie der Kunst* (4th ed., Bonn, translated by J. Leitch, London, 1850), the last being the first general treatise on the history of ancient art which appeared in Germany. He also undertook for the society for the diffusion of useful knowledge a history of Greek literature, of which only the 1st volume and a portion of the 2d were completed at his death. The work was published both in England and Germany, and has lately been completed by Prof. Donaldson (3 vols., London, 1856). He published also a number of special archaeological treatises and articles for the periodicals, and edited Festus, Varro's *De Lingua Latina*, and the *Eumenides* of Æschylus. In 1840 he undertook a tour through southern Italy and Greece, and while engaged at Delphi in superintending some excavations, was seized with a fever, the result of heat and fatigue, and died soon after being removed to Athens.—JULIUS, a German theologian, brother of the preceding, born in Brieg, April 10, 1801. He studied law at Breslau and Göttingen, and theology at Berlin, and in 1825 became pastor of Protestant congregations in Schönbrunn and Rosen in Prussia. In 1834 he was appointed assistant professor of theology in the university of Göttingen, in 1835 professor of dogmatic and moral philosophy in Marburg, and in 1839 titular professor of theology to the faculty of Halle. In 1850, in conjunction with Neander and Nitzsch, he established the "German Journal of Science and Christian Life," to which he furnished a series of articles on moral philosophy and ecclesiastical discipline. Among his publications are: *Das Christliche Leben, seine Kämpfe und seine Vollendung* (3d ed., Breslau, 1847); *Die Christliche Lehre von der Sünde* (3d ed., 1849; English translation, 2 vols. 8vo., Edinburgh, 1856); *Die erste Generalsynode der evangelischen Landeskirche* (Berlin, 1847), &c.

MÜLLER, OTTO, a German novelist, born in Schotten, June 1, 1818. After having completed his education at Darmstadt, he was employed for some time in the libraries of the grand duke and prince of Hesse-Darmstadt, edited for about 8 years, until 1843, the *Frankfurter Conversationsblatt*, a literary journal, and in 1848 joined the staff of the *Manheimer Journal*. After the death of his wife, Gustava Fritze, who had fallen in love with him on account of her admiration for his work on the poet Bürger, he removed to her native city Bremen (1852), but in 1854 returned to Frankfurt-on-the-Main, where he was engaged in the preparation of Meidinger's collection of novels (*Deutsche Bibliothek*), and in the foundation of a literary weekly journal (*Frankfurter Museum*). In 1856 he married a sister of his late wife, and has since taken up his residence in Stuttgart. His *Bürger, ein Deutsches Dichter-Leben* (Frankfurt, 1845) had been preceded by a

series of novels, and was followed by some political novels, as *Georg Volker, ein Roman aus dem Jahre 1848* (3 vols., Bremen, 1854), and by several other works, of which his *Charlotte Ackermann* (Frankfort, 1854) was most admired, and was translated into French by Porchat under the title of *Charlotte Ackermann, souvenirs du théâtre de Hambourg au XVIII^e siècle* (Paris, 1854). Among his recent works are *Der Stadtschultheiss von Frankfurt* (Stuttgart, 1856), and *Andrea del Castagno* (Frankfort, 1857); and he is now (1860) engaged upon a novel of commercial life.

MÜLLER, OTTO FREDERIK, a Danish naturalist, born in Copenhagen, March 1, 1780, died Dec. 26, 1784. He was of humble extraction, and was educated for the church. At 23 years of age, by his intelligence and uprightness, he recommended himself to the countess de Schulin, who engaged him as tutor to her son. His leisure hours were now devoted to the study of natural history; and upon his settling in Copenhagen in 1767, after a number of years of travel with his pupil, he was enabled to rank with the most eminent botanists and zoologists of the time. He soon after married a woman of fortune, and devoted the remainder of his life to scientific pursuits. His first important work, *Fauna Insectorum Friedrichsdaliana* (Leipsic, 1764), and *Flora Friedrichsdaliana* (Strasbourg, 1767), describing the insects and plants of the region of country in which he resided, recommended him to Frederic V. of Denmark, a munificent patron of science, by whom he was employed to continue the *Flora* of Denmark, undertaken in 1761 at the royal command by George Christian Oeder, who finished 3 volumes. To these Müller added 2 others, the last appearing in 1788. The study of zoology, and particularly of the minute animals, meanwhile began to occupy his attention almost exclusively, and in 1771 he produced a work in German on "Certain Worms inhabiting Fresh and Salt Water" (Copenhagen), which described many new species of those annulose animals called by Linnaeus *aphrodites* and *neridae*, and gave much additional information respecting their habits. His *Vermium Terrestrialium et Fluviatiliū seu Animalium Infusoriorum, Helminthecorum, et Testaceorum non Marinorum, succincta Historia* (2 vols. 4to., Copenhagen and Leipsic, 1773-4) is devoted to the infusoria, to observations on intestinal worms, and to the testaceous mollusca. The first of these he arranged for the first time into genera and species. His *Hydrachna in Aquis Danica Palustribus detecta et descripta* (Leipsic, 1781), and *Entomostraca* (crustaceans described by Linnaeus as *monoculi*, Leipsic, 1785), give the results of interesting investigations in the same field of research, and describe many species of minute animals previously unknown. To these was added an elaborate illustrated work on the infusoria, published in 1786, after his death. These 8 works, written in elegant Latin, are

models of literary composition, and, according to Cuvier, have given the author "a place in the first rank of those naturalists who have enriched science with original observations." His *Zoologica Danica*, which was intended to correspond, in the animal kingdom, with the *Flora Danica* in the vegetable, was commenced in 1779, but left incomplete, only 2 parts, each containing 40 plates, having been finished by him. These, however, are distinguished by great accuracy in the descriptions and figures of the animals described, and the work is of high value to the naturalist even at the present day. He wrote also a general catalogue of the animals of Denmark, entitled *Zoologica Danica Prodrōmus* (Copenhagen, 1777), and a variety of monographs on scientific subjects. He was a councillor of state and the recipient of other honorary appointments.

MÜLLER, PEDER ERASMUS, a Danish theologian and antiquary, born in Copenhagen, May 29, 1776, died Sept. 16, 1834. He was educated at the university of Copenhagen, where, after visiting France and England, he was appointed professor of theology in 1801. He was made bishop in 1822, and in 1880 appointed to the diocese of Seeland. Among his theological works are the "Christian Moral System" (1808), "Grounds for Belief in the Divinity of Christianity" (1810), and "Creeds of the Christian Church" (1817). His literary reputation, however, rests chiefly on his antiquarian writings, among which are essays "On the Importance of the Icelandic Language" (1818), and "On the Rise and Decline of Icelandic Historiography" (1818); a "Critical Examination of the traditional History of Denmark and Norway" (1828); and "Critical Examination of the last 7 Books of the History of Saxo Grammaticus." His greatest work is his "Library of the Sagas" (1816-18), in which he gives an account of all the Icelandic sagas or tales, their time of composition, their character, and their literary history. From 1805 to 1832 Müller was editor of the "Danish Literary Gazette," which, under the names of the *Nye Tidende af Laerde Sager*, *Laerde Efterretninger*, and *Dansk Litteratur Tidende*, lasted from 1724 to 1836. He also published a work on "Danish Synonymes" (1830), and began a critical edition of the Latin history of Denmark by Saxo Grammaticus, finished after his death by Velschön.

MÜLLER, WILHELM, a German author, born in Dessau, Oct. 7, 1794, died there, Oct. 1, 1827. In 1818 he joined the Prussian army as a volunteer, and in 1814 after the peace went to Berlin, and applied himself especially to the ancient German language and literature. From 1817 to 1819 he travelled in southern Germany and Italy, and on returning was appointed classical instructor in the newly organized school of Dessau for the training of teachers. His first work, *Blumenlese aus den Minnesängern* (1816), contained the fruits of his researches into early German poetry. In 1818 he published a translation of Marlowe's "Faustus," followed by

"Rome, Romans, and Roman Women" (1820), and "Poems from the Posthumous Papers of a Travelling Musician" (1822-'4). In 1821 the first of his "Songs of the Greeks" appeared, and in 1827 his "Lyrical Walks." He edited a "Library of the German Poets of the 17th Century," and wrote much for literary annuals. —FRIEDRICH MAX, a German orientalist, son of the preceding, born in Dessau, Dec. 6, 1823. He was educated at the university of Leipsic, where he devoted himself almost exclusively to the study of Sanscrit, and in 1845 repaired to Paris to procure materials for an edition of the *Rigveda* with the commentary of Sayanacarya. The work was published in England, whither he had gone for further materials, in 1849-'54 (3 vols.), at the expense of the East India company. In 1850 he was appointed deputy Taylorian professor of literary history and comparative grammar in the university of Oxford, and in 1851 an honorary member of the university. Since 1854 he has held the professorship of modern European languages in the same institution. Among his other works are translations of the *Hitopadesa* (Leipsic, 1844), and of Kalidasa's *Megha-Duta* (Königsberg, 1847); a treatise "On the Comparative Philology of the Indo-European Languages in its bearing on the Early Civilization of Mankind," which in 1849 gained the Volney prize; "The Languages of the Seat of War in the East" (London, 1854); "Buddhism and Buddhist Pilgrims" (1857); "History of Sanscrit Literature" (1859); and many important contributions to various English periodicals.

MULLER, WILLIAM JOHN, an English painter, born in Bristol in 1812, died there, Sept. 8, 1845. He was of German extraction, and his father was curator of the Bristol museum. He studied with J. B. Pyne, the landscape painter, and in 1838-'4 made an extensive tour through Germany, Switzerland, and Italy, bringing back numerous sketches of great excellence. His first pictures exhibited in the royal academy attracted little notice. In 1838-'9 he undertook a tour through Greece and Egypt, among the results of which were two powerful landscapes, "Athens from the Road to Marathon," and "Memnon, or Ruins at Gornou in Egypt at Sunset," both of which were badly hung at the academy exhibition, and were disposed of for less than a tenth of their present value. In 1843 he accompanied Sir Charles Fellows on his expedition in quest of the Xanthian marbles, and returned in the following year with numerous sketches. Five pictures of Asiatic scenery in the exhibition of 1845 were treated with not less neglect than his previous contributions, and soon after he was seized with severe illness, the result of mingled fatigue, anxiety, and mortification at these repeated slights, from which he never recovered. His pictures subsequently commanded high prices, and a collection of 800 sketches was sold soon after his death for £4,860. He was an occasional contributor to the "Art Journal," and

in 1841 produced a beautiful work entitled "Picturesque Sketches of the Age of Francis I."

MULLET, a name given to two families of acanthopterygian fishes, the *mugilida* and the *mulrida*, though the latter, to avoid confusion, are better styled surmullets. In the *mugilida*, the body is more or less cylindrical; head and body covered with large, easily detached scales, in reality ctenoid, but so slightly denticulated as to appear cycloid; gill covers thin and smooth; head flattened, and the eyes large and far apart; the mouth small, and the teeth, when present, exceedingly fine; a kind of crest in the lower jaw received into a groove in the upper; dorsals 2, small and distinct, the 1st with usually 4 spinous rays, the 2d with flexible rays; ventrals behind pectorals; the pharyngeals are very large, the stomach rather fleshy, and the intestine with a few pyloric caeca; the swimming bladder is large. More than 50 species of the principal genus *mugil* (Linn.) have been described, from Europe, America, Africa, and the East Indies, inhabiting salt water, in preference about the mouths of rivers which they can ascend or descend with the tide. The gray mullet of western European waters (*M. capito*, Cuv.) attains a length of from 1 to 2 feet; the color above is dusky gray tinged with blue, the sides and belly silvery with longitudinal parallel dusky lines; a dark spot at the base of the pectoral fin. They are highly esteemed as food, and are caught in nets, from which they attempt to escape by jumping over the edge. This species is common on the English coasts, never far from land, and ventures many miles inland with the tide; it is one of the species which thrive even in fresh water; the food consists of soft or decaying animal or vegetable substances; the spawning time is in midsummer. The thick-lipped mullet (*M. chelo*, Cuv.), inhabiting the same waters, is more gregarious than the last; the lips are large and fleshy, with ciliated edges, through which the teeth penetrate like so many hairs. The gray mullet of the Mediterranean (*M. cephalus*, Cuv.) may be known by the two adipose veils which half cover the eyes, by the long ridged scale at the base of the pectoral fins, and by the entire concealment of the maxillary bone when the mouth is shut; it attains a weight of 10 or 12 lbs., and is taken in nets in great quantities at the mouths of the rivers; the flesh is tender, delicate, and fine-flavored, and has been esteemed from ancient times; it is eaten fresh, salted, and smoked. Of the American species may be mentioned the striped mullet (*M. lineatus*, Mitch.), 6 or 8 inches long, purplish brown above, lighter on the sides with 10 or 12 dark brown longitudinal stripes, pupils black and irides yellowish white, and abdomen pearl gray—an excellent fish, ranging from New York southward, and appearing in the markets in early autumn; the white mullet (*M. albula*, Linn.), of a general whitish color, about 9 inches long—a plump, firm fish, appearing in July and August, and prized by epicures; and

the rock mullet (*M. petrosus*, Ouv.), like the last found from New York to the gulf of Mexico. The African and Asiatic species are generally greenish brown above, with golden and silvery reflections, and white below.—The other family of mullets, more properly called surmulletts (*mullidae*), have some affinities with the perch family in the position of the fins, but differ from them in the unarmed opercula and the slightly ctenoid character of the scales; the branchiostegal rays are 4; the scales are large and easily detached; the dorsals are 2, widely separated, and all the fins are moderate; body oblong, little compressed; profile nearly vertical; mouth small, and teeth feeble; gill opening wide; eyes large and at top of the head; in most species the lower jaw has 2 barbels at the symphysis. In the genus *mullus* (Linn.) there are no teeth in the upper jaw, but pavement-like ones on the vomer and lower jaw, and no air bladder. The red mullet (*M. surmuletus*, Linn.) is bright red above and on the sides, with 3 golden yellow longitudinal lines behind the pectorals, and rosy white below; it attains a length of 12 to 15 inches. It is found from the English coast southward, being more common to the south, and very abundant in the Mediterranean, where it feeds upon crustaceans and mollusks; it is less esteemed as food than the next species. The bearded mullet (*M. barbatus*, Linn.) has a more vertical profile and a deeper and more uniform red color; comparatively rare north of the English channel, it is most abundant in the Mediterranean; this is the *rouget* of the French. Of about the same size as the last, it is more highly esteemed as food, for its white, firm, well flavored, and easily digested flesh; the old Roman epicures paid immense prices for this fish, sometimes as much as \$200 or \$300 for a single specimen; they kept them alive in *vivaria*, and exhibited their brilliant colors, rendered more beautiful in the agonies of death, to their guests, that their eyes might be delighted by what would soon gratify their palates.—In America fish of the allied genus *upeneus* (Ouv.), with teeth in both jaws, are called mullets; most of these have a large air bladder. The *U. maculatus* (Bloch), with others, 6 or 8 inches long, is found in the gulf of Mexico, the West Indies, and South America; the color is red, with a few blackish spots; the flesh is not much prized.

MÜLLNER, AMADEUS GOTTFRIED ADOLF, a German dramatist, born in Langendorf, near Weissenfels, Oct. 18, 1774, died in the latter place, June 11, 1829. He practised for some time as a lawyer, and wrote on jurisprudence. Subsequently he devoted himself to literature, and is best known by his dramas *Der neunundzwanzigste Februar* and *Die Schuld*, which were among the most popular productions of the fatalistic dramatic school (*Schicksalstragödie*) which had been introduced on the German stage by Werner. Müllner's miscellaneous writings were published in 2 vols. (Stuttgart, 1824-'6), and his dramatic works in 7 vols. (Brunswick, 1828).

MULOCK, DINAH MARIA, an English authoress, born in Stoke-upon-Trent, Staffordshire, in 1826. In 1849 appeared her first novel, "The Ogilvies," a work written with great earnestness, and containing many subtle delineations of character and life-like scenes. It was followed by "Olive," which proved no less popular, the "Head of the Family," a fairy tale entitled "Alice Learmont," "Agatha's Husband," "Avillion and other Tales," and a variety of minor tales and books for young people. In 1856 appeared "John Halifax, Gentleman," her best production; and she has since written "A Life for a Life," "A Woman's Thoughts about Woman," and "Studies from Life." An edition of her fugitive poems was published in 1860. Her books have been regularly reprinted in the United States, where they are widely read and appreciated.

MULREADY, WILLIAM, a British artist, born in Ennis, Ireland, in 1786. He was admitted a student of the royal academy at 14 years of age. His first productions, both as regards size and subject, were on a somewhat grand scale; but he soon restricted himself to pictures of much humbler pretensions, and his "Rattle" (1808), "Roadside Inn" (1811), and "Punch" (1818) showed careful study from nature and a good idea of color. His "Idle Boys" (1815) procured his election as an associate of the academy, and within a few months he was admitted to full membership. Since the death of James Ward he has been the patriarch of that institution. His subsequent works, including "The Fight Interrupted" (1816), "Lending a Bite" (1819), "The Wolf and the Lamb" (1820), "The Convalescent" (1822), "The Origin of a Painter" (1826), "The Last In" (1835), "First Love" (1840), "The Ford" (1842), &c., exhibited a constantly increasing refinement in artistic excellence; and for luminous color, delicacy of finish and expression, accurate drawing, and the graphic manner in which they tell their story, they are among the best productions of the modern English school. Some of his latest works illustrate scenes from the "Vicar of Wakefield," for which in 1840 he prepared a series of 20 designs; and in 1849 he produced a successful picture of a kind the opposite to that in which he had gained his reputation, entitled "Women Bathing." In 1848 an exhibition of his works was formed at the society of arts. Choice specimens of his style are contained in the royal collection, and in the Vernon and Sheepshanks portions of the national gallery.

MULSO, HESTER. See CHAPONE.

MUMMY (Arab. *mumia*), a dead body preserved from putrefaction by embalming or other means. The custom of thus preserving the bodies of the dead has prevailed in several countries. Humboldt found mummies in Mexico, and in Peru the bodies of the incas were rudely embalmed and dried. The Guanches, or aboriginal inhabitants of the Canaries, removed the entrails of the dead, dried the corpse in the air, covered it with aromatic varnish, and,

wrapping it in goat skins, kept it in a wooden case. These mummies, of which thousands have been found, are light in weight, of a yellow color, and have a strong aromatic odor. But it was by the ancient Egyptians that the art and practice of embalming the dead were carried to the greatest extent and highest perfection. All the dead of Egypt were embalmed in some manner, partly, it is supposed, from religious motives, and partly for sanitary reasons. The notion formerly prevalent, that the Egyptians preserved the body in order to keep it in a fit state to receive the soul when it should have passed through its allotted transmigrations, is inconsistent with the facts that tombs were sometimes sold to later occupants, and that animals of all kinds were also embalmed. (See EMBALMING.) The origin of embalming among the Egyptians has been attributed to their first merely burying in the sand, impregnated with natron and other salts, which dried and preserved the body, which natural process they afterward imitated, drugs and bitumen being later improvements. Bitumen does not appear to have been generally used before the time of the 18th dynasty. From inspection of the Egyptian mummies it is evident that several modes of preparation were in use, some of which differ in many essential points. The intestines taken from the body were cleaned and embalmed in spices, and deposited in 4 vases, one of which contained the stomach and large intestines, the 2d the small intestines, the 3d the lungs and heart, and the 4th the gall bladder and the liver. Each of these vases bore on the cover the name and the image of a deity who was supposed to have special charge of the parts contained in it. These vases were sometimes made of costly alabaster, but generally of common limestone. They were placed in the tomb with the corpse; and so careful were the Egyptians to show respect to every thing that belonged to the human body, that even the sawdust of the floor on which the embalmers did their work was gathered into linen bags, which also were placed in the tomb. The mummies preserved by balsamic and astringent substances are either filled with a mixture of resin and aromatics, or with asphaltum and pure bitumen. When filled with resinous matter they are of an olive color, and the skin dry, flexible, and as if tanned. The features are preserved, and appear as during life; the teeth, hair, and eyebrows are well preserved. Mummies of this kind are light, dry, and easily broken. Some of them are gilt all over, others only on the head and feet. The mummies filled with bitumen are black; the skin hard and shining, and as if varnished; the features perfect; and the whole corpse dry, heavy, and difficult to break. Of the mummies preserved with natron and filled with asphaltum and resinous substances, the skin is hard and elastic, resembling parchment, and does not adhere to the bones; the countenance is little altered, but the hair falls off on being touched. All these kinds of mummies

were enveloped each in linen bandages, sometimes 1,000 yards in length; the body was then enclosed in a cartonnage or pasteboard case fitting closely, which was richly painted and gilded and adorned with beads and bugles; the cartonnage was covered with 8 or 4 cases ornamented in like manner; and the whole was then enclosed in a sarcophagus of wood or stone. The bodies of the poor, which were salted and boiled in bituminous matter, are the most numerous of all. They are black, dry, heavy, and very hard to break; neither the hair nor eyebrows are preserved, and there is no gilding upon them. It is singular that few mummies of children have been discovered in Egypt, though even those just born were embalmed. Embalming was practised by the Hebrews to some extent. Joseph commanded the physicians to embalm his father, and in the time of Christ it was "the manner of the Jews" to bury the body "wound in linen cloths with spices." The practice continued in Egypt till the 6th century, and was common among the Greeks there, and even among the early Christians. It seems to have fallen gradually into disuse. Mummies were formerly much used in medicine on account of the balsam they contain; but this employment of them has ceased.

MUMPS (*cynanche parotidea parotitis*), a specific inflammation of the parotid and submaxillary glands. This curious affection, called by the Scotch branks, and by the French *oreillons* or *ourles*, has been known from the time of Hippocrates. It commences with a feeling of pain and tension beneath the ear, swelling takes place, and motion of the jaw is painful. The swelling soon involves the parotid and submaxillary glands; it is somewhat pasty to the feel, and is unattended with redness of the skin. Sometimes one side only is affected, sometimes both at once, more commonly one after the other. The disease is attended with slight fever, but the pain is by no means proportioned to the swelling and the deformity. The duration of the complaint is from 8 to 10 days, it taking 4 days to attain its height, and 4 days being occupied by its decline. Occasionally in males the testes, and in females the breasts, become swollen and hard as the swelling of the salivary glands subsides; and very rarely, in the subsidence of the swelling either of the parotid or of the testes, inflammation of the brain or its membranes has occurred. The disease is often epidemic, and is generally believed to be contagious. It ordinarily requires little treatment, the administration of a laxative and warm and emollient applications to the affected part being all that is necessary. When the brain is attacked, it must be treated irrespective of the original affection.

MÛNOH, ERNST HERMANN JOSEPH VON, a German historian, born in Rheinfelden, Oct. 25, 1798, died there, June 9, 1841. He was for some time professor at Freiburg, and for many years he filled the chair of ecclesiastical history and law at Liège. From 1831 till his death

he officiated as director of the private library of the king of Württemberg. Among his principal works are: *Allgemeine Geschichte der neuesten Zeit* (6 vols., Leipzig, 1833-'5), and his autobiography, *Erinnerungen und Studien aus den ersten 37 Jahren eines Deutschen Gelehrten* (3 vols., Carlsruhe, 1836-'8).

MÜNCH-BELLINGHAUSEN, ELIGIUS FRANZ JOSEPH VON, baron, a German dramatist, known in literature by his pseudonyme of Friedrich Halm, born in Cracow, April 2, 1806. Various members of his family held high positions in the Austrian service. He early displayed much taste for dramatic literature. His *Grieldis* (Vienna, 1834) was received with much favor, and was succeeded by a series of other dramas, the most celebrated of which are his drama *Der Sohn der Wildnis* (1842; translated into English by Charles E. Anthon, New York, 1848, under the title of "The Son of the Wilderness," but frequently performed on the American stage under that of "Ingomar the Barbarian"), and *Der Fechter von Ravenna* (1854). Among his most recent works is a drama entitled *Iphigenie in Delphis*, in imitation of Goethe's *Iphigenie*, and a play written for the Schiller festival in 1859 entitled *Vor hundert Jahren*. He published a volume of poetry in 1850, and in 1852 a valuable work on ancient Spanish plays (Vienna, 1852), his position as director of the imperial library, which he has occupied since 1845, facilitating such bibliographical labors.

MÜNCHHAUSEN, GERLACH ADOLF VON, baron, a German statesman, born in Berlin, Oct. 14, 1688, died Nov. 26, 1770. He was descended from an ancient noble family: After having prosecuted his studies at the universities of Jena, Halle, and Utrecht, he held various judicial and diplomatic offices under the Hanoverian government. Soon after the foundation of the university of Göttingen, he was appointed its curator, and acted in this capacity for upward of 30 years. He established the library and other institutions connected with the university, which was chiefly indebted to him for its rapid development. He was appointed prime minister of Hanover in 1765.

MÜNCHHAUSEN, HIERONYMUS KARL FRIEDRICH VON, baron, a German soldier, born in 1720 on his paternal estate of Bodenwerder, Hanover, died there in 1797. He was descended from the so called white branch of the Münchhausen family, served in his youth as a cavalry officer in the Russian army, and passed his latter days in Hanover. He delighted in telling the most wonderful stories of his adventures in the campaign against the Turks in 1737-'9, which gained for him in Germany the reputation of one of the greatest living liars. The stories themselves were soon repeated from one end of the country to the other, and created then, as now, universal merriment. They are said to have been first compiled by Rudolf Erich Raspe, a man of letters, who, being compelled to flee from Cassel to England on account of a charge

of embezzlement, was engaged in London in literary pursuits, and is generally believed to have published anonymously an English edition of the stories under the title of "Baron Münchhausen's Narrative of his Marvellous Travels and Campaigns in Russia" (London, 1785). A 2d edition, considerably enlarged and ornamented with views from the baron's drawings, was published at Oxford in 1786, under the title of "The Singular Travels, Campaigns, Voyages, and Sporting Adventures of Baron Munnikhousen, commonly pronounced Münchhausen; as he relates them over a bottle when surrounded by his friends." A 3d edition, published by Kearsley in London the same year, bore the additional title of "Gulliver Revived," and was soon followed by others. The work was first issued in a German form in 1786, under the auspices of the poet Bürger, who remarks in a subsequent issue, in which he used the 5th English edition: "It is in truth somewhat singular to see the following tales, which were produced upon German soil and have wandered in various forms and dresses through their own country, at last collected and made known through the press abroad. Perhaps Germany in this instance, as in others, has not done justice to her own deserts. Perhaps the English know better what humor is, how valuable to the world and how honorable to its possessor. However this may be, we find ourselves, in spite of all the speculations of our own vigilant writers, obliged to import a native production from a foreign country." The last German edition of this famous work, entitled *Des Freiherrn von Münchhausen wunderbare Reisen und Abenteuer* (Göttingen and Berlin, 1849), contains an able introduction by Adolf Ellisen upon the life and writings of the author, the sources and originals of the Münchhausens, and the literature of fictitious travels in general. The tradition of the baron's story-telling is supported in the work by the evidence of a clergyman who lived much in his society, and who informed Mr. Ellisen's father, a medical man of Göttingen, who himself visited the baron in his latter days, that the old officer used to relate his most surprising adventures "in a cavalier manner, with a military emphasis, but without any passion and with the easy humor of a man of the world, as things which required no explanation or proof." But although the compiler of the work may have been in a great measure indebted to the narratives of the baron, a large proportion of the hunting stories are derived from Henry Bebel's *Facetis* (Strasbourg, 1508), while other incidents are borrowed from Castiglione's *Cortegiano* and Bildermann's *Utopia*, which are included in Lange's *Delicia Academica* (Heilbronn, 1765). A new and free German version of the English edition appeared in Leipzig in 1846, under the title of *Münchhausen's Lügenabenteuer*. The work still maintains its popularity in Germany as well as in England and the United States. Imitations of Münchhausen's stories are called

in Germany *Münchhausiaden*. The success of the work has called much attention to the elements of humor and poetry in the character of the class of people who listened most to Münchhausen's stories, and given rise to Immermann's celebrated *Münchhausen* (4 vols., 2 ed., Düsseldorf, 1841), and to Adolf Schrödter's picture representing the baron surrounded by his listeners.

MUNDAY, ANTHONY, an English dramatist, born in 1558, died in London, Aug. 10, 1633. After having been an apprentice and actor, he went to Italy, and became a student in the English Catholic college at Rome. On returning to England, he abjured his religion, appeared as a witness against some Catholic conspirators, and subsequently published a report of their execution, having held a disputation with one of them at the foot of the gallows. He next became a playwright, and especially devoted himself to the contrivance of city pageants. Mr. Collier enumerates 14 plays which were written either wholly or in part by Munday.

MUNDT, THEODOR, a German author, born in Potsdam, Sept. 19, 1808. He was educated in Berlin, spent some time in literary pursuits in Leipsic, and became prominent among the young Germany school of writers and politicians, of whom Heine and Börne were the principal exponents. His liberalism giving umbrage to the government, he travelled in various parts of Europe, and was permitted to teach at the university of Berlin after his return in 1839. In 1848 he was appointed professor of general literature and history at Breslau, and since 1850 he has officiated as director of the library of the Berlin university. Among his earliest writings was *Madonna, oder Unterhaltungen mit einer Heiligen* (Leipsic, 1835), which attracted much attention. Its morbid though poetical views of life are said to have prompted Charlotte Stieglitz to commit suicide from devotion to her husband, whom she hoped to divert from his varied troubles by the greater sorrow caused by her death. Mundt edited her writings under the title *Charlotte Stieglitz, ein Denkmal* (Berlin, 1835). Among his subsequent works are a series of novels, the best of which are *Thomas Münzer* (Altona, 1841), and *Carmola, oder die Wiedertaufe* (Hanover, 1844); *Mendoza, oder der Vater der Schelme* (Berlin, 1847); and *Die Matadore* (1850). He has also published *Spaziergänge und Weltgänge* (Altona, 1838-'40), *Völkerchau auf Reisen* (Stuttgart, 1840), and other sketches of travels, and a brilliant delineation of the character of Knebel in the edition of that author's posthumous works which he prepared in concert with Varnhagen von Ense. Among his more solid productions are *Kunst der Deutschen Prosa*; *Allgemeine Literatur-Geschichte*, in continuation of that of Schlegel; *Dramaturgie*; *Geschichte der Literatur der Gegenwart*, &c. His *Geschichte der Gesellschaft* (1844) was followed by a *Geschichte der Deutschen Stände* (1853); and he published in 1851

an interesting work on Macchiavelli. He began in 1844 the publication of an edition of Luther's political works. His *Rom und Neapel* was published in 1860.—KLARA, wife of the preceding, known under her pseudonyme of Luise Mühlbach, born Jan. 2, 1814, was married to Mundt in 1839. Her novels indicate the most unconventional views of life, ultra-liberal political opinions, and an unbridled imagination. Among them are *Gisela*, *Eva*, and *Die Tochter einer Kaiserinn*, the last an extravagant narrative of Russian despotism. Among her most recent works are *Friedrich der Grosse und sein Hof* (3 vols., Berlin, 1858), and *Berlin und Sanssouci* (4 vols., 1858).

MUNI or DANGER RIVER, a stream of western Africa, which rises in the Sierra del Crystal mountains and flows into Corisco bay in the gulf of Guinea, in lat. 1° 2' N., long. 9° 33' E. It is formed by 3 main branches, viz.: the Ntongo, 40 m. long; the Ntambounay, 70 m. long; and the Noya, whose length is about 80 m. These head streams have their sources in the Sierra del Crystal, and like the Muni itself follow a general westerly or south-westerly course. Their banks are thinly peopled by a variety of tribes.

MUNICH (Germ. *München*), a city of south Germany, capital of Bavaria, on the left bank of the Isar, in the midst of a plain upward of 1,600 feet above the level of the sea, 38 m. by railway from Augsburg, 325 m. from Frankfurt-on-the-Main, and 220 m. W. from Vienna; pop. in 1856, 137,095, including about 16,000 Protestants and 1,000 Jews, the rest being Roman Catholics. Since the beginning of the present century Munich has been so much enlarged and embellished, chiefly through the exertions of King Louis, that it is now one of the most interesting places in central Europe, vying in its attractions with the most renowned capitals of Germany, and surpassing them all in the splendor of some of its public buildings and works of art and in the vivacity of its population. The city consists of the old town, the numerous streets of which branch from the great market place, of 5 suburbs (the old St. Anna and Pfarr, and the new Schönhof, Maximilian, and Ludwig's Vorstadt), and of 8 suburbs or villages on the right bank of the Isar, the principal of which is that of Au. Beautiful streets and squares are found in the new parts of the city, but there are wide intervals between many of the houses, and the space over which they are scattered is capable of holding double the present population, so that the more modern and magnificent part of Munich has still a somewhat unfinished appearance. The most animated streets are in the old town. The Karlstrasse and Ludwigsstrasse are the most imposing thoroughfares of the new city. In the former are the Glyptothek, Pinakothek, and church of St. Boniface; in the latter, the university, the blind asylum, the new royal riding school, the new palace for the ministry of war, and various learned and public institu-

tions. The Max-Joseph's square, adorned with Rauch's statue of Maximilian Joseph, and facing the massive structure of the new royal palace, is the largest square of Munich. Among the other beautiful squares are the Odeon, Wittelsbacher, Karolinen, Maximilian, Karls, Königs, and Promenaden Platz, all more or less adorned with statuary. The most frequented public promenades are the royal park or Hofgarten, the Sonnenstrasse, and the English garden, originally laid out by Count Rumford and containing several fine works of art.—Munich is the seat of an archbishop, and contains upward of 20 Roman Catholic churches and chapels. St. Peter's, the oldest ecclesiastical edifice, dates from the 18th century. The cathedral (*Frauentirche*), completed at the end of the 15th, is a vast Gothic building, remarkable for its two lofty dome-capped towers. St. Michael's, or the Jesuits' church, is about 800 feet in length, and remarkable for the beauty of the interior and for the width of its roof, unsupported by pillars. The church of St. Cajetan contains the tombs of the royal family and Thorwaldsen's celebrated monument of Eugene de Beauharnais. Still more remarkable are the modern churches. The All Saints' chapel (*Allerheiligen-Hofkapelle*), built in the Byzantine or Lombard style after the designs of Klenze, was opened in 1837; it is embellished with marble, mosaics, painting, and gilding. The columns are of red Tyrolese marble with white bases and gilded capitals; the base of the walls is also of red marble. The upper part of the aisles is incrustated with different colored marbles. All the rest is covered with religious paintings in fresco upon a golden ground, executed by Hess and his pupils. The *Ludwigs-Kirche*, in the round arch style, is also famous for the beauty of its execution and its designs, and for the wealth of its decorations, which comprise colossal statues of St. Peter and St. Paul and other works by Schwanthaler, and Cornelius's great fresco painting of the "Last Judgment," upward of 60 feet high. The parish church of St. Maria Hilf in the suburb of Au, built by Ohlmüller between 1831 and 1839, in the German pointed style of the 14th century, with high lancet windows, contains 19 splendid painted windows illustrative of incidents in the life of the Holy Virgin, designed by the most eminent Munich artists and executed in the royal porcelain manufactory. The church or basilica of St. Boniface, attached to the Benedictine convent of the same name, built between 1835 and 1850 in the Byzantine style, is the largest and most splendid of them all. The front has a portico of 8 Corinthian columns with 8 bronze doors. The side façades have a double row of round-headed windows. The interior is divided into a nave 51 feet wide, and 70 double aisles, 15 feet wide and 40 feet high, supported on each side by 64 monolithic columns of marble disposed in 4 rows. The pavement is of marble mosaic, and the roof of open timber work, the beams of which are

carved and richly decorated, and the ceiling between them azure with golden stars. The walls are decorated with frescoes, the upper series commemorative of German saints and martyrs, and the lower series of the life of St. Boniface, executed by Heinrich Hess and his scholars. The small church of St. Salvador has been used for the Greek worship since the accession of King Otho to the throne of Greece; it has a service of plate presented by the late czar Nicholas. A beautiful place of worship for Protestants was opened in 1832, and a synagogue in 1826. Convents were suppressed at the beginning of the 19th century, but several of them were restored in 1829.—Prominent among the numerous charitable institutions of Munich are the general hospital (N. W. of the cemetery, which is one of the finest in Germany), and several other hospitals and orphan asylums, a lunatic asylum, children's asylums, &c. At the head of the educational institutions stands the university, which was removed from Landshut to Munich in 1826, and which in the first 6 months of 1860 had 1,092 matriculated students and upward of 70 professors. Its jubilee was celebrated with great pomp in 1859. The chair of chemistry has been occupied since 1852 by Liebig, who is also director of the chemical laboratory and (1860) president of the academy of sciences. The university has a library of 160,000 volumes, and attached to it are a number of schools for various branches of science, and the Georgianum, a Roman Catholic seminary. The city contains also 3 gymnasiums, 4 Latin schools, a normal school, a military academy, a young ladies' school and ladies' college (*Damenstift*), and a great number of other educational institutions, including academies of art, mining, military science, hydraulics, mechanical sciences (in the central polytechnic school), agriculture, commerce, and industry, and public common schools for Catholics, Protestants, and Jews. Under the late and present king, Munich has become the nucleus of a school of poets and of many scientific men. The names of Jacobi, Sömmering, Schelling, Oken, Görres, Fallmerayer, Ennemoser, Seuffert, Liebig, Thiersch, Neumann, and other eminent men have contributed to raise the intellectual importance of Munich. It possesses many scientific collections, the most interesting of which is the museum of natural history, which comprises the Brazilian collection formed by Martins and Spitz in their explorations of that country. In the same building are a cabinet of Greek and Roman coins and medals and a geological museum. There are also various literary associations in the city for historical and other scientific investigations. Among the many libraries, the magnificent public or royal library is the most extensive, having been enlarged by those of suppressed monasteries, and including now upward of 350,000 works in about 800,000 printed volumes, comprising 13,000 incunabula, about 50 xylographic publications, and nearly 19,000 MSS.—The fine

arts, however, constitute the chief glory of Munich. The academy of fine arts is divided into the sections of architecture, sculpture, painting, and lithography, the last named art having been invented in Munich by Aloys Senefelder, a native of Prague, at the close of the 18th century. It contains a museum of antiquities and casts, the Schwanthaler museum, and the studios of many artists. Peter von Hess, Heinrich Hess, and Kaulbach are residents of Munich. The famous Glyptothek or sculpture gallery was built by Klenze from 1816 to 1880, and contains collections of statuary from the earliest eras of art to the present time. It is divided into 12 halls. The 1st contains Egyptian and the 2d the earliest Greek and Etruscan antiquities. Most celebrated is the 3d hall, with the *Æginetan* marbles discovered in 1811 by Haller and the Englishmen Cockerell and Forster, and restored by Thorwaldsen. These sculptures are classed among the most valuable remains of antiquity, artistically as well as archæologically, from the connection which they show between the primitive practice of art to which they belong and its perfection in the period of Phidias. The 4th hall is called the hall of Apollo from the statue of that god in Parian marble ascribed to Ageladas, and formerly called the Barberini muse. The 5th hall (hall of Bacchus) contains the sleeping or Barberini fawn, and other famous works. The 6th hall (hall of the sons of Niobe) is remarkable for a kneeling figure of Ilioneus, the youngest son of Niobe. The subjects in the 7th hall (hall of the gods) illustrate heathen mythology, and those in the 8th (Trojan hall) the heroes of Homer. In the 9th, or hall of heroes, are statues of Alexander the Great and Nero; and the 10th, or Roman hall, is remarkable for its decoration, and contains a series of busts of emperors, which exhibit the decline of Roman art. The 11th is the hall of colored sculpture, and the 12th hall is devoted to modern statuary, including a copy of Canova's Paris and Venus, Thorwaldsen's Adonis and bust of King Louis, Schadow's "Girl fastening her Sandal," and other modern works. The colossal marble statues of Lorenzo Ghiberti and Donatello, respectively by Brugger and Von Lossow, were added to the Glyptothek by ex-King Louis in 1860.—The Pinakothek or picture gallery, a more extensive building than the Glyptothek, also designed by Klenze, of which the foundation was laid on Raphael's birthday, April 7, 1826, was completed in 1836. It contains about 1,800 paintings, consisting of the best works of the royal collections, arranged according to schools in 9 halls and 28 adjoining apartments or small cabinets in the 2d story of the building, the large works of each school being placed in the central hall, which communicates on one side with the apartments where the smaller paintings are placed and on the other with an extensive corridor, which is itself divided into 25 compartments or *loggias*, and adorned with frescoes by Cornelius illus-

trative of the history of the fine arts during the middle ages. Among the paintings are works of Cimabue, Giotto, Leonardo da Vinci, Correggio, Titian, and other Italian artists. The genius of Michel Angelo is illustrated in his capacity of painter, sculptor, and architect; and an entire compartment is filled with the works of Raphael. Albert Dürer, Rembrandt, Vandyke, and the other masters of the German, Flemish, and Dutch schools, are fully represented; and 95 works of Rubens take up the entire space of the central and largest hall of the gallery. There are also a few pictures by Murillo, Velasquez, Poussin, Claude, Vernet, and other artists of the Spanish and French schools. The lower story contains collections of 9,000 drawings by the old masters, including some of Raphael, Fra Bartolomeo, &c.; also the drawings of Cornelius for the *loggias*, and 3,000 drawings of South American scenery by Johann Lorenz Rugendas. The cabinet of engravings comprises about 800,000 works. On the ground floor of the W. wing is a collection of Etruscan and other vases. On the N. is the new Pinakothek designed by Voigt, begun in 1846 and completed in 1853, destined for the works of contemporary artists, and comprising 52 rooms in two stories. The upper floor, which contains them, is divided into 5 large central halls, 5 rooms on the south and 14 small cabinets on the north, beside a room at the west with Rottmann's encaustic paintings, views and illustrations of Grecian history and localities. In the central hall are Kaulbach's "Destruction of Jerusalem," and Schorn's "Deluge." It contains also Wilkie's "Reading of the Will." On the ground floor is the collection of paintings on porcelain, including copies of the most celebrated works of the picture gallery. A new building for the exhibition of works of art, designed by Ziebland in the Corinthian style, was opened in 1846. In the old picture gallery on the N. side of the royal park is a collection of antiquities and curiosities from different parts of the world. The Leuchtenberg gallery of paintings was removed to St. Petersburg in 1853. The new royal palace (*der neue Königsbau*), a magnificent and stupendous building, contains a large number of works of art. The interior presents an imitation of the ornaments of the *loggias* of the Vatican. The ground floor consists of state rooms painted in fresco by Schnorr, illustrative of the *Nibelungen*. The kings' and queens' apartments are adorned with paintings respectively from the Greek and German poets. The decorations of the throne room, drawing room, bedroom, writing room, and library of the queen are respectively devoted to Klopstock, Wieland, Goethe, Schiller, and Tieck. The most interesting part of the palace is the so called *Fest Saalbau*, containing on the E. side of the ball room two rooms for card playing called halls of the beauties, with portraits of beautiful women of modern times, including that of Lola Montez. The banquet hall, hall of Charlemagne, hall of Barbarossa, and hall of Rudolph

of Hapsburg are all decorated with choice works. The most stately of them all is the throne room. The Leuchtenberg palace in the Odeon square is a fine building. The new Wittelsbach palace in the Gothic style, begun in 1843 and completed in 1849, has been the residence of King Louis since his abdication. Among the other remarkable monuments of Munich is the Bavarian hall of fame, on the W. side of the Theresienwiese, consisting of a Doric portico forming 3 sides of a quadrangle, in the centre of which stands, on a pedestal of the height of 28½ feet, Schwanthaler's colossal statue of Bavaria, 61½ feet high, representing the protectress of Bavaria, accompanied by a lion. The busts of distinguished Bavarians are placed along the walls behind the 48 columns of the hall. In the tympana are 4 recumbent figures by Schwanthaler representing the 4 principal provinces of the kingdom. In the frieze are 92 metopas, all from designs of Schwanthaler. The triumphal arch (*Siegesthor*), at the N. end of the Ludwigsstrasse, is also a beautiful monument; and the foundation stone of a new arch in the old Doric style, to be called *Propylæen*, designed by Klenze, was laid in 1853 at the end of the Briennerstrasse. A corn hall (*Schrammenhaus*) was opened in 1853, and other new buildings are in progress. A new street (Maximilianstrasse) has also been recently formed with a view of the further enlargement of the city in the direction of the Isar.—The theatres and musical entertainments of Munich are among the best in Germany. Among the popular festivals is the annual agricultural meeting on the first Sunday in October (*October- or Volksfest*), which is held on the Theresienwiese, and lasts several days. The same place is used for horse races, &c.—The principal article of trade is grain, and two great fairs are held annually. The breweries of Munich enjoy a high reputation. The manufactures comprise woollen cloth, leather, silk, cotton, calicoes, tobacco, beet root sugar, pianofortes, playing cards, jewelry, bronze and iron works, coaches, and mathematical, surgical, optical, and astronomical instruments. Among the most celebrated industrial establishments are the royal bronze foundry; the bronze foundry of Stiglmeier; the royal painted glass and the royal porcelain manufactories; the establishment of Ettel, founded in 1815 by Reichenbach, for the manufacture of technological instruments; and Fraunhofer's manufactory of telescopes and optical instruments. Crawford's bronze statues of Beethoven and Washington and Quarenstroem's statue of Berzelius were cast in the royal foundry.—The name of Munich (*München*) occurs for the first time at the beginning of the 12th century. It became the residence of the dukes of the house of Wittelsbach, and was much enlarged after its destruction by fire in 1327, and endowed with many public buildings by William the Pious (1579-1626) and the elector Maximilian I. (1626-51). On May 17, 1632, it was taken

and held for some time by Gustavus Adolphus of Sweden. Under Charles Theodore (1777-'99) Munich was greatly improved and still further enlarged; and from an inferior town it has risen under the fostering care of King Maximilian I. (1799-1825), and particularly under that of his son Louis, to the rank of an important capital. While still crown prince Louis ordered the building of the Glyptothek and of other public works; and from his accession to the throne (1825) until his abdication (1848) he contributed most powerfully to invest Munich with its present splendor. Munich was entered by the French under Moreau, July 2, 1800, and on Oct. 12, 1806, by Napoleon, who again visited the city, Jan. 14, 1806, on occasion of the marriage of Eugène de Beauharnais. During the revolution of 1848 disturbances broke out in Munich, in consequence of which Lola Montez, who was supposed to exercise much influence over the king, was compelled to resort to flight, and the king himself abdicated, March 20, 1848, in favor of his son Maximilian II., who has since endeavored to imitate the example of his father in constantly enriching his capital with new treasures of art and learning. The railway to Vienna was opened Aug. 12, 1860.

MUNJEET, the root of an East India plant, *rubia munjista*, used for the same purposes as madder. The roots are of similar appearance as to size, &c., to those of madder, and are found in commerce in bundles of 2 or 3 feet in length. The coloring principle appears to be alizarine, and, as in madder, this is convertible into garancine, for which purpose the roots are used in Europe. Munjeet dyes a very bright scarlet.

MUNK, SALOMON, a French orientalist, of Jewish origin, born in Glogau, Prussian Silesia, in 1807. He was educated in Berlin and Bonn, and with the assistance of Michael Beer, brother of Meyerbeer, he was enabled to avail himself of the instruction of Sylvestre de Sacy and Ohézy in Paris. In 1835 he visited the university of Oxford, with a view of collecting materials for an edition in the original Arabic text in Hebrew letters of the celebrated work of Maimonides, *Moreh nebukhim* ("Guide of the Erring"), the publication of which he commenced in 1856, with a French translation and notes under the title of *Le guide des égarés*. In 1840 he was appointed deputy custodian of the oriental MSS. in the royal library of Paris. In the same year he accompanied Sir Moses Montefiore and M. Crémieux to the East on their mission in behalf of the persecuted Jews of Damascus, and secured in Egypt many interesting Arabic MSS. relating to the early literature of the Caraites and to other branches of eastern scholarship. On his return to Paris he devoted himself so assiduously to his learned researches that failing eyesight eventually compelled him to relinquish his office in the library, and he has lived in retirement since 1862. He wrote an exhaustive work on Palestine (*Palestine, description géographique, historique et archéologique* (Paris, 1845, included in Didot's collection

of the *Univers pittoresque*), and furnished many valuable dissertations to the *Encyclopédie des gens du monde*, and to the *Journal Asiatique*. A portion of his contributions to the *Dictionnaire des sciences philosophiques*, on Arabic and Hebrew philosophy, has been translated into German under the title of *Philosophie und philosophische Schriften der Juden* (Leipsic, 1852). In 1848 he published a paper to disprove the assertion of Sedillot, who had endeavored to deprive Tycho Brahe of the merit of the discovery of the variations of the moon, and to trace it to the Arabs in the 10th century. He has also written *Réflexions sur le culte des anciens Hébreux dans ses rapports avec les autres cultes de l'antiquité* (1838), and other works.

MUNKÁCS, a town of N. Hungary, county of Bereg, on the Latorcza; pop. about 5,000. E. of it, on a high rock, is situated the fortress of the same name, distinguished in Hungarian history by numerous sieges, and now used by the Austrians as a state prison. During the war of 1848-'9 the town and fortress were in the hands of the Hungarians. Among the renowned captives of Munkács was Ypsilante.

MÜNNICH, BURKHARD CHRISTOPH, count, a Russian soldier and statesman, born in the then Danish duchy of Oldenburg in 1683, died in St. Petersburg about 1767. He was the son of a peasant who was ennobled by Frederic III., king of Denmark, and early distinguished himself as a soldier. He was made a prisoner in the battle of Denain, and sent to Cambrai, where he was very kindly treated by Fénelon. In 1720 he was received with distinction by Peter the Great, to whom he had been introduced by Prince Eugene, and who confided to him the execution of the great canal of Ladoga. In the reign of Anna he became field marshal and president of the council of state. He besieged and conquered Dantzic in 1784, and was on his return employed in quelling disturbances in Warsaw. In 1785 he was called to the chief command of the army against the Turks, and gained great distinction by his triumphs over the enemy. He desolated the Crimea (1786), took Otchakov (1787), crossed the Dniester near Sinkowza (1789), defeated the Turks near Stevutchan, seized the fortress of Chocim, and occupied Moldavia. The treaty of Belgrade (Sept. 18, 1789) put an end to the war. Previous to the death of the empress he prevailed upon her to appoint the duke Ernest Biron of Courland as regent during the minority of her successor. But his hope of securing in this manner his own influence was disappointed by the duke taking the power into his own hands, upon which Münnich caused him to be arrested, and transferred the regency nominally to Princess Anna, the mother of Ivan, the young presumptive heir to the crown, while he assumed the reins of government as prime minister of the empire, endeavoring to consolidate his power by an alliance with Prus-

sia. The regent Anna lavished upon him her bounties, but entered into negotiation with Austria and Saxony in order to neutralize Münnich's coalition with Prussia, in consequence of which he relinquished his office (May, 1741). He was on the point of removing to Königsberg, when on the accession of Elizabeth to the throne (Dec. 1741) he was arrested by order of the empress and sentenced to death. The sentence was afterward commuted to exile to Siberia, but his estates were confiscated. He spent nearly 20 years in exile, raising vegetables for a livelihood, until 1762, when at the age of 79 he was recalled by Peter III., who restored to him his property and position. He enjoyed the friendship both of this sovereign and of Catharine II., who appointed him in the same year director-general of the Baltic ports. His *Ebauche pour donner une idée de la forme du gouvernement de l'empire de Russie* was published in Copenhagen in 1774.

MUÑOZ, FERNANDO, duke of Rianzares, husband of Maria Christina, queen dowager of Spain, born at Tarancon, province of Cuenca, in 1810. He was of very low birth, and while a private in the royal guards attracted by his personal beauty the attention and admiration of Maria Christina, to whom he was secretly married, Dec. 28, 1833, a few months after the death of her husband, King Ferdinand VII. His sister at the time was a washerwoman. The marriage was publicly solemnized, Oct. 13, 1844, and Muñoz was made duke of Rianzares, a Spanish grandee of the first class, and a knight of the golden fleece. On the occasion of the marriage of the duke de Montpensier to the sister of Queen Isabella II., Louis Philippe of France bestowed upon Muñoz the French title of duke of Montmorot.

MUNSELL, JOEL, an American printer, born in Northfield, Mass., April 14, 1808. He established himself in Albany in 1827, and was publisher and editor of the "New York State Mechanic" from 1841 to 1843. He has compiled "Annals of Albany" (10 vols. 12mo., Albany, 1850-'58); "Chronology of Paper and Paper Making" (1 vol. 8vo., Albany, 1857); and "Every Day Book of History and Chronology" (1 vol. 8vo., New York, 1858). He has also published "Historical Series" (7 vols.), in great part edited and annotated by himself, and "Woodworth's Reminiscences of the City of Troy;" and has at various times been the publisher of the "Unionist," "Albany Daily State Register," "Albany Morning Express," and "Statesman." Mr. Munsell has made the art of printing, in its history and application, a special study, and his collection of works on the subject, the largest ever made in America, has been in part purchased by the state for the New York state library. Beside the works enumerated, Mr. Munsell has contributed papers to the "Transactions" of the Albany institute.

MUNSTER (anc. *Mumhan*), the largest and southernmost of the four provinces of Ireland, bounded N. by Connaught, E. by Leinster, and

on other sides by the Atlantic, and comprised between lat. $51^{\circ} 26'$ and $53^{\circ} 12' N.$, and long. $6^{\circ} 56'$ and $10^{\circ} 30' W.$; length, 143 m.; breadth, 131 m.; area, 9,476 sq. m.; pop. in 1851, 1,857,243. The surface is much diversified. In the W. are the highest mountains in Ireland, and the S. is crossed by long chains of hills. About $\frac{1}{4}$ of the surface is arable, and $\frac{1}{4}$ actually under tillage. The principal rivers are the Blackwater, Suir, Lee, Bandon, Mague, Cashen, and Fergus, with the estuary of the Shannon, all of which are navigable. Except in the rugged uplands of Kerry, Clare, and western Cork, the limestone soil of Munster is of excellent quality. The climate is the most genial in Ireland. Geologically, the province is peculiar in Ireland for the rare appearance of igneous protrusions and the absence of bituminous coal, though possessing perhaps the most extensive anthracite deposit in the British isles. Clay slate is found, and copper abounds all along the S. coast. Lead, silver, iron, alum, black and mottled marbles, plastic clays, and fine ochres are found. The province is divided into the counties of Clare, Cork, Kerry, Limerick, Tipperary, and Waterford. As a kingdom of the Irish pentarchy, Munster was, perhaps, the most formidable of the 5 states; it early subjected Leinster to the payment of an annual tribute; its princes successfully opposed and ultimately expelled the Danes, and more than once usurped the sceptre of Tara as sovereigns of the entire island. It was then divided into 3 principalities, Thomond, Desmond, and Ormond (i. e., North, South, and East Munster), and Cashel was the civil, as it is still the ecclesiastical, metropolis. Till a recent date, the sovereigns of England governed the province through a local viceroy.

MÜNSTER, a city of Germany, capital of the Prussian province of Westphalia and of an administrative division of its own name, on the small river Aa, connected by railway with the principal cities of Europe, and with the river Ems by a navigable canal, about 80 m. N. N. E. from Cologne; pop. about 25,000. It is an ancient city with fine Gothic buildings, the ground floor of the houses of the main street being provided with arcades to support the upper stories. Among the public buildings are the cathedral and St. Lambert church, from the tower of which still hang the iron cages in which the bodies of John of Leyden and the other leaders of the Anabaptists were suspended after their execution in the great square. The house of John of Leyden still exists in the market place. The *Friedensaal*, or hall of peace, in the town hall, derives its name from the peace of Westphalia, which was signed there in 1648 and ended the 30 years' war. The Catholic university, which was supplanted in 1818 by the state university of Bonn, has been since reduced to a college of the theological and philosophical faculties. The manufactures consist of leather, woollen goods, cloth, linen, sugar, &c. Münster was known in the time of

Charlemagne under the name of Mimigardevord. In the 18th century it joined the league of the Hanse towns. The reformation was introduced there in 1532, and in 1535 and 1536 it witnessed the agitations of the Anabaptists. The former bishopric of Münster was raised in the 12th century to the rank of an imperial principality. In 1719 the archbishop of Cologne was invested with the see of Münster. In 1803 the bishopric was secularized, and a part of it ceded to Prussia, which constituted it a principality. This was by the treaty of Tilsit in 1807 ceded to France, but restored to Prussia in 1815, with the exception of a small district allotted to Oldenburg.

MÜNTER, BALTHASAR, a German clergyman and author, born in Lübeck, March 24, 1735, died in Copenhagen, Oct. 5, 1793. He studied theology at Jena, was for a time a preacher at Gotha, and became eventually celebrated as a pulpit orator in the German church of Copenhagen, and as the editor of the *Bekehrungs-Geschichte* of Count Struensee, whom he had attended on the scaffold (Copenhagen, 1772; English translation entitled "A faithful Narrative of the Conversion and Death of Count Struensee," &c., by the Rev. Mr. Wendeborn, 2d ed., London, 1774). He wrote a series of hymns (1778 and 1774). He was the father of the authoress Friederike Brun.—His son FRIEDRICH, born in Gotha, Oct. 14, 1761, died April 9, 1830, was educated in the universities of Copenhagen and Göttingen. He spent several years in Italy, and while in Rome caused a copy of the Coptic translation of the book of Daniel to be printed (1786), and discovered in the Corsini library the statute book of the templars, which he published in Berlin in 1794. From 1790 to 1808 he was professor of theology at the university of Copenhagen, and from that time till his death bishop of Seeland. He left various important historical and theological works.

MUNTJAC (*cervulus*, Blainv., or *stylocerus*, H. Smith), the name of several small East Indian deer, which seem to make the transition from the typical *cervidae* to the musk deer. The horns are small, with only one anterior snag, elevated on pedicels supported by longitudinal ridges on the face; there are large canines in the upper jaw, and large and deep suborbital pits; there are no metatarsal glands nor tufts; the hoofs are triangular, partly united in front by a web, and the false hoofs small and transverse; the hair is thin, shining, and generally unspotted, and the tail is tufted. The form is light and elegant; the few species inhabit the forests and jungles of elevated regions in India and its archipelago, where they are hunted by the natives and Europeans, usually with dogs, for the sake of their excellent venison. The common muntjac or kijang (*C. vaginalis*, Gray) is dark reddish brown, with the lower parts lighter, and a narrow white streak on the front edge of the thigh; it is about $2\frac{1}{2}$ feet high at the shoulders; in the living animal there are 2

folds of skin along the sides of the ridges which support the horns, uniting below like a V, but drying after death in 8 ribbed lines which suggested to Pennant the name of rib-faced deer. The principal horns are 4 or 5 inches long, at first straight, but curving inward and backward at the top, the anterior antler being about 1½ inches; the pedicels upon which they rest are 3 inches high, covered with skin and hair, so that when the antlers are shed they appear to have straight horns. The food consists chiefly of a kind of sugar cane, and malvaceous and succulent plants. Its speed and agility are great, the flight being generally in a circle; when brought to bay, it is capable of inflicting severe wounds upon the dogs with its canines; it is also taken in snares, and falls a frequent victim to beasts of prey. It is found in Sumatra and Java. The Nepaul muntjac (*O. moschatus*, Blainv.) is bright reddish yellow, the thigh streaked and under the tail white, and the chin and throat whitish. The Chinese muntjac (*O. Reevesii*, Gray) is grayish brown, with the hair short with paler rings; it has a larger head and tail than the common species, with less red and more bluish tinge, and no white over the hoofs. According to Gray, the earl of Derby had these 3 species at the Knowsley menagerie; but they so bred together that it became "impossible to discriminate the mules from the original species."

MÜNZER, THOMAS, a German religious and social revolutionist, born in Stolberg, Prussian Saxony, about 1490, beheaded in Mühlhausen, Thuringia, in 1525. Though in humble life, his parents were not poor, and he is said to have studied at Wittenberg and afterward at Leipsic, and to have been employed as a tutor in different towns. In 1519 he became chaplain of a nunnery near Leipsic, and in 1520 pastor of the principal church of Zwickau. His restless disposition and reformatory zeal led to quarrels with his colleagues, who were conservative followers of the reformation, and were supported by the aristocracy of the town, while Münzer aimed at social and political as well as ecclesiastical reforms, and exerted considerable influence upon the lower classes, particularly upon Nikolaus Storch, one of the numerous cloth weavers of Zwickau. Münzer and Storch became the leaders of a portion of the Anabaptists, who counted many adherents among the populace, and who afterward took part in the peasants' war. Münzer's agitation at Zwickau assumed such formidable proportions that he was compelled to leave the town at the end of April, 1521, after which he travelled as an itinerant preacher in different parts of Germany and Bohemia. At the beginning of 1522 he repaired to Wittenberg, where his disciples of Zwickau, the so called Zwickau prophets, had already begun to agitate the public mind. He put himself in relation with Melancthon and Bugenhagen, but his sympathies were with Carlstadt and other ultra-radical leaders; to their measures, however, Luther was so firmly opposed, that

Münzer was induced to take his departure. In April, 1523, he succeeded in obtaining a curacy at Allstädt. He introduced into the service a variety of innovations, circulated inflammatory writings in various parts of Germany, and founded a secret league, the principal object of which was to undermine the influence of the moderate reformers, and to revolutionize the country. In order to put an end to his proceedings, Luther appealed to the elector Frederic of Saxony, who repaired in the beginning of 1524 to Allstädt. Münzer delivered in the presence of the elector a sermon of the most revolutionary character, in consequence of which the publication of his writings was prohibited, and he was summoned to the seat of government. He persisted, however, in fomenting sedition. A Roman Catholic chapel in Malderbach was burned in June, 1524, at his instigation; and he called upon the populace to exterminate popery and to abolish the government by force of arms. After having been summoned for the second time before the authorities at Weimar (Aug. 1), he was expelled from Allstädt, and a few weeks afterward he betook himself to Mühlhausen, although Luther had cautioned the authorities against him. Conspicuous among the disciples who had preceded him there was Heinrich Pfeifer, a former friar, who now became the principal auxiliary of Münzer in his warfare against Luther. After spending some time in Nuremberg and Basel and in other parts of southern Germany and Switzerland, he returned to Mühlhausen in Dec. 1524. His influence there over the common people was so irresistible that many of the higher classes left the town, of which Münzer and Pfeifer became the sole rulers. The outbreak of the peasants' war in south Germany and Franconia became the signal of the most furious excesses on the part of Münzer and his followers. Under the influence of religious fanaticism and the love of plunder, the peasantry of the whole western portion of Thuringia rallied under Münzer's banner, destroying the mansions of the aristocracy and the houses of religious bodies, and only sparing the residences of those nobles who had joined their movement, and provided them with troops and arms. Mühlhausen was the head-quarters of this movement, which combined the religious Anabaptist with the social and political revolutionary element. But dissensions soon broke out between Münzer and Pfeifer, and the citizens of Frankenhäusen, which town was in the possession of the revolted peasants, opened negotiations with Count Albrecht of Mansfeld, who was supported in his operations by several German princes. A bloody battle was fought on May 15, which resulted in the total defeat of the peasants. Münzer fled in disguise to Frankenhäusen, but was captured and removed to the castle of Heldrungen. From that place he addressed a letter to the people of Mühlhausen (May 17), recommending his wife and

child to their care. After the capitulation of that town the principal ringleaders were sentenced to death, including Münzer and Pfeifer. Münzer was beheaded on the public market place. The holy sacrament was administered to him, according to the directions of Duke George, after the fashion of the Roman Catholic church.—See Melanchthon, *Die Historie von Thome Münzer* (1525); Strobel, *Leben, Schriften und Lehren Thomas Münzer's* (Nuremberg, 1795); Seidemann, *Thomas Münzer* (Dresden and Leipsic, 1842); and Heinrich Leo's essay on him in the *Evangelische Kirchenzeitung* (Berlin, 1856). Theodor Mundt has made the life of Münzer the basis of a historical novel, *Thomas Münzer* (3 vols., Altona, 1841).

MURAD. See AMURATH.

MURÆNA. See ERL, vol. vii. p. 24.

MURAT, JOACHIM, a French soldier, and king of Naples, born at La Bastide-Fortunière, near Cahors, March 25, 1771, executed in Calabria, Oct. 13, 1815. He was the son of an innkeeper, was educated for the church at the college of his native town, and afterward at Toulouse, and was ordained sub-deacon; but having been dismissed from the seminary on account of some youthful follies, he enlisted in a regiment of chasseurs. Cashiered for an outbreak of temper after he had risen through some of the lower grades, he became a waiter at a café in Paris. He soon entered the constitutional guard of Louis XVI., and on its dissolution received a sub-lieutenancy in a cavalry regiment, where he distinguished himself by soldierly efficiency and revolutionary spirit. He even wrote to the club of Jacobins declaring his intention of altering his name to Marat. For this indiscretion he was cashiered after Robespierre's overthrow on the 9th Thermidor, but at the end of a few months was restored to his rank as colonel, and on the 13th Vendémiaire served as aide-de-camp to Bonaparte. He accompanied the young general to Italy, where his heroism commanded universal admiration. After Beaulieu's defeat, he was sent to Paris to deliver to the directorial government 21 standards which had been taken from the Austrians, received a triumphal welcome in the metropolis, and returned to his post to share in the brilliant achievements that marked the latter part of 1796 and the campaign of 1797. He was still actively engaged in Italy, and had won the rank of brigadier-general, when he heard of the expedition to Egypt; he hastened to Toulon, and on May 10, 1798, embarked with Bonaparte for that country. Here he found an appropriate field for his skill as a cavalry officer, and made a deep impression even upon the Mamelukes. He was wounded at the taking of Alexandria and in the battle of the pyramids, and shone conspicuously in the Syrian campaign, contributing to the victory at Mount Tabor, April 16, 1799, and leading the assault at Acre. He did wonders in the battle of Aboukir, July 25, when he was again wounded, and was rewarded with the rank of general of division. He left Africa

with Bonaparte, who had conceived a strong liking for him, and in the *coup d'état* of the 18th Brumaire was at the head of the grenadiers who expelled the council of 500 from their hall at St. Cloud. The chief command of the consular guard and the hand of Caroline Bonaparte were his recompense. At Marengo he was at the head of the cavalry, and in 1801 commanded the army which invaded the kingdom of Naples and took possession of Elba. He was then appointed governor of the Cisalpine republic, and in 1804 of Paris. He was now made a member of the legislative body, and on the accession of Napoleon to empire received the baton of a marshal and the title of prince, and was made grand admiral and grand cross of the legion of honor. He had a large share in the success of the campaign of 1805 in Germany, where he led the cavalry, and was instrumental in the victory at Austerlitz. In 1806 he was made grand duke of Berg and Cleves. His abilities were strikingly displayed in the battles of Jena, Eylau, and Friedland, and still more in following up the results of these victories. In 1808 he was placed in command of the army which invaded Spain, where he gave evidence of generalship and good policy, and, in the secret hope of being made king of Spain by his brother-in-law, managed to secure considerable popularity among the Spaniards. After the elevation of Joseph Bonaparte to the Spanish throne he repaired to Italy, where, on Aug. 1, 1808, he was proclaimed king of the Two Sicilies, under the name of Joachim Napoleon. He attempted to ameliorate the condition of his new subjects, encouraged agriculture and industry, improved the public finances, increased the navy, and organized an army 70,000 strong. But unluckily he dreamed of vindicating the perfect independence of Naples, and, as a measure in this direction, ordered that all foreigners in his service should renounce allegiance to their native country. This imprudent edict, aimed especially at the French, called forth an imperial decree, declaring that, the kingdom of Naples being part of the French empire, every Frenchman should be of right a citizen of the Two Sicilies. The king was deeply wounded by this assertion of superiority, and listened to overtures from various European powers, particularly Austria. He durst not, however, disregard Napoleon's summons to take part in the campaign against Russia, and was, as usual, intrusted with the supreme command of the cavalry. At Borodino he heroically withstood the Russian fire during the whole day, and like Ney, his rival in bravery, came off untouched. But his energy seemed to falter when the retreat from Moscow commenced, especially after he had been worsted at Winkowo, Oct. 18, 1812. He however received the chief command of the army when, on Dec. 5, Napoleon left it in haste for Paris. But Murat proved unequal to his arduous task; he was anxious to return to Italy, and on Jan. 16, 1813, suddenly took his departure. Re-

pairing to his capital, he resumed his secret negotiations with the enemies of Napoleon; but his old affection overcoming his anger, he joined his brother-in-law in the campaign of 1813, and displayed his wonted intrepidity again at Dresden, Wachau, and Leipsic; but foreseeing the approaching fall of the emperor, he returned to Italy to look after his own interests. Here he was led astray by his wavering sentiments and political shortsightedness; he signed, Jan. 11, 1814, a treaty with Austria, by which his kingdom was guaranteed to him, on condition that he should act in concert with the allies at the head of an army of 30,000 men. He accordingly marched against Prince Eugène, viceroy of Italy, and forced him to retreat toward the Adige. But his new allies, having used him, were ready to abandon him, while the Bourbons were insisting on his overthrow at the congress of Vienna. On hearing of this, he sought the support of the Italian patriots, was secretly reconciled with Napoleon, and on the news of the latter's return from Elba marched against the Austrians. He was at first successful, advancing through the Papal States to the banks of the Po; but being worsted at Ferrara, he was forced to beat a hasty retreat; fought bravely, but ineffectually, for two days, May 2 and 3, at Tolentino (Ancona); was driven in disorder along the sea and across the Apennines, made an ineffectual stand at St. Germano and Mignano, and finally saw his army wasted away by battle and desertion. He now attempted negotiation; but, deserted by even his own emissaries, and the populace of Naples rising in insurrection, he was obliged to fly to Ischia, while his queen took refuge on board an English frigate. From Ischia he went to the shores of Provence, where he arrived on May 25 at night; his own country not offering him a safe refuge, he went to Piacenza, where he remained for two months, and then repaired to Bastia, where he landed Aug. 25. Here he prepared an expedition, not unlike that of Napoleon from Elba. On Sept. 28, at the head of 250 men, with 7 small transports, he set sail for Naples; his squadron was scattered by foul weather, while he himself with a few companions was driven to the gulf of St. Euphemia. He landed on Oct. 8 near Pizzo, attempted in vain to rouse the inhabitants of this village in his behalf, was pursued to the mountains by the peasants of the neighborhood, and fought to the last, but finally fell into the hands of his pursuers and was taken amid insults to the castle of Pizzo, where he was condemned to death by a court martial, and shot forthwith in one of the rooms of the castle. Being offered a chair and a handkerchief to bandage his eyes, he replied: "I have braved death long and often enough to face it with my eyes open and standing." Léonard Gallois published a *Histoire de Joachim Murat* (8vo., Paris, 1828); and the later events of his career have been chronicled by Coletta, *Les six derniers mois de la vie de Murat* (1821); and by Frances-

chetti, *Mémoires sur les événements qui ont précédé la mort de Joachim I.* (1826).—By his wife, Maria Annunziata Carolina, Murat left 2 sons and 2 daughters. Both the latter married Italian noblemen, Lætitia Josephine becoming Countess Pepoli, and Louise Julie Caroline, Countess Rasponi. The elder son, NAPOLEON ACHILLE, born Jan. 21, 1801, after his father's death repaired with his mother to Haimburg, Austria, came in 1821 to the United States, settled in Florida, married a grandniece of Washington, devoted himself to scientific pursuits, and wrote some essays upon the institutions of America. He died April 15, 1847, on his estate near Tallahassee. The younger, NAPOLEON LUCIEN CHARLES, born in Milan, May 16, 1803, after living near his mother until 1825, went to Spain, where he was arrested on suspicion. After his liberation he came to the United States, and married, his wife earning a support by teaching. On hearing of the events of 1848, he went to France, was welcomed by his father's old friends, and elected by the department of Lot to the constituent and the legislative assemblies. He was envoy extraordinary and minister plenipotentiary to Turin in 1849, became senator, Jan. 25, 1852, and received the title of prince of the imperial family. He is considered by some as a pretender to the crown of the Two Sicilies. He has one son, Joachim, who is an officer in the army, and one daughter.

MURATORI, LUDOVICO ANTONIO, an Italian scholar, born in Vignola, in the duchy of Modena, Oct. 21, 1672, died in Modena, Jan. 23, 1750. After completing his education at the university of Modena, he was ordained priest, and in 1694 was appointed keeper of the Ambrosian library at Milan, where he discovered several inedited Latin and Greek manuscripts, selections from which, with notes and commentaries, he published under the titles of *Anecdota Latina* and *Anecdota Græca*. In 1701 he became conservator of the public archives and principal librarian of Modena. His three great works in illustration of Italian history are *Rerum Italicarum Scriptores* (25 vols. fol., Milan, 1725-'51), *Antiquitates Italica Medii Ævi* (6 vols. fol., Milan, 1738-'42), and *Annali d'Italia* (12 vols., Milan, 1744-'9). To publish this vast collection several princes and nobles of Italy subscribed \$4,000 each. The best uniform edition of his works is that published at Venice (48 vols. 8vo., 1790-1810).

MURAVIEFF, an ancient noble Russian family originally settled in the former grand duchy of Moscow, and since the latter part of the 15th century in various other parts of the country. No other family in the whole Russian empire enjoys a greater reputation for intelligence, integrity, courage, decision, and activity, but likewise for undaunted pride, than that of Muravieff. Among its eminent members are: I. NICOLAI, who died in 1770, after having been director of the topographical bureau in St. Petersburg, lieutenant-general in the army, and governor of Livonia. He published in 1752 the first rudi-

mentary work on algebra in the Russian language. II. MIHAIL, born in Smolensk in 1757, died in 1807. He was tutor of the grand dukes Alexander and Constantine, for whose use he prepared a series of essays on history, ethics, and literature. Paul I. appointed him privy councillor, and Alexander I. deputy minister of popular instruction. An edition of his writings was prepared by Karamsin, and published in 3 vols. in Moscow in 1810, and a supplement in St. Petersburg in 1815. III. NICOLAI, son of the above mentioned Nicolai, born in Riga in 1768, died in Moscow in 1840. After having been for many years in active service in the Russian army and navy, he established near Moscow a private military academy, many of whose pupils afterward rose to distinction. He took a part in the campaign of 1812-'13, concluded the capitulation of Dresden with Gen. Dumas, and was present at the siege of Hamburg. After the peace he resumed his duties at his academy, which in 1816 was raised to the rank of an imperial institution. He conducted it till 1823, from which time till his death he devoted himself to agriculture. He was one of the founders of the Moscow agricultural society, and caused Thae's celebrated work on agriculture to be translated into Russian (1830). IV. NICOLAI, second son of the preceding, born in 1798. He entered the army in 1810, was promoted after a few years to the rank of captain in the general staff, was employed in the military service in the Caucasus, and published in 1822 an account of his travels in Khiva, to which country he had been sent on a political mission by Gen. Yermoloff. In 1828 and 1829 he took a distinguished part in the Persian war, and in 1831 in the Polish campaign, when he contributed much to the defeat of Gen. Sierakowski near Kazimierz, and to the removal of Gen. Dwernicki's army from the Polish territory. He was made lieutenant-general, commanded during the siege of Warsaw in September the right wing of the Russian army, and stormed the fortifications of Rakowiec. He commanded the Russian corps which landed in Asia, and arrested the advance of Ibrahim Pasha toward Constantinople after his victory at Konieh, and then visited Mehemet Ali in Cairo. Afterward he superintended the construction of the fortifications of Sebastopol, but fell into disgrace in 1856, for having in a sham fight made prisoners Nicholas I. and his staff, who commanded the part of the army opposed to Muravieff, and lived in retirement in Moscow as one of the leaders of the old Russian party until 1848, when he became a member of the board of war, and afterward commander of the corps of grenadiers in the Imperial guard. In 1855 he was placed at the head of the army of the Caucasus as general of infantry and governor of Transcaucasia, and distinguished himself in the eastern war by the siege of Kars, which he conducted with great energy and ability from the beginning of June till Nov. 27, 1855, when

the fortress was compelled to capitulate. The victory at Kars permitted the Russians to accede to terms of peace under less humiliating circumstances than at the time of the fall of Sebastopol. Muravieff was rewarded with the title of prince, but his haughtiness made him unpopular with his fellow officers and the court, and he has since lived in retirement in Russia, and travelled in southern Europe, although he still holds a seat in the council of the empire, with the rank of adjutant-general and general of infantry. V. MIHAIL, brother of the preceding, born in 1795. He founded in 1810 a mathematical society in Moscow, assisted his father in the military academy, and afterward officiated as governor of Grodno and Koorak. In 1842 he became chief director of the corps of surveyors and lieutenant-general, and in 1850 a member of the council of the empire. He is vice-president of the Russian geographical society, and has translated Garnier's *Géométrie analytique* into Russian. VI. ANDREI, the youngest brother of the preceding, has travelled extensively in the East and in Italy, and embodied his observations in a series of works which are highly esteemed. They are conceived in a religious and poetical spirit, treat of Syria and Palestine, of Rome, and of various sacred localities in Russia, and comprise about 20 volumes. He is also the author of several dramatic, theological, historical, and ecclesiastical works, including a history of Jerusalem, a biblical history, a history of the first 4 centuries of the Christian dispensation, a history of the Russian church which has passed through several editions, a history of Grusia and Armenia, &c.—Among the other prominent members of this family is Gen. MIHAIL MURAVIEFF II., who is a member of the government as president of the department of apanages, and was appointed in 1857 minister of the domains of the empire. He took an active part in the promulgation of the decree for the consideration of the abolition of serfdom (Jan. 15, 1858), and has since been actively employed in carrying that measure into practical effect. Lieut. Gen. MURAVIEFF III., another relative, is now (1860) governor-general of Eastern Siberia. He may be called the creator of the Amoor region. He concluded (May 24, 1858) the treaty by which China ceded to Russia the mouth of the Amoor and a large portion of the coast in Empress harbor, south of the river. He was created Count Amoorski, and it is his name which is so often mentioned in relation to China and Japan. Major-Gen. MURAVIEFF IV. was implicated in the movement of 1825, and exiled to the N. of European Russia, near the White sea. After the accession of Alexander II. he was pardoned and appointed civil and military governor of Nijni Novgorod. In this, one of the most important regions of the empire, he took a spirited part in enlightening the nobles on the question of the abolition of serfdom, and ranks among the foremost champions of that great measure.—A branch of the family has

adopted the name of Muravieff-Apostol, from the marriage of one of them in the 18th century with a daughter of a Cossack hetman named Apostol. Noticeable among this branch is IVAN (born in 1769, died in 1851), who translated Sheridan's "School for Scandal," Horace's "Satires," and Aristophanes's "Clouds" into Russian, and published in 1822 an account of his archaeological explorations in Taurida. He officiated as ambassador at several European courts, and was eventually made a privy councillor and senator. His son SERGEI was a conspicuous leader of the conspiracy against the government in 1825, and after the unsuccessful attempt in St. Petersburg he proclaimed the grand duke Constantine as emperor and took possession of the town of Vassilkov. He was defeated by the Russian troops near Ustinovka, Jan. 15, 1826; his brother Ippolit fell at his side, and he himself was severely wounded and removed to St. Petersburg, where he was executed July 25, 1826. Another brother was sentenced to 20 years' banishment to Siberia.

MURCHISON, SIR RODERICK IMPEY, a British geologist, born in Taradale, Ross-shire, Scotland, Feb. 19, 1792. He was educated in the grammar school of Durham, whence at the age of 18 he went to the military college of Marlow. Leaving this institution in 1807, he received a commission in the 86th regiment of foot, and, after a brief course of study at the university of Edinburgh, embarked in the spring of 1808 with the army under Sir Arthur Wellesley for Portugal. He participated in the battle of Vimiera, the retreat under Sir John Moore, and the battle of Corunna; served on the staff of his uncle Sir Alexander Mackenzie in Sicily, and at the siege of Cadiz; and, after reaching the rank of captain in the 9th dragoons, was in 1815 married, and retired from the service. For several years he occupied himself with foreign travel or with field sports, and about 1822, partly at the suggestion of his wife, and partly at that of Sir Humphry Davy, the latter of whom he occasionally accompanied on angling excursions, he determined to devote himself to scientific pursuits. Between 1822 and 1824 he attended the lectures of the royal institution, was afterward instructed in chemistry by Richard Phillips, and, selecting geology as his speciality, was in 1825 elected a fellow of the geological, and in 1826 of the royal society. His first scientific paper, a geological sketch of certain parts of Sussex, Hampshire, and Surrey, appeared in the "Transactions" of the geological society for 1826; and during the two succeeding years he made investigations in the oolite and old red sandstone formations of Scotland, the results of which were given to the public through the same channel. In 1828, in company with Sir Charles Lyell, he made a geological tour through northern Italy and the Auvergne district of France, 3 memoirs on which, their joint production, were subsequently published. In 1828-'30 he explored the eastern Alps, part of the time in company

with Prof. Sedgwick, and in conjunction with him published a memoir on the subject, illustrated by a geological map. Returning in 1830 to England, he commenced a systematic examination of the older sedimentary deposits of England and Wales, his object being to trace the history of the primeval rocks, and the "slow growth and development of nature from the first sediment of mud, sand, and pebbles cast by the accidents and revolutions of unfathomable ages over the fundamental, ancient gneiss, which contains no vestiges of vegetable or animal life." For upward of 7 years he was employed in investigations connected with this subject in western England and Wales, making from time to time announcements of his progress in the scientific journals; and in 1838 he combined the results of his observations in a 4to. volume of 800 pages entitled "The Silurian System," so called from the Silures, an ancient tribe inhabiting that part of the island of Britain in which his labors had been conducted, and in which the system of rocks studied by him is best developed. This work, treating chiefly of those early formations in which the first signs of life begin to occur, first satisfactorily described the relations of various deposits more ancient than the old red sandstone, and to which the name graywacke had been somewhat loosely applied. The system was divided into an upper silurian, consisting of Ludlow and Wenlock rocks, and a lower silurian, of Caradoc and Llandeilo rocks; and through regularly defined periods and by progressive stages, the march of animal life from the simplest invertebrate types to the higher orders of mammalia was distinctly traced. The deposits through which the silurian creatures were diffused were estimated to exceed 80,000 feet of perpendicular thickness, and their formation to have occupied the longest period in the history of the globe. Anxious to trace the silurian system through other parts of Europe, Murchison in 1835, and again in 1839, made excursions into the Rhenish provinces, and in 1840, in company with M. de Verneuil, visited northern and central Russia. In the same year the two geologists were invited by the emperor Nicholas to undertake a geological survey of Russia, with which they occupied themselves during 1841 and 1842, carefully exploring the Ural mountains and the southern provinces of the empire. Between 1842 and 1845 Murchison visited alone many portions of eastern and northern Europe, including Poland, the Carpathian range, and the palæozoic rocks of Scandinavia; and in 1845, in conjunction with M. de Verneuil and Count von Keyserling, he published an elaborate work on "The Geology of Russia in Europe and the Ural Mountains," in 2 vols. 4to., the 1st relating to the geology and the 2d (in French) to the palæontology of the subject, with copious maps and illustrations. For these services he was made a knight of the Russian order of St. Anne, and received from the emperor the grand

cross of the order of St. Stanislas; and in 1846 he was permitted by royal license to wear these orders in England, where he was also knighted. In 1849 the "Geology of Russia" was published in the language of that country, and in the same year the royal society of London rewarded the author of the silurian system with the Copley medal. Sir Roderick's next important contribution to geological science was his "Siluria: the History of the oldest known Rocks containing Organic Remains, with a brief Sketch of the Distribution of Gold over the Earth" (8vo., 1854), in which the existence of the silurian as an independent system, in many parts of both hemispheres, is conclusively established. It contains also an exposition of the author's views of geological theory, and a verification of an opinion previously expressed by him, that those portions of the so called cambrian, or system underlying the silurian, which contain fossils, are merely geographical extensions of the lower silurian deposits. In 1859 appeared the 3d edition of "Siluria," including the "Silurian System," in which are embodied the results of further explorations among the lower palæozoic formations. Among the important discoveries evolved by him is the existence of two distinct gneissic masses in the north of Scotland, which has rendered necessary the preparation of an entirely new geological map of that part of the country. This he has produced in his "New Geological Map of the Highlands," published in the "Quarterly Journal of the Geological Society" (May, 1860). "The new light which has thus been thrown on the history of the geological series of Scotland," says a recent writer, "showing that great masses of crystalline rocks, called primary, and supposed to be much more ancient than the silurian system, are here simply metamorphosed strata of that age, may with justice be looked upon as one of the most valuable results which have been attained by British geologists for many years. It was more especially on this ground that the royal society of Edinburgh deemed it proper to award to the founder of the silurian system the first Brisbane medal, with an address expressing their interest in and admiration for his recent researches in the highlands of Scotland." ("Edinburgh Review," July, 1860.) In Sept. 1860, he finished an extensive survey of the geological structure of the Scottish highlands, the results of which confirm the views embodied in his map above referred to. Not less unremitting have been the efforts of Sir Roderick and his followers to trace the thickness of the silurian strata in various parts of the British isles and the adjoining continent. The superincumbent devonian group bears an almost equal impress of his labors; and the permian system, so named by him from its extensive development in the Uralian province of Perm in Russia, which rests upon the carboniferous group of the great palæozoic division, forming the uppermost series of the lat-

ter, has been re-examined by him both in Russia and Great Britain, and its character clearly defined. "The succession of life from the lower to the higher forms of existence is the grand principle which he traces in all the geological records of nature; but in a very different sense from that which has recently been brought forward by Mr. Darwin. Sir R. Murchison finds in the great geological periods which he has described the clearest evidence, not of an unbroken series of spontaneous development by a process of 'natural selection, or otherwise,' but of distinct species called successively into existence and adapted to the existing conditions of the globe." (*Op. cit.*) Among the most useful of the investigations of Sir Roderick Murchison are those connected with the discovery of the gold fields of Australia, in which he was greatly aided by his previous observations of the geological position and age of the gold veins in the Ural mountains. He had early surmised that the original site of the principal gold masses was in the silurian rocks; and upon comparing specimens brought from Australia in 1844 by Count Strzelecki with Uralian rocks of the same character, he did not hesitate to predict the existence of gold in that part of the world. He subsequently endeavored, though without success, to draw the attention of government to the subject. In his discourse before the geographical society in 1852 he enunciated, from Bain's geological map of Cape Colony and a few other data, a hypothesis of the configuration of the African continent, which was entirely confirmed by the explorations of Dr. Livingstone in 1853-'6. Of the remaining works of Sir Roderick, the principal are: "Outline of the Geology of the Neighborhood of Cheltenham" (8vo., Cheltenham, 1834); memoirs "On the Geological Structure of the Alps, Apennines, and Carpathians," published after a 6th visit to the Alps; on the "Permian System," "On the Geological System of the North of Scotland," &c., contributed to the "Transactions of the British Association," and the "Quarterly Journal of the Geological Society;" and upward of 100 other papers published subsequent to 1825 in the scientific periodicals of Great Britain. In 1831 and 1832, and again in 1842 and 1843, he was president of the geological society; and in 1845, 1846, 1852, and 1856 he occupied a similar position in the royal geographical society. He took an active part in founding the "British Association for the Advancement of Science," of which he was elected the presiding officer at the Southampton meeting in 1846; and in 1851 he succeeded in establishing the new section of physical geography, ethnology, and philology. In 1855, in accordance with the request of the leading geologists and scientific men of Great Britain, he was appointed to succeed Sir Henry De La Beche as director-general of the geological survey of the United Kingdom, a position which he still holds. He is also director of the metropolitan school of science applied

to mining and the arts, and a member of the principal scientific bodies of Europe.

MURCIA, an ancient province or kingdom of Spain, bounded N. W. and N. by New Castile, N. E. and E. by the province of Valencia and the Mediterranean, S. E. and S. by the Mediterranean and Granada, and W. by Andalusia; area, 7,877 sq. m. The coast from the confines of Granada to Carthage is rocky and precipitous, but eastward from that port it is in general low and sandy. The surface is mostly mountainous. The principal ranges are the Sierra de Sagra, which nearly bisects the province from N. E. to S. W., the Sierra de Alcaraz, and the Sierra de Segura. The chief rivers are the Segura, Mundo, Moratara, and Sangonera. Where it can be irrigated the soil is often of exuberant fertility. Lead, silver, sulphur, and nitre are found. Murcia was conquered by the Moors in 712, and made a dependency of the caliphate of Cordova. In 1239 Mohammed Ali or Hudiel made it an independent kingdom, but in the following year it was united to Castile. It was divided in 1833 into the provinces of Murcia and Albaceta.—The modern Murcia comprises the southern part of the ancient province, bounded S. E. by the Mediterranean and drained by the river Segura and its tributaries; pop. in 1857, 387,877. The S. and N. W. portions are mountainous, and much of the soil is sterile, but near the rivers there are some rich tracts of land whose prolific vegetation has acquired for them the name of *huertas* or gardens. In the S. E. are mines of lead and silver.—MURCIA, the capital of the ancient and modern province, stands on the N. bank of the Segura, 280 m. S. E. from Madrid; pop. 55,058. It is situated near the centre of the beautiful valley called Huerta de Murcia, and was formerly fortified. The cathedral tower is a very imposing structure, consisting of 3 quadrangular stages, each diminishing perimetrically and crowned with a dome. It is ascended to the top of the first stage by an inclined plane 320 paces in length, and of gradually increasing steepness. From the first stage a narrow stairway of 210 steps leads to the summit of the tower, whence the view over the Huerta is truly magnificent. The chief manufactures are earthenware, leather, coarse linen, silk thread, silks and baskets, mats, cordage, and sandals made of the esparto rush. Murcia was founded by the Moors, and during their supremacy was one of the 7 metropolitan cities of Spain. It was captured by the Spaniards under Don Alfonso in 1240, and plundered by the French under Sebastiani in 1810.

MURDER. The extreme difficulty of finding words which define precisely a complex idea, is well illustrated by the existing uncertainty, so far as mere definition goes, as to what constitutes murder; although the crime is almost, if not quite, the highest known to the law, and the necessity for determining whether the charge is properly made, or fully sustained, is frequently occurring. Originally the word

meant only the secret killing of another. But the meaning of the word was extended more widely even in ancient times; and Coke gave a definition (3 Inst. 47) which Blackstone a century ago adopted, and which we think the best we know of. He says it is murder, "when a person of sound memory and discretion unlawfully killeth any reasonable creature in being, and under the king's peace, with malice aforethought, either express or implied." In previous articles on homicide and on manslaughter we have already had occasion to say that this element of "malice aforethought" is of the essence of murder. The greatest difficulty in determining whether a homicide be murder, is generally connected with the question of malice. It is quite certain that the malice need not be malice against the individual killed; for if one maliciously shoots at a person with intent to kill him, and missing him kills another, it is quite as much murder as if he had executed his intention. Nor indeed need it be directed against any person in particular. If one shoots into a crowd without knowing a person there, and kills one of them, it is murder; for such a criminal is regarded as having malice against the world, or, in the words of the old cases, he is *hostis humani generis*. Still there must be malice; for probably no kind or degree of mere carelessness or negligence would make a case of homicide one of murder. So if the death were caused by mere mistake, whether of law, of fact, or of the person, it would not be murder, unless it would have been murder if the law or fact or person had been what they were supposed to be. The principal exception to the necessity of proof of actual malice would seem to be where the death was caused without intention, but by the commission of and in attempting a felony. This distinction is so nice, that while, if one shooting at his neighbor's fowls with intent to destroy them shoots him by accident, this would not be murder, yet shooting them with intent to steal, and with the same result, would, it is said, be murder. Drunkenness has been considered in reference to manslaughter, and a somewhat similar rule is held as to murder; that is, intoxication, if it negatives the supposition of malice, would prevent the crime from being murder, unless it was a state of temporary insanity, purposely brought on that under it murder might be committed safely, in which case it would not be regarded as any excuse whatever.—Cases of compulsion have been somewhat considered; and it has been generally held that strict and actual compulsion was an excuse, but nothing less. If a captive on board a pirate were compelled to act with the crew in committing murder by threats of immediate death, this compulsion would undoubtedly be a sufficient excuse; but nothing less than a compulsion of this character would have this effect; as no command from a master, and no threat of a whipping, would be any excuse at all for a servant. But a jury, who are now

judges of the law as well as the fact in criminal cases, if they were satisfied, from the evidence of command or threat, of the absence of all malice, either general or individual, would seldom render a verdict of murder. So if a crime be committed by a wife in presence of her husband, it is presumed by the law that she did the act under his coercion, and she is not herself guilty. But murder and treason are exceptions to this rule; and here it is said that no proof of actual constraint by the husband operates as an excuse. Here also we should say, that if this constraint, as a matter of fact, disproved malice, there could be no verdict of murder. It seems quite well settled, as a general rule, that if many are confederate in any unlawful act, and some one of them, in doing the act, commits a murder, all are guilty; as if several conspire to seize a vessel forcibly and run away with her, and one opposing them is killed in the conflict, all are guilty of murder, in law, who are present, aiding and abetting in the unlawful act. And yet here also, in practice, we apprehend that it would be difficult to obtain a verdict of murder against any one not shown to have been the actual killer, and even against him unless some malice and intent could be shown. It is quite certain that no consent or even request of the party killed is any excuse whatever. At common law, counselling of suicide, if it causes the suicide, is murder. So if two persons agree to commit suicide together and use means which take effect only on one, it is murder in the survivor, provided he were present when the act was committed, as otherwise he is only an accessory before the fact. In Massachusetts two persons were in adjoining cells, and one advised the other, who was to be hanged the next day, to "hang himself and disappoint the people;" and the party advised did thereupon kill himself, and the adviser was held by the court to be guilty of murder; but the jury brought in a verdict of not guilty. Now, however, we think that the crime would generally be regarded as manslaughter. If one, by working on the fears of another, or by mere unkind usage, put one into "a passion of grief or fear" whereof he or she, being perhaps at the time in feeble health, dies, this, says Hale, though murder or manslaughter in the sight of God, is not so at common law. Most later writers have adopted this view, which is said to be in accordance with the codes of France and of Scotland; while in some countries the law is held to be, as an English judge in a recent case declared it to be in England, that one is guilty if he cause death by force "applied either to the body or the mind." We consider Hale's view as being that of the common law, and of the prevailing law of the United States. It was a rule of the common law, that it was murder to procure the conviction and execution of an innocent person charged with a capital crime by perjury. Now, however, we are satisfied that both in England and in the United States such a crime would

be punished only as an aggravated case of perjury, and not even as manslaughter.—The question has arisen, whether one can be indicted in a state or country for murder, if the criminal did actually in that state give the fatal blow, or fire the fatal shot, but the injured party went into another state or country and died there. The weight of authority, and we think of reason, is that no such indictment can be maintained. No country can punish a crime committed abroad, or partially abroad, unless by its own municipal provisions, applied to its own citizens. In accordance with this view, the statute of the United States against "murder on the high seas" has been held inapplicable to a case where a fatal blow was given with malice on the high seas, but the wounded person reached the shore and died on land.—An important question has exercised the courts, both of England and the United States, in respect to the evidence of murder and the burden of proof. It is a familiar principle that the burden of proof lies on the party who has a case to make out. But it is an equally familiar principle that this burden may shift in the course of the trial. Thus, A sues B on his promissory note, and the burden is on him to produce the note, and prove the handwriting; but if he does this, and the defendant says there was no consideration, or that he has paid the note, or rests on any other defence, the burden of proof shifts and is now on the defendant to prove the facts of his defence. Something like this was certainly the common law rule in a case of murder. If the government proved the death alleged, and that this death was caused by the prisoner, the burden of proof then shifted, and it lay on the prisoner to prove want of malice, or accident, or self-defence, or any other defence. That may still be, in words and in theory and to some extent, the law of the case, and has been so asserted in very interesting cases in the United States, although not without some dissent and some qualification. And we are satisfied that in cases of murder, the actual and practical rule whereby the fate of the prisoner is determined should be and is that the burden of proof remains on the government until they have proved their whole case, which includes the killing and the intent, or "the malice aforethought," without which there can be no murder. This evidence may undoubtedly be indirect or circumstantial, and must be so generally, because malice is a condition of mind and purpose. But it would not be enough in modern times to charge A with the murder of B, and rest the charge upon the mere proof that A killed B, unless there were something in the time, place, or circumstance of the killing, or of the conduct of the prisoner in reference to it, which brought home to a jury a belief that he was moved by malice aforethought.—In some of the states, although not generally, the crime of murder has been divided into degrees; and only murder in the first degree is punishable with death.—It should be added, that whenever a person is indicted and

tried for murder, it is competent for the jury to bring in a verdict of manslaughter.

MURDOCK, JAMES, D.D., an American clergyman, born in Westbrook, Conn., Feb. 16, 1776, died in Columbus, Miss., Aug. 10, 1856. He was graduated at Yale college in 1797, and became preceptor successively of the Hopkins grammar school in New Haven, and of the Oneida academy, now Hamilton college, in the state of New York. In Jan. 1801, he was admitted to the Congregational ministry, and in Feb. 1802, was settled over the Congregational parish in Princeton, Mass., where he remained 18 years. In 1815 he was appointed professor of ancient languages in the university of Vermont, and in 1819 accepted the Brown professorship of sacred rhetoric and ecclesiastical history in the theological seminary at Andover, Mass. In 1828 he removed to New Haven, and devoted the rest of his life to study. Ecclesiastical history, the oriental languages, and philosophy were his special objects of pursuit. His principal works are: a translation from the German of Münscher's "Elements of Dogmatic History" (12mo., New Haven, 1830); a translation of Mosheim's "Institutes of Ecclesiastical History," with copious notes (3 vols. 8vo., New York, 1832); an edition of Milman's "History of Christianity," with a preface and notes (8vo., New York, 1841); "Sketches of Modern Philosophy, especially among the Germans" (18mo., Hartford, 1842); a "Literal Translation of the whole New Testament from the Ancient Syriac Version," with a preface and marginal notes (8vo., New York, 1851); and a translation from the Latin of Mosheim's "Commentaries on the Affairs of the Christians before the time of Constantine the Great" (2 vols. 8vo., New York, 1852). He also contributed occasionally to periodicals, and published several sermons, one of which, on the atonement (1828), attracted great attention. He was an honorary member of the New York historical society, vice-president and president of the Connecticut academy of arts and sciences, vice-president of the philological society of Connecticut, and one of the founders of the American oriental society. He received the honorary degree of D.D. from Harvard university in the year 1819.

MURDOCK, JAMES E., an American actor, born in Philadelphia in 1812. He made his début upon the stage in Philadelphia in 1829, and in 1838 first appeared at the Park theatre, New York, as Benedick in "Much Ado about Nothing." In 1840-'41 he was manager of the Chestnut street theatre, Philadelphia. He has since repeatedly appeared in the chief theatres of the United States, and is accounted one of the best genteel comedians on the American stage. He is also distinguished as an elocutionist, and, in conjunction with William Russell, has published a treatise entitled "Orthophony, or Culture of the Voice" (12mo., Boston).

MURE, WILLIAM, a Scottish author, born at Caldwell, Ayrshire, July 9, 1799, died in Lon-

don, April 1, 1860. He was educated at Westminster school and the university of Edinburgh, and completed his studies in Germany, where he imbibed a taste for critical inquiry in various departments of ancient history and literature. In 1829 appeared his first work, "Remarks on the Chronology of the Egyptian Dynasties," followed in 1832 by "A Dissertation on the Calendar of the Zodiac of Ancient Egypt." He subsequently spent much time in travel, and in 1842 published his "Journal of a Tour in Greece." His next and most important production was his "Critical History of the Language and Literature of Ancient Greece," which was left unfinished. Of the 5 volumes which have appeared, the 1st and 2d comprise a careful analysis of the Iliad and Odyssey, which he maintains were composed as an integral work and in their present form; the 3d treats of the lyric poets, and the 4th and 5th of the historians down to the time of Xenophon. He was engaged upon a 6th volume, to embrace the Attic drama, at the time of his death. He also prepared for the press 8 volumes of "Caldwell Papers," relating to the local history of the counties of Renfrew and Ayrshire. He was, after his father's death in 1831, the head of the Mures of Caldwell, a family dating from the 14th century; and he was for many years colonel commandant of the militia of Renfrewshire, which county he represented in parliament from 1846 to 1855, and in 1847-'8 held the office of lord rector of the university of Glasgow.

MUREX, a genus of univalve shells of the class *gastropoda*, found in almost all salt water seas at depths varying from 25 to 60 fathoms. About 180 living species are known, and 160 fossil, chiefly belonging to the eocene formation. Some of the species are remarkable for their very long and slender beak, along which the canal is partly closed. The shells are ornamented with 8 or more longitudinal ridges, from which sometimes proceed rows of long pointed spines. The murexes are particularly interesting from their having been the source of the famous Tyrian dye. It is stated that heaps of broken shells of the *M. trunculus* and caldron-shaped holes in the rocks may still be seen on the Phœnician shore; and on the coast of the Morea there is evidence that the *M. brandaris* was used for the same purpose of collecting from them the purple secretion of which the dye was composed. The ancients bruised the smaller shells in mortars, but took out the animal from the larger ones. Some of the *buccinum* family, as several species of the *purpura*, produce a fluid which gives a dull crimson dye; but these names as used by Pliny were applied to the shells now known as murexes. An imitation of the purple dye prepared from uric acid, treated by nitric acid and combined with ammonia, was discovered by Proust in 1818, and afterward named by Liebig and Vöhler murexide. It is now produced from guano, and is used for the dyeing of foulard silks.

MURFREESBOROUGH, a city and the capital of Rutherford co., Tenn., situated near the centre of the state, on an elevated plain surrounded by the Cumberland mountains, 81 m. by the Nashville and Chattanooga railroad S. E. from Nashville; pop. in 1859 about 3,000. It is well built, chiefly with brick, is lighted with gas, and contains 6 churches (2 Baptist, 1 Christian, 1 Methodist, and 2 Presbyterian), 2 weekly newspaper offices, a foundry and machine shop, and one or two factories. It is the seat of Union university, founded by the Baptist education society in 1848, and having 800 students and a theological department; of Eaton female college, also under the care of the Baptists; of Soule Methodist female college, founded in 1852, and having 150 pupils; of 3 high schools, and of a military institute. The town was established in 1811, and incorporated in 1817, and until 1827 was the capital of the state.

MURIATIC ACID. See HYDROCHLORIC ACID.

MURILLO, **BAROLOMÉ ESTEBAN**, a Spanish painter, born in Seville, where he was baptized Jan. 1, 1618, died there, April 8, 1682. Displaying great aptitude for sketching, he was placed while a boy in the studio of his relative Juan de Castillo. The classical models then accessible to Sevillian painters being few and imperfect, he learned to study nature as it was about him; and his sketches of the ragged, sun-burnt children of Seville and its neighborhood afforded the material for those lively pictures of Spanish low life for which he subsequently became famous. About 1640 his master removed to Cadiz, and Murillo, obliged to depend upon his own resources, remained in his native town painting coarse and hastily executed pictures for the *feria*, or public fair, of Seville. By this sort of work he acquired probably that freedom of touch which characterizes his style; but the few remaining pictures by him of this period possess little merit, either in color or composition. About 1642 Pedro de Moya, a fellow pupil in the school of Castillo, and who had improved his style by studying with Vandyke, returned to Seville. Murillo, seeing the advantages his friend had derived from foreign travel, was filled with the desire to visit some of the older seats of art; and to procure the means he executed a number of pictures for the colonial market, which were speedily distributed by the traders throughout the Spanish American possessions, comprising the greater part, if not the whole, of the paintings by the artist since found in churches and monasteries of the new world, and the number and value of which have been greatly exaggerated. With the money thus acquired he went in 1643 to Madrid, was kindly received by Velasquez, then in the zenith of his fame, and by him introduced to the royal galleries of the capital and the Escorial, where during the next two years he copied the works of Titian, Rubens, Vandyke, Ribera, and Velasquez. Returning to Seville at the end of this time, contrary to the earnest advice of Velas-

quez that he should visit Rome, he entered upon his career as a painter, conscious of his own powers and ready for the execution of great works. His first important commission was from the friars of the convent of San Francisco, for the cloisters of which he painted 11 large pictures in the *frío*, or first of the 8 styles which are usually distinguished in his works. According to Ford, it was based on the works of Ribera and Caravaggio, and was dark, with a decided outline. His second manner was the *calido*, or warm, wherein his coloring was improved, while his drawing was still well defined and marked. His third style was the *vaporoso*, or misty, vaporous, and blending. (See Ford, "Handbook of Spain," p. 191.) The cloisters were burned in 1810, and the greater part of the pictures carried off by Marshal Soult, called by Mr. Stirling the "plunder-marshal-general," whose wholesale appropriation of the art treasures of Spain during his stay in the country, if indefensible on principle, was probably the means of preserving many choice pictures from neglect and the ravages of time. "In these works," says Sir Edmund Head, "Murillo seems to have burst upon Seville as a great painter whose existence was hardly suspected before." Commissions flowed in upon him, and in 1648 he was married to Doña Beatriz de Cabrera y Sotomayor, an Andalusian lady of wealth and rank. Soon after he adopted his *calido* or second style, some of the earliest and most felicitous examples of which were "Our Lady of the Conception," the "San Leandro" and "San Isidro," the "Nativity of the Virgin," and the "San Antonio de Padua." The last, esteemed one of his finest performances, now hangs in the cathedral of Seville, for which it was originally painted, but in 1838 was, according to Ford, "cruelly retouched." In 1658 Murillo, in conjunction with Valdes Leal and the younger Herrera, undertook the establishment of a public school of art in Seville, which was first opened in 1660, and of which he assumed the direction during that year. To this period may be ascribed his 4 large semi-circular pictures, executed for the church of Santa Maria la Blanca in Seville, and carried by Soult to Paris. Two of these, representing the legend of the dream of the Roman patrician which led to the building of Sta. Maria Maggiore in Rome under Pope Liberius, were subsequently restored to Spain, and now hang in the academy of San Fernando in Madrid. They indicate the commencement of the *vaporoso* style, and are magnificent specimens of the artist's powers. Between 1660 and 1674 was executed for the *caridad*, an almshouse outside the walls of Seville, a celebrated series of pictures, the commission for which was given to Murillo by his personal friend and patron, Miguel de Mañava Vicentelo de Lara, by whom the edifice was rebuilt. Five of these, "Abraham receiving the three Angels," the "Return of the Prodigal Son," the "Healing of the Cripple," "St. Peter released from Prison by the Angel," and

"Santa Isabel (St. Elizabeth) of Hungary," were carried off by Soult. The first two were sold to the duke of Sutherland; the 3d was bought by Mr. Tomline, an English collector, for 160,000 francs; the 4th is in Russia; and the 5th, which the marshal, it is said, offered as a bribe to Napoleon to overlook his own stealings, is now, with the two pictures from Sta. Maria la Blanca, in the academy of Seville. It is called *El tiñoso*, from the boy with the scald-head to whom the saint is ministering, and, apart from the almost divine beauty of Sta. Isabel, affords admirable specimens of Murillo's facility in painting the beggar boys and vagabonds of Seville. Of these accessories to his pictures Ford says: "The beggars are beyond price; none could represent them and Franciscans like Murillo, and simply because he painted them the most, and drew only what he saw." Of the original series still remaining in the *caridad*, the chief are "Moses striking the Rock," "The Charity of San Juan de Dios," and "The Miracle of the Loaves and Fishes," works conceived with all the artist's strength in the maturity of his powers. Subsequent to 1675 he painted a series of about 20 pictures for the convent of the Capuchins in Seville, of which, thanks to the foresight of the monks in sending their collection temporarily to Cadiz during the occupation of Seville by the French, 17 are now preserved in the museum of the latter city. One of the best of these, "The Charity of St. Thomas of Villanueva," presents many striking studies of street nature, and was called by the artist *su lienso*, "his own picture." Another celebrated picture formerly in the chapel of the monastery, representing the Virgin and child, is said to have been painted on a *servilleta*, whence it was called the "Virgin of the Napkin." He subsequently executed fine series of pictures for the *hospital de los venerables* and the Augustinian convent of Seville, and at this, as at other periods of his life, a multitude of miscellaneous works, generally of a religious character. Preëminent among them were those devoted to the illustration of the immaculate conception of the Virgin, a dogma promulgated in Spain about the time of Murillo's birth, and which has been called the "crowning and protecting mystery" of the Spanish people. In depicting the "woman clothed with the sun, and the moon under her feet, and upon her head a crown of stars," Murillo was unapproachable; and from the frequency and fondness with which he represented the subject, he was called *el pintor de las concepciones*, "the painter of the conceptions." A memorable example of this style of picture is the "Immaculate Conception," purchased at the sale of Marshal Soult's collection in 1852 by the French government for 635,000 francs, and now deposited in the Louvre, in which the Virgin appears in a state of ecstatic beatitude, borne aloft in a golden ether to heaven by a multitude of cherubs, who are painted with inimitable sweetness. Several similar works, but with fewer

accessories, attributed to Murillo, are owned in the United States. His remaining works are distributed among the royal and private galleries of Europe. The Louvre contains a considerable number, the Pinakothek in Munich 2 or 3 admirable specimens of his beggar boys, and Dulwich gallery a very rich collection, including the celebrated "Flower Girl." Such, however, has been the mania of late years for his works, that his name has been applied indiscriminately to productions utterly unworthy of his pencil, and many of the pictures of peasants and beggars attributed to him are supposed to be by his followers or pupils. A short time before his death Murillo went to Cadiz to paint the "Espousals of St. Catharine" over the high altar in the Capuchin church of that city, and while engaged upon the work stumbled and fell from the scaffolding, receiving an injury which proved fatal. He was buried in the church of Santa Cruz in Seville, before a picture of the "Descent from the Cross" by Pedro Campana, which he had greatly admired in his life. The French in 1810 levelled the church to the ground, and "cast out the ashes of Murillo to the winds."—Murillo was essentially a painter of religious subjects, but of that class of religious subjects in which female or infantile purity and beauty form the controlling element. Without trick or deception, he seems to have possessed the power of adapting the higher subjects of art to the commonest understandings, and succeeded in at once captivating the learned and unlearned. Hence the universal popularity of his works throughout Europe, notwithstanding Ruskin places him among the "base" artists. As a colorist he was preëminent. Compared with his great countryman and contemporary, Velasquez, he was more artless and tender, but less masculine and intellectual. As a landscape painter he occupies a respectable position, although his scenery is too often conventional and merely accessory. He painted a few good portraits.—See "Ford's Handbook of Spain" (8d ed., 1856); Stirling's "Annals of the Artists of Spain;" Head's "Handbook of the Spanish School;" and Cunningham's "Life of Wilkie."

MURNER, THOMAS, a German satirist and opponent of the reformation, born in Strasbourg, Dec. 24, 1475, died about 1536. He studied at the principal universities of Europe, devoting himself particularly to theology and philosophy, and early gained a reputation for ability, marred however by a want of earnestness and a quarrelsome disposition. He lost a place in the conventual Latin school of Strasbourg by his invective against Wimpfeling, and led afterward an unsteady life, preaching for some time at Frankfort-on-the-Main and other places, but incurring generally the displeasure of his congregation by the coarse personalities of his sermons. He was successively expelled from Freiburg, Treves, and Venice. He seems to have resumed his functions in the conventual school of Stras-

bourg in 1519, and became one of the most virulent opponents of the reformation. In 1528 he repaired to England in compliance with an invitation from Henry VIII, but troubles in his convent compelled him to return. Some of his writings against the reformation had already been burned by order of the diet of Worms; and in order to elude the vigilance of the authorities he established a press of his own, which however was destroyed by a mob, together with his house, and he was compelled to flee to Switzerland, whence he was in time likewise expelled. The latter part of his history is not known, although he is supposed to have lived in misery and to have died in Heidelberg. In 1506 he had been crowned as poet laureate by the emperor Maximilian; and his *Narrenschwörung* (Strasbourg, 1512), of which his *Der Schelmen Zunft* (Frankfort, 1512) may be regarded as a continuation, is one of the most remarkable imitations of Sebastian Brant's celebrated satirical poem entitled *Narrenschiff*. He wrote *Charitadum logice*, &c. (Cracow, 1507), and other Latin works; prepared a German version of Virgil and other translations; and was also regarded as the editor of *Bulenspiegel*. But he is chiefly remembered by his writings against Luther and the reformation. His most celebrated satirical work is entitled *Von dem grossen Lutherischen Narren* (Strasbourg, 1522; new ed., Zürich, 1848).

MURPHY, ARTHUR, a British dramatist and miscellaneous author, born in Oloonquin, near Elphin, in the county of Roscommon, Ireland, Dec. 27, 1727, died in Sept. 1805. He was educated at the Roman Catholic college of St. Omer, spent some years in a banking house in London, and in 1756 was admitted to Lincoln's Inn. His first literary undertaking was the publication of a weekly paper entitled the "Gray's Inn Journal," which he conducted for two years. In 1758 appeared his first dramatic performance, "The Upholsterer," a farce, directed against politicians, which proved very successful, followed by "The Orphan of China," "The Way to Keep Him," "All in the Wrong," "The Citizen," "The Old Maid," &c. In 1762 he was called to the bar, but at the end of 15 years quitted his profession in disgust, and devoted the remainder of his life to literary pursuits. In 1786 appeared an edition of his works in 7 vols. 8vo., containing, in addition to the dramatic pieces above mentioned, his "Three Weeks after Marriage," "Zenobia," "The Grecian Daughter," &c. In 1792 he published an indifferent essay on the life and genius of Dr. Johnson, followed in 1798 by a translation of Tacitus in 4 vols. 4to., dedicated to Edmund Burke, and by a life of Garrick. At various times in his life he engaged in political controversies, and edited journals opposing Mr. Fox, the first Lord Holland, and Wilkes's "North Briton." His plays are his best performances, and some of them, including "The Way to Keep Him" and "Three Weeks after Marriage," still retain possession of the stage.

MURRAIN (Gr. *μαραινω*, to waste, weaken; Lat. *morior*, to die), a malignant epidemic among cattle. It has been known from the most remote periods, and has been described by ancient authors. It has prevailed at different periods in almost all countries, often producing the most terrible devastations. Like all epidemic diseases, its character and types have materially varied at different periods, the epidemics of recent times being much less virulent than those which prevailed during the last century. The earliest record which we have of murrain is contained in the account of the destruction of the Egyptian cattle (Exod. ix. 2-6): "If thou refuse to let them go, and wilt hold them still, behold the hand of the Lord is upon thy cattle which is in the field; . . . there shall be a very grievous murrain. . . . To-morrow the Lord shall do this thing in the land. And the Lord did that thing on the morrow, and all the cattle of Egypt died." Visitations of plague or murrain are mentioned by Homer, Hippocrates, Plutarch, Livy, and Virgil. The last of these writers gives a detailed description of the murrain as it desolated the Roman farms. Its character as described by Virgil does not differ materially from the accounts of the disease which has visited various portions of continental Europe in modern times. It was a highly inflammatory fever, and was accompanied with tumors, carbuncles, ulcers, and purulent deposits throughout the whole body. In the year 876 a murrain broke out among the cattle over the whole of Europe; this terrible epidemic has been described by Cardinal Baronius. In the 9th century a murrain destroyed all the cattle in the greater portion of Charlemagne's dominions. At two different periods of the 16th century murrain ravaged the Venetian states. In the 17th century great numbers of cattle were destroyed by this disease in most of the provinces of France; and again in the 18th century, various and repeated visitations of murrain spread havoc and terror throughout Great Britain, and in many countries of continental Europe. These continued visitations eventually led to the foundation of veterinary colleges, and to proper instruction in the veterinary art. In 1745, the disease having appeared in France and Germany, it passed into Holland, where it destroyed more than 200,000 cattle. From Holland the disease crossed over to Great Britain, where it created incredible devastations during a period of 12 years. In the 3d year of this period, according to the calculations of the public commissioners, 240,000 cattle were directly or indirectly destroyed by the pestilence. Since the latter part of the 18th century the visitations of this epidemic have been comparatively few, and the disease appears to have lost much of its virulence. The alterations in its character, and the decrease in its devastations, are undoubtedly due in a great measure to the preventive as well as curative treatment which has of late years been pur-

sued.—The accounts afforded us by the historians of these early malignant epidemics, although mostly written by medical men, are very vague and unsatisfactory. Particularly is this the case with regard to the symptoms of the disease which they describe. Two Italian physicians, Rammazini and Lancisi, have handed down very intelligent and consistent accounts of the epidemics as they prevailed in their own country in the early part of the 18th century. The epidemics of the middle of this century produced many written descriptions of the affection, among which stands preëminent that of Sauvages, the celebrated professor of medicine at Montpellier. The British visitation of the malady in 1757 elicited an excellent work from the pen of Dr. Layard, a physician of London, which was translated into several languages. According to the accounts of the Italian physicians, the disease was ushered in with shivering, followed by extreme heat, great thirst, difficulty of breathing, total loss of appetite and rumination, together with extreme debility; a thick, fetid, mucous discharge from the mouth and nostrils soon succeeded, as also frequent bloody and fetid digestions from the bowels. About the 5th day a pustular eruption appeared in the mouth, which covered the tongue and the pharynx. Abscesses, loss of the hair, and a carious condition of the bones soon followed. The animal died generally between the 5th and the 9th day. On examination after death, hydatids were found in the brains and lungs, which contained a most infectious gas. Ulcers were found at the root of the tongue, and the intestines were in a gangrenous condition. The third stomach always contained a hard, black, infectious mass, which adhered closely to the living membrane, and could scarcely be separated from it. Lancisi remarks that he found no medical treatment of any avail, although the use of setons and the actual cautery were sometimes beneficial. In this statement Rammazini fully concurs, and says that the only cattle that did escape destruction were those in which either setons, cautery, or natural tumors and ulcerations had produced a copious discharge of thick, purulent, and fetid matter. Dr. Layard describes murrain as commencing with a difficulty of swallowing, itching of the ears, shaking of the head, with excessive weakness and staggering gait, which occasioned a continued desire to lie down; a sanious fetid discharge invariably appeared from the nostrils and eyes; the cough was frequent and urgent, and the febrile symptoms well marked. After two days there was a constant scouring of green fetid dung, which tainted every thing around; even the breath, perspiration, and urine became highly fetid. Little tumors or boils were very commonly felt under the skin; and if about the 7th or 9th day these eruptions became larger and boils or buboes appeared with a lessened discharge of feces, they proved critical, and the animal

often recovered; but if on the contrary the alvine discharges continued, and the breath became cold, and the mouth dark in color, he informs us that death invariably followed. Sauvages describes the murrain as showing itself by cold shivering, nose excoriated with an acrid discharge from it, and by purging after the first two days, previous to which however there was often costiveness. Great tenderness about the spine and withers was also a characteristic together with emphysema or a blowing up of the skin by air discharged underneath it. Dissections of those that died of this disease, according to Sauvages, showed marks of great inflammation and of a great putrid tendency, but the solid parts seldom ran into gangrene. The paunch was usually filled with undigested matter, and the gall bladder was also commonly distended with acrid, thick, brownish bile. Goelich, who also dissected these subjects, describes the gall as particularly profuse and intolerably fetid. He represents the entire alimentary canal as excoriated. So also Lancisi, contrary to Sauvages, found the viscera of the chest and belly in some cases sphacelated and gangrenous. Gazole describes the murrain as accompanied by pustulous sores; and so great was the putrid tendency, that even the milk before it dried up, which it usually did before the 4th day, became fetid.—As to the treatment of this disease, all authors recommend bleeding in the early stages; afterward sedatives and tonics according to circumstances; the animals infected to be at once separated from the healthy, and to be placed in open airy sheds. Dr. Lancisi advised the body to be washed in aromatic herbs, and various applications to be made to the sloughing pustules. When recovery takes place, it is usually a very slow process. All these writers speak of the importance of the preventive treatment. This consists in a careful supervision of the cattle several times during the day, the immediate removal of the animal at the very onset of the disease, the fumigation and cleansing of the buildings, and the immediate burial of all dead bodies with the hides unremoved.—Such is a concise account of the history and symptoms of this malignant epidemic, as it has been transmitted to us by various writers. During the present century the epidemics which have occasionally appeared in the various countries of Europe, have been comparatively mild, and have yielded much more readily to treatment. The murrain of the present day is usually classed by writers under diseases of the respiratory system, inasmuch as this portion of the frame is first attacked. But it very soon assumes such a low typhoid character, its virulence expending itself upon every portion of the body, particularly upon the abdominal viscera, that it would be more exact to consider it as essentially an abdominal affection. It appears much more frequently in woody, marshy districts, among undrained lands, and affects chiefly cattle that have been

exposed and half starved. It is to be distinguished by some or the greater portion of the following symptoms: a frequent and painful cough, remaining in some cases for several days without any other marked symptom; heaving of the flanks; a small, hard, frequent, and often irregular pulse; the mouth hot; the evacuations from the bowels at first hard and black, and then very liquid, black, and exceedingly offensive; extreme tenderness along the spine, and particularly over the loins. There is a bloody brownish discharge from the nostrils and mouth, great swelling of the eyes, constant grinding of the teeth, spasmodic contractions about the nostrils, and convulsive movements of the head. As the disease progresses, the eyes become dull, the pulse more feeble, the respiration more hurried, and the feces are bloody and horribly fetid. Even the breath and perspiration become offensive, and the animal staggers as he attempts to walk. During the latter stages small tumors or boils appear on various portions of the body, which go on to supuration, during the process of which the animal most frequently dies. The treatment of this, as of all virulent epidemics, has proved most unsatisfactory. Bleeding in the early stages may sometimes prove beneficial, if the febrile symptoms are well marked. Tonics, however, are called for early in the disease, and should be administered freely. The peculiar fetid diarrhoea must be met with astringents. The chloride of lime has been found to be the best external application for the pustular and sloughing boils. Hurtrel d'Arboval, an eminent French practitioner, advises the opening of the tumors and the canterization of them with lunar caustic, and the administration internally of bark and sulphuric acid. Inoculation for this disease has been practised, but with very uncertain results. The preventive treatment must consist in first separating the infected from the healthy, and precluding their future intercourse. The unhealthy districts must be put under strict quarantine. The houses in which the affected may have been, and all the appointments about them, must be disinfected. The bodies of the animals who die from the disease should be buried deeply, and their skins should be buried with them.—As to the contagiousness of this disease, there have been, as there always will be with regard to all epidemics, a variety of opinions. If we can judge from the propagation of murrain in certain localities in Europe, we should consider that it was eminently contagious. In our own country we have thus far been happily ignorant of this terrible plague. We consider the disease in question as essentially different in its nature from the affection which has recently been introduced from Holland into Massachusetts under the name of pleuro-pneumonia. (See *PLEURO-PNEUMONIA*.)—The term murrain has also been applied to a virulent disease of the skin which attacks hogs, and which is somewhat allied to leprosy.

MURRAY, a N. W. co. of Ga., bordering on Tenn., bounded W. by the Connasauga river and drained by its branches; area, 820 sq. m.; pop. in 1859, 6,671, of whom 1,420 were slaves. The surface is elevated, and the soil generally fertile. Gold, silver, lead, and zinc are found. The county has been divided since the U. S. census of 1850. Capital, Spring Place.

MURRAY, a river of Australia, which rises in the Warragong mountains, in lat. $36^{\circ} 20' S.$, long. $148^{\circ} 15' E.$ Its course is very tortuous, the curvatures being short, abrupt, and almost incessant. After descending from the highlands, it flows nearly westward to long. $144^{\circ} 25' E.$, then takes a N. W. direction to Mt. Lookout, where again turning it proceeds to Elbow, in lat. $34^{\circ} S.$, long. $139^{\circ} 46' E.$, and there bending suddenly runs S. S. W. to Lake Victoria, into which it falls at Wellington in lat. $35^{\circ} 30' S.$ This river and its tributaries drain an area of about 500,000 sq. m. Its length is about 900 m., and its average breadth from 100 to 150 yards. It overflows its banks periodically, and sometimes rises 30 or 40 feet above its ordinary level. During this season it is navigable to within 90 miles of its source, and then steamers and barges ply regularly between Wellington, Albury, and the intermediate towns. Its principal affluents are the Goulburn, Campaspe, Murrumbidgee (with the Lachlan), and Darling. Lake Victoria, which connects it with the sea, is about 50 m. long and 40 m. broad, but in general very shallow. The entrance to it from the sea not being navigable, a tramway has been constructed between Goolwa and Port Elliot, which is worked in connection with the river steamers.

MURRAY, ALEXANDER, a commodore in the U. S. navy, born at Chestertown, Md., in 1755, died while in command of the navy yard at Philadelphia, Oct. 6, 1821. In 1776 he was appointed a lieutenant in the continental navy, which then had but a nominal existence; and there being no employment for him afloat, he volunteered for the army, and served with credit through the campaigns of 1776-'7 as lieutenant and captain in the 1st Maryland regiment, participating in the battles of White Plains and Flatbush. About the time of the evacuation of New York by the British forces, he was seriously injured by the bursting of a piece of ordnance in a battery at which he was stationed. At the close of the campaign of 1777 he retired from the army, and was appointed by the marine committee to the command of a letter of marque, in which he was captured by a British squadron and carried into New York. He was soon exchanged, and served as 1st lieutenant in the Trumbull, 28, Capt. James Nicholson, distinguishing himself highly in the gallant defence made by that ship against the Iris and Gen. Monk off the Delaware. In 1798 he was promoted to the rank of captain, and served during the "French disturbance" very actively and usefully in the West Indies, at first in command of the *Montezuma*, 20, and

afterward of the Constellation frigate. In 1802, at the commencement of the war with Tripoli, he again commanded the Constellation in the Mediterranean; and an attack which he made with this ship upon a flotilla of 17 Tripolitan gun boats was the first affair of this war. The gun boats took refuge in shore among the rocks, and it not being prudent to send the boats of a single frigate to attempt their capture, Capt. Murray hauled off. The subsequent services of Commodore Murray were principally upon shore stations, and mostly at Philadelphia. At the time of his death he was senior officer of the navy.

MURRAY, ALEXANDER, D.D., a Scottish clergyman, born in Dunkitterick, Kirkcudbrightshire, Oct. 22, 1775, died in Edinburgh, April 15, 1813. He was the son of a shepherd, was placed at school by his uncle in 1784, and after some time was able to devote part of each year to teaching, giving the rest to study. He made himself acquainted with French, Latin, Greek, Hebrew, Anglo-Saxon, Welsh, and Arabic. In 1794 the Rev. Dr. Baird of Edinburgh procured him admission to the university, where after two years a bursary was conferred on him. He now began to study for the church, and in 1806 was ordained and appointed assistant to Dr. Muirhead, minister of Urr in Kirkcudbrightshire, whom he succeeded as pastor in 1808. In 1811 he translated a letter in Ge'ez or old Ethiopic, addressed to the king by the sovereign of Tigre in Abyssinia; and in the following year he was elected to the chair of oriental languages in the university of Edinburgh. His most important works are: "Outlines of Oriental Philology" (Edinburgh, 1812), and "History of the European Languages, or Researches into the Affinities of the Teutonic, Greek, Celtic, Sclavonic, and Indian Nations" (1813). He also edited Bruce's "Travels" for Constable, the Edinburgh publisher, and contributed some philological papers to the "Edinburgh Review."

MURRAY, JAMES STUART, earl of, regent of Scotland, born about 1538, killed at Linlithgow, Jan. 23, 1570. He was an illegitimate son of James V. and Lady Margaret, daughter of John, 4th Lord Erskine, and in the 3d year of his age was appointed by his father prior of St. Andrew's. He afterward acquired the priory of Pittenweem, and that of Mâcon in France, *in commendam*, with a dispensation to hold three benefices. In 1548, on the invasion of Scotland by Lords Grey de Wilton and Clinton, the one by land, the other by sea, the young prior of St. Andrew's repelled a descent made by the latter upon the coasts of Fife, and drove back the invaders to their ships with great slaughter. In the same year he accompanied his sister, Queen Mary, to the court of France. In 1557 he was one of the commissioners sent from Scotland to witness the ceremony of marriage between Mary and the dauphin of France, afterward Francis II., and soon after solicited from the former the earldom of Murray, but was refused.

In the contest between the queen regent and the lords of the congregation, he sided alternately with both parties, but finally joined the latter; and when in 1559 the congregation resolved to take the government into their own hands, he was one of the council appointed for civil affairs. Soon after the death of the queen regent in June, 1560, he became one of the lords of the articles, and on the death of Francis II. was commissioned to proceed to France and invite Mary to Scotland. On her return he became her confidant, adviser, and prime minister, protected her in the exercise of her religion, obtained from her a proclamation favorable to the reformers, cleared the border of the freebooters, and ruled the country with judgment and ability. He was rewarded with the title of earl of Mar, and married soon after Agnes Keith, daughter of the earl marischal. The entertainments given by Mary in honor of the occasion were so splendid, that Knox read Lord James a lecture, in which he said: "Unto this day the kirk of God hath received comfort by you and by your labors, in the which if hereafter ye be found fainter than before, it will be said your wife hath changed your nature." Lord Erskine claiming the earldom of Mar as his peculiar right, Lord James resigned it and received instead the earldom of Murray, and shortly after defeated at Corrichie the earl of Huntley, an unsuccessful competitor for power and popularity. Although governing Scotland judiciously and with undisputed authority, he was too lukewarm a Protestant for the extreme reformers, who lamented the protection he afforded to the queen in the use of the mass, and particularly his defence of her and her ladies in what Knox called "the superfluities of their clothes." Between Knox and Murray a coolness sprung up in consequence, which continued a year and a half; but they were brought together again by their mutual opposition to the marriage of Darnley and Queen Mary. Murray had endeavored to prevent that marriage, and finally resorted to arms; but being pursued by his sister at the head of a superior force, he was compelled to fly to England. On the murder of Rizzio, however, he was recalled, and apparently reconciled to the queen. It is not certain whether or not he was accessory to the murder of Darnley. He left Edinburgh the day before, and was also absent from Scotland during the trial of Bothwell and his subsequent marriage with Mary. After the dethronement of the queen and her confinement in Lochleven castle, Murray was appointed regent of Scotland, Aug. 22, 1567. In this situation he acted with vigor and discretion, and kept the country in a state of tranquillity. On the escape of the queen, he refused to resign his power, defeated her and her adherents at Langside, March 18, 1568, and followed up the victory by destroying the strongholds of her friends, and more firmly establishing the government. When Mary was tried at York for complicity in the murder of

Darnley, Murray bore the most unqualified testimony against his unhappy sister. In passing through the streets of Linlithgow, he was shot through the body by a bullet fired from a window by James Hamilton of Bothwellhaugh, and died the same night. Bothwellhaugh's conduct has generally been ascribed to revenge for a personal injury, but there is reason for believing that he acted as the executioner of a doom pronounced on Murray by his enemies in secret conclave. The following passage in a letter from Queen Mary to Archbishop Beaton, published by Prince Labanoff de Rostoff in his *Lettres, instructions et mémoires de Marie Stuart* (London, 1845), has been cited in illustration of this affair: "That which Bothwellhaugh hath done hath been without my command, but I feel under obligation to him, and all the more so that I was not in the plot. I wait for the accounts which ought to be rendered of my dowry that I may arrange my establishment, in the which I shall not forget the pension to this Bothwellhaugh." Whatever may be thought of the means which Murray used to secure the supreme power, he was unquestionably in the exercise of it one of the best and ablest rulers that Scotland ever possessed, and is known in Scottish history as "the good regent."

MURRAY, JOHN, an American clergyman, born in Alton, Hampshire, England, Dec. 10, 1741, died in Boston, Mass., Sept. 3, 1815. He was the son of pious parents, who brought him up with great strictness, and with whom in his 11th year he removed to Cork, Ireland. Under the influence of Wesley and Whitefield he became at a comparatively early age a convert to Methodism, and an occasional preacher in Wesley's connection. About 1760 he returned to England, and a few years later adopted the doctrines of Universalism promulgated by James Kelly, for which he was excommunicated at Whitefield's tabernacle in London. In 1770 he emigrated to the United States, and entered at once upon the career of a public preacher. New York and New Jersey were the first scenes of his labors, and subsequently he preached in Newport, R. I., Boston, Portsmouth, N. H., and other places in New England, in some of which his peculiar doctrines subjected him to opposition, and occasionally to open violence. At Gloucester, Mass., where he took up his residence in the latter part of 1774, upon the representations of certain people that he was an emissary of the British government in disguise, a vote was passed ordering him forthwith to depart; but through the exertions of his friends he was enabled to remain and preach. In the spring of 1775 he was appointed chaplain of the 3 regiments of the Rhode Island line encamped before Boston, with several of whose officers, including Greene and Varnum, he had been on terms of intimacy. The rest of the chaplains united in petitioning Washington to remove Murray from his office, but without effect, his appointment being confirmed in general orders. His con-

nection with the army was soon after terminated by a severe illness, and he returned to Gloucester, where he was established over a society of Universalists. In 1788 he became plaintiff in an action brought to recover property belonging to persons of his denomination, which had been appropriated to the expenses of the original parish of Gloucester, on the ground that the Universalists were not a society legally authorized and vested with civil and corporate powers. The decision of the court in his favor established an important principle in the constitution of religious societies. He participated in the proceedings of the first Universalist convention, which met at Oxford, Mass., in 1785, and adopted the name of Independent Christian Universalists as their denominational title; and subsequently for a number of years he was a delegate to the general convention of the Universalists. In 1788 he made a brief visit to England, and in 1798 was installed over a society in Boston, where he passed the remainder of his life. In 1809 he suffered an attack of paralysis which incapacitated him from further active labor in the ministry. From his activity in disseminating his denominational opinions, Murray is considered the father of Universalism in America. His doctrines, however, differed essentially from those now recognized by Universalists. "He believed that the Creator, enrobed in humanity, descended to the earth, and thus became the Saviour of sinners; that he was exhibited as a holy spirit of consolation, who took of the things of Jesus, and showed them to the world; that as man, composed of body, soul, and spirit, is but one man, so the Father, Son, and Holy Spirit are one God." (Whittemore's "Modern History of Universalism.") As a preacher he was distinguished by eloquence and earnestness. He published 8 volumes of letters and sketches of sermons, and wrote an autobiography, of which the 8th edition, with additions, was published in 1860 (12mo., Boston).

MURRAY, JOHN, a Scottish physician, chemist, and geologist, born in Edinburgh in 1778, died there, June 22, 1820. He had been a pupil of Dr. Joseph Black, but commenced his career as an apothecary in his native city. He afterward delivered a course of lectures on chemistry, and another on materia medica and pharmacy. In geology he was a zealous Neptunian, and in reply to Playfair's "Illustrations of the Huttonian Theory of the Earth" (1802), published his "Comparative View of the Huttonian and Neptunian Theories." The most important of his other works are: "System of Chemistry," "Elements of Chemistry," and "System of Materia Medica and Pharmacy."

MURRAY, JOHN, an English publisher, born in London, Nov. 27, 1778, died June 27, 1848. He was of Scottish descent, and his father, whose name was MacMurray, established himself in 1768 as a bookseller in Fleet street, London. After a good education acquired at a number of schools, at one of which he lost

the sight of an eye by an accident, he was left in his 15th year by his father's death to conduct the business, in which he was assisted by Mr. Highley the shopman, whom he subsequently took into partnership. In 1808 he terminated this connection, and, entering a wider sphere of business, was thenceforth known as one of the most enterprising and liberal publishers of London. By coming forward to the assistance of a number of young men who had become involved in some pecuniary loss in conducting a periodical called the "Miniature," he secured several influential friends, through whom he became known to Mr. Canning. With the latter he matured in 1807 a project for the establishment of the "Quarterly Review" as a means of counteracting the influence of the whig "Edinburgh Review;" and securing the coöperation of George Ellis, the Hebers, Barrow, Gifford, and others, he commenced in 1809 the publication of the new periodical, which under the editorial supervision of Gifford soon attained a circulation of 12,000 copies. The "Quarterly," after a successful career of more than half a century, is still the property of the publishing house of John Murray. In 1810 Mr. Murray made the acquaintance of Lord Byron, to whom he paid £600 for the first two cantos of "Childe Harold," and whose entire works he subsequently published. Of his generosity and consideration toward the poet, both during and after the life of the latter, many anecdotes are related; and Byron's correspondence with him, published in Moore's "Life of Byron," affords an evidence of the friendly relations existing between them. In 1812 he removed to Albemarle street, where the business is still carried on by his son and successor, John Murray, and where a long line of literary celebrities, including Scott, Byron, Campbell, W. Spencer, Bishop Heber, the elder Disraeli, Hallam, Mme. de Staël, Crabbe, Southey, Washington Irving, and Lockhart, were wont to assemble at the hospitable table of the publisher, rendering the locality a classic spot. Of the numerous important works issuing from the press of Murray, it may suffice to mention the voyages and travels of Mungo Park, Belzoni, Parry, Franklin, Denham, Clapperton, and Layard; the series of the "Family Library;" the histories of Hallam, Lord Mahon, Grote, Ranke, Sir Gardiner Wilkinson, and Mrs. Markham; the "Sketch Book," "Tales of a Traveller," "Life of Columbus," and other works by Washington Irving; the "Domestic Cookery," of which 800,000 copies were published; the despatches of the duke of Wellington; the dictionaries of William Smith; an elaborate series of handbooks of travel; and the works of Crabbe, Heber, Lockhart, Milman, Head, Gleig, Kugler, Lord Campbell, Leake, Borrow, Davy, Rawlinson, Mrs. Somerville, Lyell, Murchison, &c. In 1826 he was persuaded into establishing a daily journal called the "Representative," which proved a failure; but in general his good judgment and tact as a busi-

ness man rendered his enterprises successful, and the publications emanating from his house were for the most part books of merit, his imprint being one of their best recommendations. His liberality to authors was a distinguishing trait in his character, and he sometimes made heavy pecuniary sacrifices to gratify others, as in the case of the autobiography of Lord Byron, which he surrendered to Moore on the representation that the publication of it might injure the reputation of the living as well as the dead.

MURRAY, LINDLEY, an English grammarian, born in Swatara, Lancaster co., Penn., in 1745, died near York, England, Feb. 16, 1826. He received his primary education in Philadelphia, in the academy of the society of Friends; and after the removal of his father to New York in 1758, he was placed for a time in school, and then entered a counting house, being destined for the mercantile profession. Having received a severe chastisement, he privately left his father's house, went to Burlington, N. J., and in a seminary in that place acquired a strong love of study. On returning to New York he continued his classical studies, and also entered a law office, in which John Jay was a fellow student. About the age of 21 he was admitted to the bar, and his practice soon became extensive. When the revolutionary war broke out, he retired to the country on account of his health, and there remained 4 years. But the want of pecuniary means compelling him to return, he engaged in mercantile pursuits, and by the close of the war his fortune had become so ample that he was enabled to retire from business. Impaired health soon induced him to go to England with his family. He had purposed to remain only two years; but his physical infirmities and the local attachments he formed led him to become a permanent resident. He purchased an estate at Holdgate, about a mile from York, and occupied himself chiefly with literary pursuits. In 1787 his first work, "The Power of Religion on the Mind," was published anonymously, and has passed through 17 editions. His "Grammar of the English Language," first issued in 1795, and enlarged and improved in successive editions, for many years superseded all others, and has become the basis of most of those since published. Two years after, he published "English Exercises," and a "Key" designed to accompany the grammar; and subsequently an "English Reader," an "Introduction to the English reader," and an "English Spelling Book." He also published French reading books of a character similar to his English ones. His last publication was a selection from Horne's "Commentary on the Psalms," and the "Duty and Benefits of Reading the Scriptures." His works have been very popular both in England and America, and were very lucrative. His autobiography, finished in 1809, was published posthumously.

MURRAY, NICHOLAS, D.D., an American clergyman, born in Ireland, of Roman Catholic parents, in Dec. 1808. In 1818 he came to Amer-

ica, and became an apprentice in the printing establishment of Harper and brothers. Shortly after, having become a Protestant, he entered upon a course of study for the ministry, was graduated at Williams college in 1826, studied theology at Princeton, and in 1829 became pastor of the Presbyterian church in Wilkesbarre, Penn. In 1834 he was settled over the first Presbyterian church at Elizabethtown, N. J., where he has since remained. In 1849 he was elected moderator of the Presbyterian general assembly. Dr. Murray is best known by his "Letters to the Right Rev. John Hughes, Roman Catholic Bishop of New York" (New York, 1848; new ed. enlarged, 1855), under the signature of Kirwan. He has also published "Notes, Historical and Biographical, concerning Elizabethtown, N. J." (Elizabethtown, 1844); "Romanism at Home" (1852); "Men and Things as I saw them in Europe" (1853); "Parish and other Pencilings" (1854); and "The Happy Home" (1859).

MURRAY, PATRICK, 5th Baron Elibank, a Scottish soldier and author, born in Feb. 1708, died Aug. 8, 1778. In 1738 he was admitted to the Scottish bar; but not liking the legal profession, he entered the army the same year, and in 1740 was lieutenant-colonel in the expedition to Carthage. Afterward he turned his attention to literature, and published "Thoughts on Money, Circulation, and Paper Currency" (Edinburgh, 1758); an "Inquiry into the Origin and Consequence of the Public Debts"; "Queries relating to the Proposed Plan for altering Entails in Scotland" (1765); "Letter to Lord Hailes on his Remarks on the History of Scotland" (1778); and "Considerations on the Present State of the Peerage of Scotland" (1774). In politics he was an adherent of the exiled house of Stuart, with whom he maintained a secret correspondence.

MURRAY, SIR ROBERT, first president of the royal society of London, born in Scotland about the beginning of the 17th century, died in June, 1673. In his youth he entered the French service, and rose to the rank of colonel. Subsequently returning to Scotland, he became an ardent supporter of Charles I., and afterward of Charles II., the latter of whom in 1651, during his brief reign in Scotland, appointed him justice clerk and lord of session. During the protectorate his offices were taken from him, but he received them again at the restoration. He now appeared as a prominent member of a small club which had been lately established in London by Boyle, Lord Brouncker, and others, for the discussion of questions in natural science, or, as it was then termed, "the new philosophy," and which by Sir Robert Murray's efforts obtained a royal charter as a regular scientific body. Bishop Burnet, in his "History of his Own Times," calls Murray "the wisest and worthiest man of that age."

MURRAY, WILLIAM. See MANSFIELD.

MURRAY, WILLIAM VANS, an American diplomatist, born in Maryland about 1762, died

Dec. 11, 1808. In 1788 he went to London to study law, and while there published a pamphlet on the constitution and laws of the United States. In 1785 he returned to Maryland, practised law, was elected a member of the legislature, and served as representative in congress from 1791 to 1797. By Washington he was appointed minister to the Batavian republic, and afterward, in conjunction with Ellsworth and Davie, assisted in making the treaty between France and the United States, signed at Paris, Sept. 30, 1800. He returned to the Hague as resident minister, came back to this country in 1801, and passed the rest of his life in retirement at Cambridge, Md.

MUSÆUS. I. A Greek poet, who flourished at Athens in pre-historic times. He was said by some to have been a native of Thrace and a son of Orpheus; while others represented him as the son of Eumolpus and Selene, or of Antiphemus and Helena, and the disciple of Orpheus. He was regarded as the author of various compositions, especially of such as were connected with the rites of Ceres at Eleusis, over which he was thought to have at one period presided. According to a tradition preserved by Pausanias, the Museum at Piræus received its name from Musæus having been interred there. A few specimens of his reputed works are extant; but Pausanias deemed none of the productions ascribed to him genuine except a hymn to Ceres. II. A Greek grammarian, supposed by most modern critics to have lived at about the beginning of the 6th century A. D. He was the author of the poem on "The Loves of Hero and Leander," discovered in the 18th century. The best editions of it are those of Passow (Leipsic, 1810) and Schaefer (1825). It was jointly translated into English by Marlow and Chapman (1606), and there are several other English versions.

MUSÆUS, JOHANN KARL AUGUST, a German author, born in Jena in 1735, died in Weimar, Oct. 28, 1787. He studied theology, and was a candidate for a rural parish, but his services were declined on account of his having participated in a dance; upon which he renounced divinity, and accepted in 1768 an employment at the court of Weimar, as governor of the pages. He exchanged this office in 1770 for that of professor at the gymnasium of Weimar, which he held until his death. He wrote *Grandison der Zweite*, republished in 1781-'2 under the title of *Der Deutsche Grandison*, directed against Richardson's admirers. He also took the field against Lavater in his *Physiognomische Reisen*. His *Volkmärchen der Deutschen* (5 vols., 1782) gained a still wider popularity, which they retain to this day, and an illustrated edition was published at Leipsic in 1848. Kotzebue prepared an edition of his remains (Leipsic, 1791), with a biography of the author, whom he justly calls the good Musæus. Carlyle's "Specimens of German Romance" (London, 1827) contains admirable English versions of some of the most pleasing tales.

MUSCAT, the capital of Oman, and of the states of the imam or sultan of Muscat, situated near the E. angle of Arabia, at the head of a small inlet of the Indian ocean, near the entrance to the Persian gulf, in lat. $23^{\circ} 38' N.$, long. $58^{\circ} 42' E.$; pop. of the city and suburbs estimated at 60,000. The cove of Muscat, as the harbor is called, is about $\frac{1}{4}$ of a mile long, with half that breadth, opening to the N. W., and consequently completely sheltered from the prevailing winds or monsoons. To the W. of this inlet is a larger bay capable of affording shelter to shipping when the weather renders it difficult to enter the cove. The town stands on the S. side of the cove, in a hollow at the foot of cliffs 400 or 500 feet high, and shut in by high rocks from a view of the sea. It is built along the shore in the form of a horse shoe, and there is only one pass communicating with the interior. The hills are occupied by a circle of forts. Many of the houses are mere mat huts, and even those of the better class are only one story high. The sultan's palace is a plain edifice. The streets are so narrow that a few palm leaves laid across from house to house form a complete shade from the sun. The climate is excessively hot. The land breeze at night is suffocating, and the thermometer rarely falls below 90° in the shade. About 8 m. W. of Muscat and connected with it by a good road is the town of Mattra, nearly equal to it in population. Mattra has docks for building and repairing ships; and a large proportion of its population are engaged as fishermen, boatmen, sailors, and pilots. Sugar and coarse cloth are manufactured. There is an extensive transit trade with Arabia, Persia, and India. Cloth and corn are the principal imports, and their value amounts to about \$5,000,000 annually. The exports consist of dates, horses, salt fish, hides, and madder, which are sent to India; sharks' fins to China; and asses, &c., to Mauritius. The harbor abounds with fish, and the pearl fisheries are not far distant. The inhabitants of Muscat are of various races, Arabs, Persians, Hindoos, Syrians, Koords, Afghans, Beloochees, negroes, &c.; and the prevailing language is a kind of corrupt Hindostanee, the Arabic tongue being confined to the native Arabs.—Before the Portuguese found their way into the Indian ocean, Muscat was a place of considerable importance, and was subject to Ormus. Albuquerque took it in 1507, and it shortly became the centre of the Portuguese commerce in that part of the world. In 1648 the natives expelled the Portuguese, raised a strong maritime force, took possession of several places in the Persian gulf, and in 1707 obtained permission from the king of Pegu to build vessels in his territory. They constructed ships armed with from 30 to 50 guns, and committed great depredations upon the towns on the coast of Malabar and the Persian gulf, and upon vessels trading in the Indian ocean. During the latter part of the 18th cen-

tury they laid aside their piratical habits, and engaged largely in commerce; and after the accession of Said Seid in 1808, their territory has rapidly increased both in wealth and extent. This ruler was sultan of Oman, but was better known by his ecclesiastical title of imam of Muscat. The beginning of his reign was disturbed by pirates and Arab rebels; but the English East India company, in order to suppress piracy in those seas, joined the imam with a considerable force, and by 1823 his enemies both by sea and land were either subdued or driven into the interior of the country; so that, with the exception of the islands in his possession, his authority never extended much beyond the coast. In Asia the possessions of the imam of Muscat included the whole of the S. E. coast of Arabia, from the British settlement of Aden to Ras-el-Had, all the territory of Oman, nearly the whole of the coasts of the Persian gulf, the Bahrein islands, Ormus, and the coast of Mukran. In Africa nearly the whole of the territory extending between Cape Guardafui and Cape Delgado was tributary to him; and the fine islands of Socotra, Remba, Zanzibar, Mafea, &c., formed part of his dominions. The imam's rule, though despotic, was said to be just and liberal, and his subjects have made considerable progress in civilization. Traders enjoyed perfect security, and many foreign merchants from different parts of the world settled in his capital. In 1840 Said Seid removed his court and the seat of his government from Muscat to Zanzibar, and the island has since made rapid advances. The United States was the first power to appoint a consul at the new capital; the English followed their example in 1843, and the French in 1847. Several foreign commercial houses have been established, and the trade has proved exceedingly profitable. The revenue of the imam was derived from commerce, from import duties on foreign merchandise, and from tribute from dependent princes. He employed many vessels in commerce; and his naval force consisted of more than 70 sail of different sizes, a few of which carried 74 guns. Almost all the ships belonging to the imam and his subjects were built in British India, principally at Cochin, on the Malabar coast, and they are generally very fine vessels, many of them being 800 tons and upward. The officers are intelligent, and numbers of them understand navigation, and make successful voyages to China and different parts of the Indian archipelago. The imam had commercial treaties with the United States, with Great Britain, and with several other foreign powers. In 1840 he sent a present of valuable Arab horses and other articles, in one of his war vessels, to the president of the United States; and about the same time he presented a man-of-war, built of East India teak and complete in all respects except her armament, to the queen of Great Britain. In 1856 Said Seid paid a visit to Muscat, and died of dysentery on his return voyage,

about the end of the year. He left a numerous family, and his son Majed succeeded him as sultan of Zanzibar and ruler of the African dominions, while another son has established himself at Muscat and assumed the sovereignty of the Asiatic provinces.

MUSCATINE, a S. E. co. of Iowa, bordering on Ill., from which it is separated by the Mississippi river, and intersected by Red Cedar river; area, 440 sq. m.; pop. in 1859, 15,503. It has a diversified surface and fertile soil, and contains extensive beds of coal and quarries of freestone and limestone. The productions in 1859 were 561,703 bushels of Indian corn, 154,608 of wheat, 17,580 of oats, 57,297 of potatoes, 10,872 tons of hay, 8,066 gals. of sorghum molasses, and 260,111 lbs. of butter. The value of general manufactures in that year was \$696,194.—MUSCATINE, capital of the above co., on the Mississippi, at the apex of the "great bend," in the midst of a series of picturesque bluffs, 100 m. above Keokuk, and 82 m. S. E. from Iowa City; pop. in 1856, estimated at 9,000. It is the centre of a large and increasing trade, and the river landing is very good, with space for improvements in levees. In 1856 there were 3 steam flour mills, with a capital of \$148,000, 3 steam saw mills, 2 planing mills, several manufactories, a large variety of stores, and 16 churches and religious societies. The annual sale of lumber exceeds 10,000,000 feet. It is connected with an extensive network of railroads.

MUSCLE (Lat. *musculus*), a term applied to the fibrous contractile tissue forming the flesh of man and animals, by which locomotion and the various functions of life requiring voluntary or involuntary movements are performed. Whether elongated in shape or enclosing a cavity, this tissue is arranged in the form of fibres, usually in bundles connected by areolar tissue, surrounded by a vascular network, and supplied with nervous filaments. Muscles are so arranged as to produce great velocity, extent of motion, and strength, without injuring the beauty of proportions, by the obliquity of their fibres to the tendons and of the last to the bones on which they act, and by the proximity of their points of insertion to the axis of motion of the joints. Muscle is attached to bone by means of tendons, rounded or flattened fibrous cords, white and shining, and very resisting; aponeuroses or fasciæ are firm, shining fibrous membranes, enveloping the muscles, giving attachment to their fibres, and fixed often to bones like the tendons. Muscle occupies the whole distance between the skin and the bones, and takes an elongated, broad, or thin form, according to the necessities of the several parts of the body; its strength is in proportion to the length and thickness, and may be rapidly exhausted by continuous exertion. Muscles are called voluntary or involuntary, according as they are or are not under the control of the will; the division is not strictly accurate, as all of the former at times contract independently of the will, and many of the latter are to a certain

extent under the influence of volition. The former are generally solid, as the ordinary muscles of motion, and the latter hollow, as in the heart or the muscles surrounding cavities and canals; the former are striped crosswise with very delicate and close parallel lines, which, with a few important exceptions, are not found in the latter; the most marked of these exceptions is the heart, which is composed of striated fibres; the upper portion of the muscular coat of the œsophagus, though the will has no power over its movements, displays the same striped character. As the structural differences between these two kinds of muscle are constant and easily perceived, and seem to have certain relations to the varying activity and mode of exercise, it is convenient to preserve this distinction. The length of human muscular fibre varies from more than 2 feet in the *sartorius* to not more than 3 lines in others. The diameter in the uncontracted state, according to Mr. Bowman, averages in man $\frac{1}{16}$ of an inch, in woman $\frac{1}{18}$, in other mammals $\frac{1}{16}$, in birds $\frac{1}{16}$, in reptiles $\frac{1}{16}$, in fishes $\frac{1}{16}$, and in insects $\frac{1}{16}$; but in all the classes there is considerable variation in the same animal and even in the same muscle; the fibres of the heart are generally smaller than in other striped muscle. The form of the fibre is more or less cylindrical, sometimes flattened or irregularly polygonal; the color depends on that of its elements and on the blood in its vessels, varying from white in crustaceans and most fishes and reptiles to the red of the higher animals, and the very dark of the pectorals of some birds. Each fibre of voluntary muscle, according to Mr. Bowman, will separate into thin disks in the transverse striated lines, and also into fibrillæ by longitudinal division; the former are most evident in some fishes (as the eel), while the latter are best seen in man and mammals. A disk or fibrilla is made up of primitive particles or sarcoelements, minute portions of muscular substance or myoline surrounded by a thin cell wall, like so many beads; these particles do not vary much in size and shape in all animals and at all ages, and are from $\frac{1}{16}$ to $\frac{1}{16}$ of an inch in diameter; in these the contractile power is believed to reside. According to Dr. Barry, the flat filament or fibrilla consists of 2 spiral threads side by side, with their coils interlocking. The elementary fibres contain among the primitive particles corpuscles or nuclei of the original cell structure, of the average diameter of $\frac{1}{16}$ of an inch; every fasciculus or series of fibres is invested with a tube of very thin but tough and elastic membrane, the *sarcolemma*; this isolates and protects the contractile tissue, facilitates the motions of contiguous fibres, and perhaps serves to conduct the nervous influence among them; each fibre at its extremity is attached to fibrous tissue. The unstriped elementary fibres, or those of organic life, are soft, pale, flattened bands, apparently homogeneous, from $\frac{1}{16}$ to $\frac{1}{16}$ of an inch in diameter, with frequent

prominences occasioned by the elongated corpuscles; the existence of a sarcolemma in these is doubtful. A good example of this kind of muscle is seen in the circular fibres of the intestines, where it is uncertain whether they are parts of circles, circular, or even spiral. The fixed point of a muscle is called its origin, and the movable one its insertion; the capillaries of muscle may be easily injected and be seen running in parallel lines between the fasciculi, giving off transverse connecting branches; its nerves end in loops, returning into each other. As a general rule, the striped fibre is found in all the voluntary muscles, and in some involuntary (as in the constrictors of the pharynx, beside those above named); voluntary muscles are those put or retained in action by the will through the instrumentality of the cerebro-spinal system of nerves; those presiding over the acts of swallowing, breathing, and genito-urinary functions, are only partially under the control of the will. The unstriped fibre occurs in the muscular apparatus of organic life, whose activity is but little dependent on nervous agency, and that little derived from the sympathetic system; here belong the muscular coat of the alimentary, respiratory, and genito-urinary passages, of the ducts of the glands, of the blood vessels, and the dartos. Striped fibres have been found in all vertebrates and in articulates; as we descend the animal scale the movements become more and more automatic, until complex muscular action gives place to simple ciliary vibration. The contractility of muscle depends on an inherent property, independent of, though capable of modification by, nervous influence; contractility and development are proportionate to each other, showing the connection of the former with the condition of nutrition and not with the influence of the spinal cord. The stimuli which induce contraction are volition, emotion, impressions conveyed to the nervous centres and involuntarily reflected thence, and various physical and chemical agents applied to any portion of the course of a motor nerve or to the muscular fibres. A muscle in action becomes shorter and thicker, changing its relative proportions without any actual change in bulk; after death muscles become stiff from contraction, constituting the *rigor mortis*; all muscles have a power of passive contraction or tonicity from the very nature of the tissue, and by this they are brought into a state of equilibrium during sleep, this power ceasing with life. In the active contractions which characterize muscle on the application of stimuli, force is exerted against some opposing power; this is attended with more or less exhaustion or fatigue, and requires intervals of rest; sustained contraction consists of an infinite number of partial momentary contractions acting in succession. To show the wonderful power of adaptation which the ordinary acts of life require, it may be stated that there are in the human body 527 distinct muscles, of which 261

are in pairs, and 5 single on the median line; of these there are in the head and face 83, the *orbicularis oris* being single; in the neck 49, the arytenoid of the larynx being single; in the thorax 78, the *triangularis sterni* and the diaphragm being single; in the abdomen 88, the *sphincter ani* being single; in the back 78; in the upper extremities 98, and in the lower 108. Yet, with all this complex apparatus, every thing is in perfect order and harmony. Matteucci and Du Bois-Reymond have investigated the electric currents of muscles; for the interesting details therewith connected, both physiological and pathological, the reader is referred to recent works on physiology. The combination of the muscular movements is in most cases so far independent of the will, that we are apt to lose sight of their perfection; but let paralysis affect one side of the body or contraction draw up a muscle, and the fact becomes at once evident, as may be every day seen in palsy of one side of the face, or strabismus with the turning in or out of the eye; the simple process of walking, performed it may be unconsciously, with its nice adjustments executed for us by the automatic guidance of the senses rather than by any act of the will, is what the most ingenious mechanician can never effect in an automaton, from the impossibility of harmonizing the many acts which constitute walking. The energy and rapidity of muscular contraction is more remarkable in the lower animals than in man. The muscular power of insects is seen in the rapid flight of the dragon fly, the leap of the flea and the cricket, the fixed attitudes of some larvæ, and the strength of beetles. It is very great in the flight of birds, though their whole structure is organized for aerial motion; the power of the wings is 8 times as great as that of the legs in ordinary birds, and their absolute power in proportion to the weight of the body as 10,000 to 1; in small birds the movements of the wings are so rapid that they cannot be counted by the eye; the muscular force of the hawk can propel it 150 miles an hour, and the albatross can fly across the ocean without fatigue. Dragons, flying fish, phalangiers, and squirrels (pteromys), though well organized in some respects for aerial progression, cannot fly for want of sufficient muscular power; but the extinct pterodactyle and the existing bats show extensive powers of flight. The amount of muscular force necessary for flight is so great, that if man could concentrate all the strength employed in a day's labor, he could not support himself in the air for more than 5 minutes; the accomplishment of flight in man, even with the assistance of mechanical contrivance, may be safely considered an impossibility. The energy of the muscular system of fishes, considering the rapidity with which they move in their dense medium, must be very great. Other familiar examples of muscular power are seen in the contractions of the boas; the leap of the frog, kangaroo, jerboa, and hare; the speed of the

antelope; the spring of the lion; and the strength of the ox and elephant. The muscular power of man is more advantageously displayed by the extent of motion than by actual force; but by scientific training great strength may be obtained from naturally feeble persons. The rapidity of muscular action is familiarly seen in the ventricular contractions of the child's heart, each of which occupies about $\frac{1}{3}$ of a second; in the movements of the vocal cords in rapid singing or speech; and most remarkably in the flight of insects, whose wings strike the air sometimes thousands of times in a second, by a muscular mechanism and arrangement of elements mentioned under GRAT. Every muscular act involves an interstitial change, a disintegration of this tissue and its re-formation from the constant supply of blood to the parts specially active. Muscle may be hypertrophied from excess of nutrition arising from abundance of formative material, from increased supply of blood, but principally from preternatural formative capacity; the opposite conditions lead to atrophy of muscle. A remarkable change in muscle consists in its fatty degeneration to which the fibres of the heart are very subject; the muscles of the limbs after paralysis are occasionally thus affected. Throughout the animal kingdom the development of the muscular system is in conformity with that of the nervous system. The vertebral system of muscles is most developed in fishes; the costal in serpents; the hyoid in fishes; those of the limbs inversely as those of the spine, feeblest in fishes; the masticatory in vertebrates; the tegumentary in those mammals armed with spines (like the hedgehog and porcupine), and in the unpaired or vertical fins of fishes; those of the voice in birds, mammals, and man; the diaphragm in mammals only. The muscles of the hand reach their highest perfection in man, while those of the tongue, eyes, ears, and nose show that many systems are most complete in the lower mammals, existing in man only in a comparatively rudimentary condition.

MUSCLE SHOALS. See TENNESSEE RIVER.

MUSCOGEE, a W. co. of Ga., separated from Alabama by the Chattahoochee river, and bounded E. and S. E. by Upatoi creek; area estimated at 200 sq. m.; pop. in 1859, 15,072, of whom 6,800 were slaves. The county was divided subsequently to the U. S. census of 1850. It is intersected by the Muscogee railroad, which has its terminus at the capital, Columbus.

MUSCOVY. See RUSSIA.

MUSCOVY DUCK. See DUCK, vol. vi. p. 45.

MUSES (Gr. *Μοῦσαι*, from *μα*, to strive, to conceive), in classical mythology, the goddesses originally of song, and afterward of all kinds of poetry and of the arts and sciences. From the time of the earliest legends they had their principal seats in Pieria on Mt. Olympus and in Boeotia on Mt. Helicon. Homer styles them the *Olympian*, and Hesiod the *Heliconian*; according to the latter, however, they were born on *Olympus*, and dwelt at a short distance from the pinnacle on which Jupiter was enthroned,

whence they visited Helicon to bathe in Hippocrene, and celebrate their choral dances around the altar on the top of the mountain. Müller infers, from the fact that the worship of the Muses originally flourished on the same mountain which was represented as the common abode of the gods, that it was the poets of that region, the ancient Pierian minstrels, whose imagination created and arranged the Olympian council. Elsewhere they were chiefly honored as the nymphs of fountains. They were commonly esteemed the daughters of Jupiter and Mnemosyne; but were also called daughters of Cœlus and Terra, of Pierus and a Pimpleian nymph, of Jupiter and either Plusia, Moneta, or Minerva, of Apollo and Plusia, and of Æther and Terra. Their number was variously given at first, either 3, 4, or 7, but was at length established and recognized as 9 throughout Greece. Hesiod first states the names of all the 9, by which they are usually designated: Olio, the muse of history; Euterpe, of lyric poetry; Thalia, of comedy; Melpomene, of tragedy; Terpsichore, of choral dance and song; Erato, of erotic poetry; Polyhymnia, of the sublime hymn; Urania, of astronomy; and Calliope, of epic poetry. In Homer as in later authors they sing festive songs at the banquets of the gods, and are invoked by mortal poets to bring before the mind the events which they have to relate, and to confer the gift of poetry. They punished Thamyris, who had presumed to excel them, with blindness; stripped the sirens, who had ventured on a contest with them, of their wings; and metamorphosed the 9 daughters of Pierus, who sought to rival them, into birds. Though usually regarded as virgin divinities, the greatest mythical bards, such as Linus and Orpheus, were called their sons. Apollo, as the god of the lyre, led their choir, and they themselves had the gift of prophecy. They were worshipped with libations of water or milk and honey, received various designations from the poets according to the places that were sacred to them, and were represented each with particular attributes in works of art.

MUSEUM (Gr. *μῦσεον*, a temple of the Muses), a building or room devoted to the collection and preservation of rare and interesting objects in nature and art; or more properly perhaps the collection itself. The name is said to have been originally applied by Ptolemy Philadelphus to that part of his palace in Alexandria which he set apart for the promotion of learning and the support of learned men. More in accordance with the modern idea of the term were the celebrated temples of Apollo at Delphi, of Juno at Samos, or the acropolis at Athens, stored with the choicest works of art, and with consecrated gifts of immense value, by generations of pious devotees. When the Greeks had succumbed to the power of ruder races, these edifices were despoiled of their chief treasures, which were accumulated by the successors of Alexander and the Roman emperors in their capitals, more for the purpose of adding to the

splendor of triumphal pageants, or as evidences of far-reaching conquests, than from a desire to found collections of works of art. It was in this spirit doubtless that Nero ordered 500 statues to be sent from Delphi to ornament his "golden house." In later ages the irruption of barbarian hordes into the ancient seats of civilization involved the existing works of art in a common destruction. Rome, which had despoiled so many conquered provinces, suffered herself to such an extent, that, at the period of the renaissance or new birth of art, of all her vast collections but a few antique bronzes and statues were known to be in existence. With the awakening taste for art arose a desire to collect the relics of civilization of earlier ages; and to Cosmo the Great of Florence, who laid the foundation of the famous Florentine museum, is due the conception of the museum in its modern signification. His example was followed by other eminent men in Italy, and Pope Leo X., a member of the house of Medici, with many of the Roman nobility, adorned their palaces and villas with antique ornaments, coins, and statuary, procured principally by excavation. The spirit of emulation which this new taste excited among the great Italian families made their residences at first the richest depositories of art, and it was only by degrees that public museums assumed the character of completeness, symmetry, and judicious arrangement which they now present. The mania for collecting was during the 16th and 17th centuries carried to such an excess, that, for the purpose of enriching capital cities, outlying provinces were stripped of their choicest works of art, which were crowded together with so little regard to taste, that the buildings appropriated to their reception savored more of the modern curiosity shop than the museum. With the present century a better system of arrangement has come into vogue, and the contents of the great European museums are now disposed in situations corresponding to their character, and with due regard to their effect upon the spectator. These contents, from being devoted exclusively to the remains of antiquity, now embrace works in every department of modern or contemporary art, and vast collections of rare and valuable natural productions. The latter, from their practical character and importance in aiding the development of natural science, have gradually been formed into distinct museums of anatomy, geology, zoology, botany, and the other great branches of physical knowledge which modern researches have so greatly augmented and developed.—In Italy, the earliest seat of modern art, the most celebrated museums are the Vatican at Rome, the Florentine museum, and the Museo Borbonico at Naples, all filled with choice pictures, statuary, and remains of ancient art. Turin, Modena, and other Italian cities possess institutions similar in character, but of less extent or value; and here, as elsewhere in Europe, galleries of

pictures are considered as coming within the meaning of the term museum. The principal cities of Germany vie with those of Italy in the richness and completeness of their collections of the products of art, Berlin, Vienna, Munich, and Dresden being particularly distinguished in this respect. In Gotha, Weimar, Nuremberg, Cassel, Darmstadt, Bonn, Frankfurt-on-the-Main, Stuttgart, Breslau, Prague, Cologne, and in other cities, the museums are well appointed and intelligently arranged. The most extensive one in eastern Europe is that of St. Petersburg, which, although of comparatively recent formation, is already one of the richest in the world. The collections of Odessa and Kertsch, the latter of which was considerably damaged during the war in the Crimea, are also deserving of notice. France possesses in its Louvre and Luxembourg palaces in Paris, two of the noblest collections of pictures, sculpture, antiquities, and other objects of art ever made. Other interesting collections of objects of art and nature are contained in the same city, including the museums of comparative anatomy, zoology, &c., at the *jardin des plantes*, as also in Rouen, Grenoble, Orleans, Lyons, and the chief French cities. Denmark has its Thorwaldsen museum in Copenhagen, remarkable for its collection of the works of that artist; and in Stockholm, Amsterdam, Antwerp, Brussels, Ghent, Madrid, Lisbon, and elsewhere in continental Europe, are museums of pictures of considerable value, which, as in the case of the institutions already mentioned, will be found more particularly described under the names of the places where they are established; in the more prominent instances, as the British museum, the Vatican, and the Louvre, they are described under their own names. The Ashmolean museum in Oxford, founded by Elias Ashmole in 1679, is the most ancient in England, but is overshadowed in importance by the British museum in London, an institution unsurpassed in its literary treasures and costly relics of antiquity. In the United States the term museum has been applied to buildings of a public character, containing a heterogeneous collection of objects, animate as well as inanimate, and which are in some instances used also for theatrical performances. The museum of natural history in Philadelphia, particularly rich in its ornithological department, and the collections illustrating the manners and productions of various races and countries deposited in the Smithsonian institution and other public buildings in Washington, are more worthy of the name. In 1859-'60, chiefly through the efforts of Professor Agassiz, a museum of comparative zoology, designed on a very comprehensive scale, was established in Boston, and promises to become very interesting and valuable.

MUSHROOM, the name applied to some of the species of *agaricus*, which are more particularly used for food. Of these the common mushroom (*A. campestris*, Linn.) is considered

to be the most nutritious, and is used extensively wherever it can be found; it is the one preferred in preparing a sauce known as ketchup. The common mushroom belongs to the natural order of *fungi*, most species of which are poisonous, and fatal consequences have resulted from not knowing how to distinguish the few which are valuable from the majority which are dangerous. The mycelium of the mushroom consists of white, cottony threads, running horizontally just below the surface of the ground, and serves in some way for the nutrition of the rest of the plant. From this arise at the proper season of the year several small knobs, which increase in size until they penetrate the soil above; these do not however appear simultaneously, but are projected at periods during several weeks, whenever the state of the weather is favorable. When one of them has broken the surface, it comes up with a convex top, and in this stage of growth it is called the button. In a few hours the button spreads out horizontally, and the flattened part is called the *pileus*. Intermediate between the ground and the lower surface of the pileus is the stem or stipe; if this be broken across, it will be seen to have considerable firmness of consistence and to be of a prevailing white color. Just below the pileus is the *annulus* or ring surrounding the stipe, its origin being the lower edge of the pileus separated from the envelope (*velva*) of the button condition of the plant by being torn across in the upward growth of the stipe. The under side of the pileus is furnished with numerous folds, the *hymenium*, the alternate ones of which are shorter than the others. These folds are sometimes called the gills, and upon their surfaces are borne innumerable dust-like particles, which are the spores or seeds. The upper surface of the pileus is dry, whitish, silky, or becoming scaly by the peeling of the epidermis into fragments, whose edges are slightly curled up; the odor of the pileus is pleasant. The mushroom is gathered when the gills are of a rosy pink color, though some prefer to gather it when in the button condition. As the mushroom begins to decay and perish, the gills are of a very dark brown color, and the plant is unfit for food. This species grows in old pastures where horses and neat cattle usually feed. It is much cultivated in Europe for a table delicacy. The mycelium is collected, mixed with dung and clay or mould, in which the spawn rapidly diffuses itself; the mass is then broken into small pieces and planted in beds prepared for its cultivation. The vitality of the mycelium is such that dryness for a long time does not seem prejudicial. Some mushroom growers prefer to search for the mycelium and transfer it fresh to their mushroom beds. Sometimes pieces of the gills are soaked in water for 5 or 6 days, and the infusion containing the spores is sprinkled over the beds for the purpose of raising a crop from the seed.—The champignon (*A. oreades*, Bolton)

has a tough, fleshy pileus, at first pale brown, becoming whiter with age; the gills are whitish; the stipe round, whitish, with a skin which separates into longitudinal fibres; it has no ring. The qualities of this species, according to Lindley, are fragrant, stimulant, and nutritious. It occurs in the pastures and lawns of England, where it grows in irregular circles, and forms what are called fairy rings. When dried in the shade after being strung upon threads, the mushrooms are pounded and form an addition to rich sauces. The peppery mushroom (*A. piperatus*, Scopoli) has a short, thick, smooth stipe, and a pileus 4 to 6 inches broad, which is dry, pale yellow, with a deflexed margin, but curled inward when young; the gills are numerous, very narrow, linear, not quite straight, and repeatedly forked. It emits, when broken, an abundance of pungent, milky fluid. It occurs in woods in the months of September and October, and is considered edible, the pungent and acrid juice being lost in its preparation for food.—There are other species which are eaten, but considered dangerous, the milky-juiced ones especially; and unpleasant and fatal effects have followed from their use. The common mushroom (*A. campestris*) is the one preferred for food both in Europe and America, the two others being found likewise in the United States.

MUSIC (Gr. *μουσα*, a muse), one of the fine arts, the elements of which are melodious and harmonious sounds. Musical sounds arise from equal vibrations of the air set in motion by whatever cause. These vibrations are palpable in the strings of a piano, and in the tremblings of the organ loft when the deep pedal notes are sounded. (See HARMONY.) When these sounds are deep or grave, the vibrations are comparatively few; when high or acute, they are many. For example: an appreciable musical sound is the lowest note of a great organ; this gives some 33 vibrations to a second of time; the highest note, however, affords some thousands of vibrations to a second. (For the means by which this most remarkable and subtle analysis of vibrations is established, see Ohladni's "Acoustics.") Ideally there is no limit to the pitch or extent of sounds, but practically for the purposes of art such a limit exists. It is found in the human voice, which is the most perfect and the most expressive of musical instruments, and which in singing ranges from a note represented at E flat below the line in the base clef to E flat above the line in the treble clef, of the 5 parallel lines used for modern musical notation. A sound lower or higher than this is hardly capable of expressing a vocal sentiment. This extent includes the lowest note of the masculine voice and the highest of the feminine. Voices may be considered under 6 divisions, 3 masculine and 3 feminine, though there are exceptional instances where the extent of the voice supercedes to some degree such exact arrangements. The usual range of each of these voices is two octaves, though

some have a greater and many a smaller compass. The deepest, and accordingly most manly voice, is the base commencing on or about F or E below the line of the base clef, sometimes a shade lower. The baritone voice is a less heavy masculine voice, commencing on or about G on the first line of the base clef. The tenor voice is the least robust but generally most tenderly toned of the masculine voices, and begins on or about B flat or C, as may be represented severally on the second line and space of the base clef. These voices are very distinct in their characteristics. The deepest feminine voice is the contralto, the lowest notes of which are represented in musical notation as an octave above the base. The second or mezzo soprano voice is rendered in notation an octave above the baritone. The soprano is notated an octave above the tenor.—Instrumental music possesses value and beauty just in proportion as it resembles the voice. The instruments in the orchestra, though far inferior in quality to the best voices, are with hardly an exception capable of greater range. Their scope is imitated from the human voice. Of the stringed instruments, the largest gives the deepest note, it being a law that profundity of tone is in the ratio of size. The same rule holds for the wind instruments, increased volume augmenting depth, and the contrary. The most comprehensive instruments as to extent are the great organ and the pianoforte; these give all and more than the low and high notes found on all the instruments used in the orchestra, viz.: the violin, viola, violoncello, and double bass; and the octave flute, large flute, hautboy, clarinet, bassoon, trumpet, horns, trombones, tubas, and kettle drums.—The octave in music derives its name from the fact that the natural scale of music, after giving from any key note or radical point of departure 7 distinct tones, reproduces the original note in a less grave manner—an identity, yet with a difference, if a paradox may be used. Nature asserts this reiteration to the ear; and the poetical beauty of the fact is indefinitely heightened when we reflect that the difference of the masculine and feminine voices, as expressed severally in the strength of manly or the sweetness of womanly tones, is measured by octaves. As the original note is so produced at every 8th interval, the names of the notes are simply repeated again and again for each new scale of 7 notes. Hence 7 signs, A, B, C, D, E, F, G in English, or *la, si, do, mi, re, fa, sol* in Italian, represent all the scales. Octaves coalesce so perfectly, that any passage or tune sung at one pitch can be given at the same time effectively and properly at octaves above or below it. Hence an air sung by a base voice may be rendered simultaneously by the tenor or contralto at one octave above, and the soprano two octaves. In instrumental music a passage or air may be played thus on 5 or 6 octaves at the same moment. The notes which lie closest together or at the interval of a second are the

least harmonious, and, except when scientifically treated, affect the ear unpleasantly. The harmony of the interval of the third is perfect. Take a key note, add one major third, and then another, a minor third or a half tone less in extent than the major, and there occurs the perfect major chord of 3 notes, called the tonic or key note, the mediant or third, and the dominant or fifth; this chord is the root of the large and expressive scheme of harmonies. The scale of 7 notes with the octave includes two degrees, half the extent of others; nature therefore recognizes the half tone. The scale accordingly is thus divided: 1st to 2d interval, a tone; 2d to 3d, a tone; 3d to 4th, a half tone; 4th to 5th, a tone; 5th to 6th, a tone; 6th to 7th, a tone; 7th to 8th, a half tone. Art next has divided the whole tones of the scale, which are 5, into halves, and this, with the two half tones of the natural scale, gives the chromatic scale of 12 half tones. The minor scale is found a third below the major, and differs from the major in lowering the third a half tone, and raising a half tone, under certain conditions, the 7th of the scale.—Musical notation, or the expression of musical ideas by means of certain conventional signs, has undergone many changes in Europe, and the present system is the result of a long series of improvements. The ancients had ways of writing music which are now very imperfectly or not at all understood. The oldest legible notation of Christendom is on 3 or 4 parallel lines, the notes being square or angular and variously colored. The melodies are not divided into measures by bars, though the notes are of different lengths. This old system is preserved, with slight modifications, in the plain chant of the Roman Catholic church, and may be seen even in the missals, vesperals, and graduals which issue from the modern press. The notes are square and diamond-shaped, and are written on a staff of 4 lines. A bar is used at the end of every word. The signs now employed in music denote the length, pitch, and force of tones, or rhythm, melody, and expression. The length of a note is represented by its shape. The notes are the breve  or , semibreve , minim , crotchet

, quaver , semiquaver , demisemiquaver , and demiquaver , but the first and last of these

are little used. The breve is twice as long as the semibreve, the semibreve twice as long as the minim, and so on. A dot following a note lengthens it one half, thus, . Rests,

indicating silence, are: , equal in length to , or a whole bar;  = ;  = ;  = . Rhythm is further

marked by the division of time into measures of equal length indicated by vertical lines or bars drawn across the staff. Measures again are divided into 2, 3, 4, or 6 parts, and the first part of a measure is almost always accented. There are 4 measures in common use: double, triple, quadruple or common, with a secondary accent on the 8d part, and sextuple with a secondary accent on the 4th part, each represented by figures placed at the beginning of the staff, as follows:

Thus, taking the crotchet as a standard, in double time there must be 2 crotchets or their equivalent in every bar or measure, in triple 3, in quadruple 4, in sextuple 6. There are exceptions to these rules, however, and even 5 crotchets to a bar have been used with eccentric effect.—The pitch of a tone is determined by its position on the staff, which consists of 5 parallel lines and the 4 intervening spaces, and by the clef, which indicates the pitch of all the notes on one line or space of the staff, whence the rest are easily found. In the early Italian school every kind of voice had its own clef, but at present only

two are in general use, the treble or G clef of the violin, , and the base or F clef,

. In some musical scores, however, particularly Italian, the C clef is retained for the tenor and alto parts. For the former it is placed

on the 4th line, , which thus becomes

the position of C, and for the latter on the 8d,

The popular plan in writing music

in 4 parts is to put the alto on the same staff with the treble, and the tenor with the base or treble. With these staves, and the aid of short lines called leger lines placed above and below the staves, we are able to represent all the notes of the human voice, and even more. The following is the musical scale from the lowest note of the base voice to the highest of the soprano:

The pitch of any note may be raised half a tone by means of a sharp (#) placed before it, or lowered half a tone by a flat (b). When a sharp or flat is placed on a line or space at the beginning of a staff, it affects every note occurring on that line or space and its octaves throughout the piece. A natural (n) restores to its normal pitch a note affected by a flat or sharp. A note or passage may be raised or lowered an octave by writing over or under it the sign 8va. ----- . Beside the words *forte*, *fortissimo*, *piano*, *pianissimo*, and their abbreviations, *f.*, *ff.*, *p.*, *pp.*, indicating that a note or passage is to be given loud, very loud, soft, or very soft, there are the signs < (*crescendo*), denoting a tone gradually increasing from soft to loud; > (*diminuendo*), the reverse of crescendo; > (*sforzando*), an explosive

tone instantaneously diminished; 

(*staccato*), a short articulate utterance as if each

note were followed by a brief rest; and 

(*legato*), a binding together of successive tones.

Several attempts have been made to substitute letters and other signs for the notation now in use, but it seems too fixed to admit of change; and after all, the notation is the least of the difficulties which a learner of music has to overcome.—The music of nature suggested that of art. Melody and harmony are both found in the music of nature. Melody is the sequence of single sounds rendered by a single voice or instrument. Harmony is the combination of two or more notes sung or played at the same moment. The conditions of good melody require brevity; and, as a rule, a possible alliance with measured poetry and its pauses and punctuations, must underlie every melody which aspires to the dignity of vocal beauty, whether words be set to it or not. Of lines, 8, 12, or 16, seldom more than the last, suffice for a melody. For some reason, melody, which is divided into measures of equal length to make it agreeable or memorable, shrinks from rhythms of 8 or 5 measures, and demands those of 2, 4, 6, and 8. Accordingly, words set to melody are ranged thus: the 1st line of poetry requires two measures of music, the 2d two, the 8d two, the 4th two. If the symmetry of the poetical quatrain be observed, the melody in so far is correct.

But 4 lines are too brief; so a 2d or 8d quatrains gives a 2d or 8d part to the melody. Extra lines inserted, or shorter lines, give piquancy to it. Melodies, especially of the Italian school, often present the same notes, with hardly a variation, for the 5th, 6th, and 7th measures, with the 1st, 2d, and 8d. On the 4th measure, answering to the end of the 2d line of poetry, there occurs generally a semi-cadence, answering to a semi-colon; but the close of the 8th bar answers generally to a full point. Hence it is evident that symmetrical poetry is intimately connected with music; and in the contracted musical system of the ancient Greeks, poetry and music were inseparable, and were always taught together. As in poetry there are syllables of different lengths, so in music there are notes of different lengths, and to a much greater point of diversity; for what would be a drawl in speaking may form one of the chief attractions of music, namely, prolonged notes. The composer accordingly varies constantly the length of his notes. Monotony is fatal to a melody; hence changes from one note to another must be constant. The more brilliant melodies, the bravura airs of operas, especially those for the feminine voice, extend over a wider range than songs for the drawing room or popular use. The latter generally do not employ more than 8 or 10 notes. The popular air of "The Last Rose of Summer" is on 8 notes; the "Star-Spangled Banner" extends to 12. A melody presupposes harmony; and a very few chords will accommodate any melody, though the composer may choose, for the purposes of coloring, and determining deeper meanings, to multiply his chords. The beauty of melody determines the development of the art.—The earliest MSS. capable of being deciphered which we have of European music are about 800 years old. The melodies of that day were such as ignorance of the resources of the voice, the varieties of length and pitch of notes, of the symmetries of cadence, and the splendors of modulation from one key to another, might suggest. They were feeble dawnings of musical light. Among these old MSS. some odes of Horace appear, and it may be conjectured were such as were sung after dinner in the poet's day. They may be described as musical declamation, but not melody as we understand it. It is generally conceded that the Greeks did not understand harmony, and that their lyre of a few strings merely played the notes of the voice. The discovery of some Greek musical MSS.—that is, poetry with musical signs—upon the revival of letters, gave rise to a great amount of erudition and passionate argument. Fanaticism in favor of Greek music culminated, but all to no purpose; for no satisfactory key to the Greek system was found. Although a treatise on ancient music by Euclid is extant, and other writers of antiquity who have come down to us discuss it, yet they shed little light on the ancient musical MSS. We know that the Greeks had many hundreds of musical signs; that to be a musician-poet

required years of practice; but with the interpretations of the two or three extant Greek musical MSS., we can only discover, if the interpretations be right, that they had some sort of a minor mode, and declaimed in a kind of recitative, and intoned pretty much as is done in the Roman Catholic service by the priest. Religious, patriotic, or erotic poetry, so intoned or musically declaimed before a people of such lively imaginations as the Greeks, may easily have produced the effects ascribed to it by poets and historians; but it was the sentiment, and not the value of the melody. The Greek lyre was too poor an instrument to afford much melody, though the ancient flute might have had some advantages; but as there was a theocratic resistance to improvements in instruments, and the maintenance of music in prescribed forms was considered a state necessity, we may fairly infer that the science of music was not understood by the ancients. Indeed, it may be affirmed that without either the great organ or the piano-forte, the science of harmony could not have been created. Through these instruments the analysis of chords, the relations of keys, the intercourse in its fulness of melody and harmony, were established, and melody was developed to its present perfection. A Latin MS. of the 10th century gives evidence of some progress toward an understanding of harmony, and lays down certain rules which are at least interesting as showing what the theory of harmony was then. Some of these rules however are incorrect, and others want clearness.—As the church organ improved, we find harmony taking a wider and bolder range, and the genius of Palestrina especially imparted to the combinations of sounds meanings subsequently so improved upon and intensified. His theory of chords was chiefly plain processions of those found on the intervals of the scale, and a liberal use of what is technically called suspension, or holding a note of a chord over into the next chord before it settles on its appropriate place. In modern harmony there are 18 principal chords, derived from 8 which may be considered generic. Of these 18, 4 are called chords of the fifth, each being composed of 3 notes, namely, a first, third, and fifth, and called the major, minor, diminished, and augmented; 4 chords, composed each of 4 notes, and called chords of the seventh; 2 called ninths, major and minor, composed of 5 notes, the greatest number which a chord can contain without sacrifice of clearness; the augmented sixth; the augmented sixth with the fourth; and the augmented fifth with the seventh. Chords may be given incomplete, that is, with fewer notes than their entire number. They are varied thus: As there are 12 half tones on the scales, the chords may be given on 12 different keys or tonics. These keys are further duplicated by being changed into the minor scale. The suspension which we have described may alter and vary some of the chords, though others are sufficiently dissonant without; for it must be observed that

of the 18 chords, only the 2 first of the list, the perfect major and minor, are consonant; and hence upon them alone can a strain or piece be completed. The others are more or less dissonant, and require to be resolved sooner or later in the course of their treatment upon the consonant major or minor. The appoggiatura, or a note a single interval above or below any note regularly in chord, struck simultaneously with the chord, varies it. A note suspended does the same. The suspension requires a note to be heard in one chord before it proceeds over to another; an appoggiatura requires no such preparation. Variety in chords is further secured by inversion; that is to say, every chord has its fundamental base note; but if, instead of putting this base note beneath, another note in the chord is so placed, the chord is said to be inverted. For example: the chord C E G is on its fundamental base, the C being lowest; but if E be placed below, so that it is given E C G or E G C, it is said to be on its first inversion; or if it be rendered G C E or G E C, it is said to be on its second inversion. Whenever music is written for parts, the laws of harmony necessarily come into play, and the skill of the composer is required, not only to have the harmonies correct, but that the parts shall be distinct and clear. This polyphonic style requires laws of a very intricate character, and hence persons capable of creating lovely melodies, and writing them in combination with other themes, are as rare as great poets. In harmonious treatment of music, the following are a few of the radical laws. In the regular progression of harmonies the fundamental base note falls a fifth to whatever note, or rises a fourth to the octave above it; but this law has many exceptions. If in the treble or soprano part the procession of notes is upward, say C D E G, the base cannot give the same notes, but must use others, such iterations being intolerable to the musical ear. Accordingly, it is a rule in harmony or part writing that contrary motion is best between the extreme parts; or that when one goes upward the others proceed downward, and the reverse. The parallel motion, as it is called, is in use between extreme parts, but then the notes must be different. Thirds or sixths move harmoniously together. When the parts are in octaves, the law against identical notes moving up or down together ceases, for the effect of such unity supersedes harmony for the moment. There are certain keys which have a close alliance to others. Given a certain key or tonic, for example, on which it is proposed to write a piece, say C: the keys having the closest alliance to this are G major, the fourth below; A minor, the third below; F major, the fourth above; and E minor, the third above. Next in order of alliance to C are E major, E flat major, A major, and A flat major. The key of B major is widely dissociated from C; so too B flat major; and F sharp major is a distant musical shore only to be approached in a long musical voyage. D minor

and D major in their relations to C can be used but transiently. D flat major can be reached readily through C minor. The passing to a new key without an intermediate chord is called a transition; when one or more chords are used, it is called a modulation. Transitions are among the brilliant effects of modern dramatic music. A great surprise, sudden and violent emotion, warrants a transition, and the change may be further enforced by an explosion of all the orchestral instruments. The transition is marked in proportion as the notes of the scale are changed. A transition from C to G for the purpose named would be timid and feeble; but one from C to A flat or D flat would be effective. In the one case all the notes of the chord of G are found in the scale of C; in the others, two notes are changed; hence the shock.—The literature of the most polite nations of Europe is rich as regards the history of music. In this Italy was first in the field, but it is probable that the Saracens, who, in translations, carried Greek literature into Spain, illuminated music as well as philosophy when they took the lead in teaching the latter. Among the laborious historians of music was Padre Martini, born at Bologna, Italy, in 1706. He ranked as the most learned contrapuntist of his time, and wrote a *Storia della musica*, prodigious for learning, though clumsy in arrangement. It occupied him 80 years, and during this time he collected 17,000 volumes and MSS., for which he was largely indebted to Farinelli, the greatest singer in Europe. When we consider however the works of Dr. Burney and Sir John Hawkins on the history of music, to England must be conceded the honor of having produced the most complete treatises up to their time. These works exhibit immense historical erudition; their critical opinions are now of greatly diminished value, and not unfrequently worthless, but they must always be admired for the earnest, persistent, and devoted labors of their authors. The Bible affords us some knowledge of the music of the ancient Hebrews, and the classics throw more or less light upon the condition of the art in Greece. It was not however until Bruce gave a drawing from a painting of a harp in a tomb at Thebes, indicating that before Athens was built the Egyptians made harps of many strings, that the learned world acquired some insight into the ancient state of music on the Nile. This revelation proves that the claim for the superiority of Egyptian music over Grecian is true; for the harp of the former is wonderful as an exhibition of mechanical skill and acoustical proprieties. Its strings vary, according to different travellers, from 18 to 21; but it is about as large as the modern harp. It is further proved from the monuments that the Egyptians had an instrument with frets like the guitar; none of the hundreds of representations of instruments of Grecian music indicate that the Greeks had arrived at that point of ingenuity. What the Egyptian composition of

music was can only be inferred, for no relics of it exist, unless the inartificial songs of the boatmen on the Nile be taken as samples of the art of a polished people. We are enabled however to arrive at the state of musical art among the ancient nations of the East, by considering it as it exists among those who still maintain their old creeds, associations, and even political forms. The Hindoo, Chinese, and Japanese music is probably what it was thousands of years ago, and merits attention. Dr. Burney says, in his "History of Music," that the oriental nations have no notation for sounds, or in other words no musical system. But this is a mistake. The Chinese even, whose music practically is unpleasant to refined ears, have some sweet-toned instruments, and a notation for the melodies played on them which is sufficiently clear. Their history and fables touching the art, moreover, antedate by many centuries those of classic nations; and divesting their legends of their fabulous dress, we find that in the time of the emperor Hoang-ti, some centuries before the Christian era, they had discovered that the octave was divisible into 12 semitones. The relations which the Egyptians assigned between the sounds of music and the planets, the signs of the zodiac and the 24 hours, are all found among the Chinese. The two Chinese instruments, the *kin* and the *che*, contain all the elements of whatever scales. Calculations among the Chinese on all combinations of sounds have been carried to a great extent. Kouie, a Chinese musician who lived 1,000 years before the assumed era of Orpheus, said: "When I play upon my *king* the animals range themselves spell-bound before me with melody." Confucius said 100 years before Plato: "Wouldst thou know if a people be well governed, if its manners be good or bad, examine the music it practises." In their system and practice the Chinese detail 8 different kinds of sound under which all can be classed: metal, stone, silk, bamboo, gourd, earthenware, skins, and wood. This division, according to them, is not factitious, but to be found in nature. They believe that, although all the different tones are to be found in each of the subtones, each however contains a note belonging to it more than to any of the others, and that nature in combining the particulars which produced it made provision for universal concord. The different substances are made into instruments. They are, beside the gong and the bamboo pipes, the *kin*, a body of thin wood curved like the top of a violin to increase resonance, with 5 strings of silk of different sizes; the *che*, an instrument kindred to the *kin*, but having the chromatic or scale of half tones; the *king*, a frame of wood with pendent stone, graduated through 16 notes, and struck with a hammer; drums; a species of flute, which anciently had but 8 finger holes; brass instruments of the trumpet species; guitars resembling the mandolin; and little boards with a pleasant sound. The Chinese make use of music in their most dig-

nified ceremonies. The sacred imperial hymn, sung with great pomp annually, is a sequence of long-drawn notes, precisely parallel to the early church music in unison, and lacking the interval of the fourth and seventh, like the old crude popular scales of some European nations. The secular melodies of the Chinese resemble dishevelled sequences of notes, such as are found in playing on the black keys of the pianoforte. They eschew all harmony on principle. Music makes no progress among the Chinese, as their sumptuary laws would restrain its development if there were genius to advance it. The head of the musicians in China is called conservator of the 5 capital virtues: humanity, justice, politeness, wisdom, and rectitude. Their music affects a certain seriousness, rejecting the sensuous element. The Persians rank vocally among them as the Italians do among us, and it has been said that singers from that country make concert tours in China. —The higher style of oriental music, which has a limited degree of melodious merit, with rhythms logically and distinctly drawn from consociation with poetry as refined and liquid as the Italian, may be found in that of India, dating also from the remotest antiquity. The poetic legends of Hindostan, and indeed of all southern Asia, rival those of China and Greece in ascribing fabulous effects to music. The Hindoos consider every art as a direct revelation from heaven; and while their inferior deities communicated other arts, it was Brahma himself who presented music to mortals. To his son Nared is imputed the invention of the *vina*, a stringed instrument with a finger or key board for frets, being of the same family as the modern guitar. The Hindoo writers on music (and there are works exhibiting earnest study of its mathematical bases) theoretically recognize divisions of the scale corresponding to our octave in 22 fractional tones, these fractions being quarters or thirds, or approximate equivalents. As to the fractions, they admit practically that they have no existence, since only tones or semitones are known in their actual compositions. The succession of tones and semitones in their scale is that of the diatonic. The 7 notes of this scale they term *swaras* or sounds, the first or key note being distinguished from all others by this generic word, and the 6 others by different names. But their words being polysyllabic, the ancient Hindoo artists took their first syllables only to designate respectively the notes of the scale. The syllables thus chosen are quite as good as the Italian *do, re, mi, fa, sol, la, si, do*, and are as follows: *sa, ri, ga, ma, pa, dha, ni*. These are the notes of the major diatonic scale. The minor mode is also familiar to East India music. The finger board of the *vina* is about two feet long, with frets like the guitar, which permit the player to divide the scale into half tones over 14 notes. The Hindoo writers have names corresponding to ours for the tonic or first, the mediant or third, and dominant or fifth of the

scale; and indeed there are multitudinous proofs of their assiduous study of the art, however limited their practical skill, owing to the paucity and imperfection of their instruments. They have music in common and triple time, that is, in groups of 2 and 3 notes severally. Ancient Hebrew music was, we may suppose, Egyptian in a less polished form.—Greek music, we have already seen, was probably little more than sonorous declamation, sustained by the lyre, and some pleasant notes from the flute and pandean pipes, with the martial trumpet on occasion. In the Greek drama the language was sung, not spoken. It was a musical recitative, and the chorus intoned. The theatres were very large, without roofs, and were capable of holding many thousands. To enable the performers to be heard well, it was necessary so to intone the voice; and moreover they wore metallic masks to add to the resonance. This was as artificial a mode of representing passion and emotion as the modern opera, though its means were fewer. The Romans were not a musical people, and their art was a copy of the Greek. During what is called the dark ages succeeding the fall of the Roman empire, the drama still existed in some simple form; and the church mysteries, or performances by religious persons of dramas, the subjects of which were taken from the Scriptures, continued to sustain it. The minstrels and troubadours, who performed and composed little lyric-dramatic pieces, show the popular taste of the chivalric ages. While music was thus infused with the passion of chivalry in secular life, and melody taking form, the foundations of harmony were laid in the services of the church. The organ, unknown to antiquity (though a "water organ" is mentioned by an old writer, probably the first attempt preceding the majestic sonorous creation of modern times), evolved what may be considered the base of the structure of elaborate compositions for instruments. Out of the fugue, itself a sublime growth of the organ, have arisen the rhetorically constructed sonata, symphony, and overture, refined by the vocal proprieties and poetical alliances of operatic music. In this procession of art all cultivated nations took part, nor do we find that England lagged behind. Cathedral and choral music especially have for 8 centuries certainly been in an advanced condition there. But the origin of passionate grace and refinement in music is due to Italy. Already her genius had produced vocal compositions of a certain merit; the most expressive of instruments, the violin and its family, unknown to the ancients, was fabricated in her cities in a manner that time has not improved upon. The modern art of singing dates from the institution of the Italian opera at Florence, and one of the pioneers of that reform was the father of Galileo. It grew out of the study of the Greek drama and the desire to revive its recitative or declamation in the Italian language. From timid beginnings have grown the bold

splendors of the present opera. The Italian language in its poetry, both as regards metre and syllabication, is the best adapted for song. Its suavity and ease in this regard are incomparable, save perhaps in the Hindoo dialects. A race of singers grew up in Italy who gave method and laws in song to the European world. The musician who had not visited Italy was not considered as having completed his studies. But the contemplative genius of northern Europe, allied to the fiery temper of the south, was necessary to produce the musical achievements of the present day.—Musical composition as it now exists may be considered under these divisions: the church, the drama, the concert room, and the drawing room. The music of the church includes the mass for the Roman Catholic service, which is the most passionate, and in the hands of many composers takes a dramatic form; and indeed, when we reflect on such intense words as the *Agnus Dei* and *Gloria in Excelsis*, no other form is left for it. Beside the mass, there are the chants, litany, and varied occasional music. The Protestant service, though lately much changed, especially in the United States, as regards its music, has rejected the dramatic style of the mass, and restricted itself chiefly to hymns and psalms of sober temper; and in the Episcopal church anthems and harmonized declamation by the choir are added. The Methodist church has taken secular airs and set religious words to them, thus following an old fashion of the Roman Catholic church. The hymns of Luther exercised a marked influence in giving simplicity and directness to Protestant church music; the involved fugue style, that is, one part chasing another in deliberate confusion through the vocal harmonies, having been much in vogue before him. In reading the old church music, one is struck with the fact that merit with the composers seemed to consist in shapeless unrhythmical passages, several moving together. The requirements of dramatic song worked a reformation in one direction, and those of congregational singing in another. Under the head of church music, oratorios may be considered. These are substantially operas of more easy composition, the composer not being obliged to regard entrances and exits, the narrow peripatetics of the footlights, and the risings of the pit in applause at the end of every act. The oratorios of each period indicate the musico-dramatic state of the art. When orchestration was poor in development, when tawdry ornamentation took the place of well defined melody, and fugues had not yet given way to the perfected and various forms of vocal and instrumental composition, we find the oratorio in the same condition as the opera. With the improvements in dramatic expression oratorios have been enhanced in value. The oratorio has been sustained in the United States by the enthusiasm of the performers, mostly amateurs, rather than by the solid support of the public.—The music of the drama,

which may now be mentioned, was during the greater part of the 18th century drawn from Italy. Handel wrote to Italian words, and in the main followed, though he improved upon, the taste of the day. (See *HANDEL*.) The great fault of his time was excessive ornamentation, so that in the hands of most composers the opera was merely a stage for exhibiting the abilities of the singers. By degrees reforms were introduced. Among the reformers was Gluck, who, after composing many years in Italy in the fashion of the day, sought to render music purely declamatory. Another musical reformer was Jomelli, born near Naples in 1714. Mozart's father, in one of his letters, speaks of Jomelli's music as being "too Gothic." It is usual to draw very wide distinctions between Italian and German music, and there is much partisanship as regards the relative value of the schools. It is true, however, that at no time have the most learned musicians been wanting in Italy—those whose music was "too Gothic," if they chose to make it so, for the rapid business and squarely melodic declamation of the stage; and that, whether we look at Italy as regards music for the church, for the opera, or that demanding great instrumental skill, we find her in the first rank. The music of the opera gradually improved, receiving great accessions from illustrious composers of different nations. Among the immediate successors of Mozart, Spontini holds an illustrious place. In his *La Vestale* there are inspirations which would pass for Rossini's, so identical are the effects. Cherubini may be cited as the composer who particularly linked the styles of the close of the last century with those of this. This most eminent writer produced operas which held the possession of the stage, and was equally successful in his sublime church music. He competed with Reicha moreover in his profound treatises on the fugue. Supremacy cannot be accorded to any composer beyond another in that or any other musical walk. In brilliant fluency Rossini excels all others who have written for the Italian opera; but then it must be remembered that he was preceded by Mozart, whose operas were written to Italian words and with melodies identical in shape, in caesural pauses, in syllabication, and in relation to the chords, with the Italian school of Paesello, Piccini, and Cimarosa, and who must be considered an Italian composer as regards the opera. The most perfect operas are those of the 19th century, partly because the increased skill of the orchestral players enables the composer to delineate character in his instrumental painting. Execution on all instruments has immensely improved in this century, as well as the excellence of the manufacture of wind instruments; and these artistic and mechanical superiorities impart a splendor to the orchestra to which it was before a stranger. The theory and practice of vigorous accentuation and climax have been perfected; and the singer accordingly who wishes to sway his auditory, chooses an opera of

this century and not one of the last. Whatever tendency there may have been to avoid excessive ornamentation in singing, and maintain the theory of Gluck, was set aside for many years by the genius of Rossini. Mozart, who indulged occasionally in ultra-florid music, or several notes rapidly sung to a syllable, was not brilliant in that department; Rossini was, and his ornate arabesque work not being of the old pattern, that is to say, merely roudades, following a plain melody, or even without any such distinct melody, but being integrated with the melody itself, he struck the secret of popularity, and swayed Europe musically. His sense of rhythm being ever present, and his persistence in the *ictus* of the measure exceeding all his predecessors, he allured and excited his auditors to a degree before unknown. The voices, whether base, tenor, contralto, or soprano, were made to do this ornate work, which was lavished on serious and comic scenes alike; and yet with all this profusion of notes there are ever present touches of severe simplicity, which was completely exemplified when he wrote for the French stage and presented *Guillaume Tell*. His *Mosé in Egitto* also abounds in sublime passages of absolute simplicity. In the church music produced by Rossini there are the same contradictions; his *Stabat Mater*, though broad and lovely, is defective in the austere, heart-broken expression proper to the grand desolations of the theme. While Rossini was electrifying Europe, there arose a consummate genius in Germany, Carl Maria von Weber. Grasping all the extensions of orchestration in execution and effect, this composer wrote overtures of larger texture and clearer dramatic personification than any predecessor, and infused into his operas qualities which placed him at the head of a new school, the romantic. His vocal writing often wants fluency, though this is less apparent in *Der Freischütz* than in his *Euryanthe*; had his metres been better, his music would not have been amenable to this charge. But the transcendentalism of his music was the most daring ever attempted. In a certain class of passionate expression he was without a rival; certainly no such intense womanly portraiture of love was drawn in music before his *Agatha*. More than this, new problems of harmony can be found in his weird scene of the wolf's glen, which has a direct affinity and equal rank, so far as dramatic music and poetry may be compared, with Shakespeare's witches in "Macbeth." The ordinary laws of harmony are here freely set aside by Weber to produce supernatural effects; and the terrible result is coördinate with the philosophy of the design. Many of the operas produced by eminent composers for the French stage, among whom Meyerbeer stands preëminent, combine grace, brilliancy, breadth, and grandeur. "The Huguenots," by Meyerbeer, may be cited as the grandest subject for a musical drama of any on the stage. "William Tell" is wonderful for its breadth, and the dazzling variety of its characteristic national music. A

single point in the trio, the chords under the phrase *mon père*, was an invention largely affecting subsequent dramatic expressions. The benediction of the poniards in "The Huguenots" is copied from this Rossinian flash. In *Masaniello* Auber imparted a popularity to characteristic Neapolitan music which carried it round the world, and made the barcarole a household musical word. The romantic, tender, and impassioned strains of Bellini gave a new impulse to the Italian music, and established a greater popularity for it both through Italian words and English translations than it had hitherto enjoyed. The directness of his melodies, his use of a few notes instead of many for masculine voices, enabled amateurs to seize hold of them, who were unable to cope with the floridities of Rossini. In this new school Donizetti was a peer of Bellini, and the author of the strains of *Edgar* has never been surpassed in popularity. The latest accession to Italian music is Verdi, combining clear, strong, well defined melodies, with a perfect apprehension of climax, intuitive dramatic perception, and knowledge of stage business, but with certain errors, such as overstraining the voice for effect, and soon ruining it.—It is worthy of remark that no earlier secular piece of music in parts for voices can be found than one with English words: "Sumer is i-cumen in." This would prove that the northern islanders had made as much progress in harmony as their southern neighbors centuries ago. That music was much cultivated in England in the time of Queen Elizabeth there is ample evidence, and gentlemen then were commonly able to perform on the instruments in fashion. The gradual change from Catholicism to Puritanism, and the destruction of the theatre, owing to the spread of more sombre tastes, appear to have caused music to fall in public estimation for a period; and the exceedingly coarse and ignorant manner in which Handel, Buononcini, and the compositions of their day were spoken of by wits and poets, would argue a national decline in a love for the art. Shakespeare, on the contrary, glorifies music in many passionate passages. Indeed, the dramatist's accurate knowledge of music makes him introduce into "King Lear" a technical phrase which sorely puzzled the academic commentators. The music of the old English composer Purcell, though frequently crude, is marked by a vigor and a correct art of word-setting that formed the basis of Handel's oratorios. Purcell had probably no contemporary superior. The music of "Macbeth" by Locke, though homely, is genuine in its way, and does honor to his memory. Dr. Arne, in the 18th century, made a brilliant though practically unsuccessful effort to rival the Italian opera, by the introduction of recitative song after the Italian fashion. One of the special glories of the English school of music is glee writing. In this a long list of worthies appears, among the later of whom Sir Henry Bishop was particularly distinguished.

The genius of Handel confirmed the practice of writing in the fugue style in music to English words. By degrees, however, this was followed by other and more dramatic forms. In fugues the base has as much motion as the treble, giving as it does the leading melody equally with it; and this constant sub-movement is evident in the other pieces of vocal music where the fugue dominated. By degrees the base adopted more of the repose due the foundation of music, leaving the melody to float gracefully and passionately above it; and as a sequence the base itself took occasionally a cantabile form as exhibited in solos for the voice and instrument. Beethoven did much for this style in his instrumental music, the increasing taste and ability of violoncello and double base players permitting it. A single instrumental performer who excels his predecessors is sufficient to change or improve the style of composing for his instrument. The British composers, amid much public neglect, the fashion being set for foreign music, have steadily advanced with the steps of the art, and excel now in every department. The names of Macfarren, Wallace, Balfe, Rooke, and others, are eminent among music-lovers. The great drawback to English vocal dramatic writing has been defective versification, wanting alike in softness, continuity or fluency, and variety. The same monotony has marked other than lyrical poetry; lately, however, there are changes for the better in this department. Among the special beauties of British music must be named the ballad. The Scotch, Irish, Welsh, and English ballad airs are all different in character. They have had the advantage of new words written to them by the best poets. Some of them steadily resist changes in fashion, and are as popular now as ever. Eminent composers, Haydn, Beethoven, and others, have harmonized these national lyrics and set accompaniments to them. The choicest Irish airs were collected by Thomas Moore and allied to his beautiful inspirations, Sir John Stevenson making the musical arrangements. All the other European nations have their national songs, differing in characteristics; and these underlie the varying qualities of the composers to a greater or less degree. The most esteemed writer of the music of songs, of a character which pleases refined ears, is Schubert, whose genius is remarkable. It was displayed also in orchestral and quartet music. Robert Schumann is among the eminent names of the composers of German songs, and his genius also took the wider field of symphonies and piano music; in all these he essayed original walks. Among the German operatic composers of the present time whose works excite attention is Wagner. He also holds a fluent pen in expounding his theories. He lays much stress on orchestration, in which he excels, as he also does in the logical adaptation of words to music. The most popularly effective piece in his opera of *Tannhäuser* is a march with chorus, in which the melody is well defined. The ab-

sence of clearly cut, square melodies in the vocal part generally of this opera is not compensated for by any new theory, however earnestly enforced. It may be assumed that the composer who can produce the most effect with the simplest means will do so; and melody is as important now as when Haydn so insisted on it. The "progressive school" has succeeded very often in making what ought to be beautiful, grim and ghastly. Among the French composers the name of M. Halévy stands eminent, his opera *La Juive*, produced 80 years ago, having maintained its place with undiminished effect, though after this he was less successful. M. Herold won a place in the first rank of French composers by his opera of *Zampa*. M. Hector Berlioz has devoted an enthusiastic life especially to instrumental music, and in the romantic school has evolved new effects. He is also the author of an elaborate work on the art of instrumentation. M. David made a great success in his ode-symphony *Le Desert*, in which recited strophes and vocal and instrumental music, with an oriental coloring, produce a most pleasing effect. The German composer Spohr, lately deceased, through a long life exhibited his genius in every possible form. His *Faust* has much that is kindred in temper with *Der Freischütz*. His *Jessonda*, in another style, is equally artistic. To the eye these works are disfigured with the pedantry of remote modulations clouded with "accidents"—a show of learning which does not add to their effect. Spohr's oratorios do not appear to hold their place in England since those of Mendelssohn were written. While there has been much learned discussion in Germany as to what music ought to be, the public of Vienna equally with that of New York has been pleased with the strains of Flotow, whose style is most akin to the comic operas of Auber. In the opera of *Martha* especially there is a lightness, grace, and piquancy which will compare favorably with the French comic school. Oosta, the celebrated orchestral leader, lately achieved a great success in the production of an oratorio called *Eli*, an elegant and imposing work. Composition for the orchestra received its greatest development at the hands of Haydn. This illustrious composer when a boy had the benefit of instruction from Porpora, the great Italian composer, from whom he derived his musical vocal knowledge; and he learned the art of setting words to music from Metastasio the poet. But with all these advantages he failed as an operatic composer, while he succeeded in orchestral music and oratorios. His genius for melody was so great that, although he closely followed Handel as to time, his melodies are a century in advance of that eminent composer in point of grace and symmetry and essential beauty. His muse was kindred with Mozart's, and years have only added to his fame. In symphonic writing in many respects he has not been excelled. In breadth and depth, however, the palm for that department has been awarded to

his successor Beethoven.—The form of the symphony is derived from that of the piano sonata or violin quartet; as a general thing, it is composed of 4 movements: an allegro, usually the principal movement; then a slow movement; then a minuet, or old dance tune; then a rondo, or finale, of quick movement. There is no organic completeness in this design, so far as the number of movements is considered. They are all distinct, and there might as well be one movement, or 40 if so many could be compassed. But symphonies and quartets were composed according to this method as though according to an irrefragable law. Their structure is: a theme or melody in a given key, say C major; a passage leading to another key, G major, the most closely related to the first, with a strong assertion of the chord of the seventh or the fifth of G, which is D, before the second theme or melody is taken; then follows some accessory and climacteric matter, and we arrive at the end of the exposition of the primary ideas. The second part is taken up, generally after the first is repeated, but without stopping; and now commences what is called the development of ideas, in which the primary ones are set off in various ways, by new harmonies, or accessories of melody, by double counterpoints (that is to say, placing phrases indifferently as the base or treble), by modulations, by instrumentation, and so forth; and this runs into a repetition of the original melody, to which the second melody is added, but this time in the same key with the original; and the whole is crowned with a musical peroration in which appear the most ambitious flights and climaxes. The development of ideas is peculiar to instrumental music, for on the stage the business is too rapid to admit of it except slightly. This privilege to write untrammelled, and the absence of verbal and vocal restraints, make symphonic writing easy in comparison with that of the opera. The second movement of the symphony is a clear melody, with accessory and developed matter, and the melody repeated with a short peroration. The third is the minuet, measured and somewhat developed. In Beethoven's symphonies the minuet is set aside for the *scherzo*, or playful movement, in which piquancy is aimed at. The last movement of the symphony is a melody or theme with accessories, its repetition, and a peroration. Sometimes the last movement is the most important. In the choral symphony of Beethoven the voices are added. (See BEETHOVEN.) Quartets and sonatas are on the same plan as symphonies, but generally briefer, as the variety of instrumental coloring in an orchestra warrants greater length.—Chamber music, or that for the drawing room, received a great impulse from the sonatas of Corelli, an Italian composer who wrote in the early part of the 18th century. Carl Emanuel Bach wrote sonatas the worth of which cannot be overpraised. Many eminent composers—Clementi, Dussek, Steibelt, Hummel, Von Weber—followed Haydn and Mozart in sonata

writing; and the large hand of Beethoven was also most distinctly felt there. With all this genius there was something wanting in music for the pianoforte. About 1840 this want was supplied, when Thalberg arose and began his piano illustrations of dramatic music, in which he gave the precise vocal pitch of the airs on the piano, and overarched them with a dazzling spray of sound that infused new life into the instrument. Liszt also added his *tours de force*; and mention should be made of Herz, whose brilliancy was only eclipsed by that of Thalberg. The germ of Thalberg can be found in the extraordinary violin playing of Paganini—that is, the air vocally treated, and set off with arpeggios. The later composer for the piano who has made the most distinct impression by his genius was Chopin; he was redolent of ideas, and master of the mode of setting them off to advantage. As a poet for the instrument he held a first rank; and his music has all the brilliancy which characterizes the modern dramatic school. The compositions of Mendelssohn for the piano are among the best legacies of his genius. In other instrumental music the skill of the present day has reached such a height as to induce the belief that it has culminated. The principal performers in Jullien's orchestra as exhibited in the United States several years since—König on the cornet, Bottesini on the double bass, and Lavigne on the hautboy—left nothing of excellence to be desired.—The past and present condition of music in the United States merits a special word. At the close of the 18th century, during the administration of Washington, the institution of a theatre at the seat of government, which was then at Philadelphia, drew together some English actors, of whom tradition speaks favorably as singers of their national music. Among the rest, Incledon, the great English tenor, enlarged the popular ideas as to song. Afterward, in New Orleans M. Davis established an opera company of much merit, and an orchestra to match. The appearance of an Italian opera troupe in New York about 1825 worked a revolution. This troupe was brought here in part through the instrumentality of Signor Da Ponte, the friend of Mozart and the writer of the libretto of *Don Giovanni*, who lived for some time in New York. The director of the troupe, Signor Garcia, was a great artist, and had all the traditions of the old Italian school. His daughter, Madame Malibran, showed immense talent, and her fame subsequently filled Europe. A few years afterward another Italian company, composed of admirable artists, further influenced the musical taste of the public. Mr. and Mrs. Wood next came, but it was not until the latter appeared in a translation of *La sonnambula* that public enthusiasm glowed at her performances. She subsequently appeared in *Norma* translated, and performed in Philadelphia with surpassing splendor; for although the theatre was small, the orchestra numbered 50, the chorus 70, and the stage decorations

were even superior to those of the *Italiani* at Paris. Mr. and Mrs. Seguin, Mr. Frazer, Miss Shirreff, Mrs. Austin, Miss Pyne, Mr. Guilmette, and others contributed greatly to spread a taste for opera through the English language. An attempt was made to build a grand opera house in Philadelphia, but failed at the period of the financial calamities about the year 1840. Since then an opera house has been built there which is considered a model of completeness. Boston had the honor of erecting the first very large opera house, a splendid structure and worthy of the intellectual culture of that city. The opera house of New York is perhaps the handsomest in the world, though it is bad as to interior shape. Cincinnati has also built a fine opera house, said to rival any for its decorations. A new one has lately been erected in New Orleans, and Brooklyn has one in process of construction. The building of these houses was preceded by the visits of the best European artists, and now the American public have nothing to hear superior to what they have heard. In orchestras, especially in New York, there have been immense improvements. The philharmonic society of New York numbers nearly 100 experienced performers. In military music New York holds a first rank. In the manufacture of musical instruments the United States rival Europe. At the exhibition of the New York crystal palace it was found that the American makers were as good as the European. Pianofortes of the best quality are now produced, and the annual sale is estimated at from \$12,000,000 to \$15,000,000. The manufacture of church organs is carried on to an enormous extent. In the printing or engraving of music a great traffic is maintained, but chiefly in sheet music, or short pieces. Several young ladies of American birth have appeared on the Italian stage, and some of promise are now studying in Europe. One of them, Miss Adelaide Phillips, a contralto, has achieved eminence as a dramatic artist. Mr. Gottschalk, an American, has acquired a European reputation as a pianist. In composition, Mr. Bristow has written symphonies with eminent success, as well as vocal music. His latest work, a *Te Deum*, is a carefully executed classic. Mr. Robert Stoepel has composed a vocal and instrumental work, on Longfellow's "Hiawatha," full of appropriate portrayings and most minutely elaborated. In musical literature there are several flourishing periodicals.

MUSK, a concretionary substance of peculiar and most powerful odor, which is secreted in a projecting hairy sac or bag between the umbilicus and the prepuce of the male of a small Asiatic animal, shaped like a deer, and named by Linnaeus *moschus moschiferus*. The sac is from 2 to 3 inches long, and contains from 2 to 3 drachms of musk, which when first removed is soft and almost liquid, but afterward hardens and dries into a substance resembling dark-colored snuff, coarsely granulated. The musk deer, as the animal is commonly called, is found

in the central mountainous regions of Asia that lie between India and Siberia, frequenting the colder portions of these countries near the line of perpetual snow. It is a timid animal, coming out for food chiefly at night, and is remarkable for its agility in leaping among the rocks. The hunters, who pursue it for the sake of its skin as well as for its musk, immediately cut off, tie up, and dry the sac, or, as it is called in commerce, the pod; and in this state the article is transported. In China, where it is chiefly supplied to commerce, the pods are packed for shipment in catty boxes holding from 20 to 25 each. A single pod being worth from \$15 to \$18, the adulteration of the article is a profitable operation; and the Chinese practise it with great skill, and to such an extent that genuine musk is scarcely known in trade. Dried blood, having the appearance of musk, is introduced into artificial sacs made of the skin of the animal, and a variety of other substances are added, with which enough musk is intermixed to give its strong odor to the mass. Musk of different qualities is also mixed together by the Chinese with the intention of passing off the whole as the best. That of Tonquin, which is obtained only from China, is far stronger than that of southern Siberia, which is also carried to China as well as to Russia. The Siberian article is received to some extent through Europe. The pods are larger and more elongated than the Chinese, and the musk is in finer grains, and possesses a fetid odor; while the Chinese is very strongly scented, and has an odor somewhat ammoniacal. A variety exported from Calcutta, where it is brought from Thibet and the Himalaya mountains, is esteemed better than the Siberian, but inferior to the Chinese.—Musk is familiarly known as a perfume of most penetrating and lasting odor. According to the accounts of Tavernier, Chardin, and other travellers in Asia, it is so powerful when first taken from the animal that those exposed to its influence are in danger of hæmorrhage from the nostrils, even when the nose and mouth are protected by coverings of linen. Headache is often produced by approaching the sacs even in the open air. The substance was formerly in high repute as a medicine, and is still largely used by eastern nations and to some extent in civilized countries, being administered in the form of a pill or emulsion. Its use is as a stimulant and antispasmodic, and its effects have been found highly beneficial, among other instances, in dangerous cases of infantile convulsions caused by spasm of the intestines. Musk is however chiefly of value as a perfume; and it is the most remarkable of substances for the diffusiveness and permanence of its odor. A whole room has been known to be perfumed with it for 30 years, and no perceptible loss of weight in the musk was occasioned thereby; and specimens known to be 100 years old were as strong as the fresh article. One part communicates its smell to more than 8,000 parts of inodorous

powder. Its taste is disagreeably bitter and acrid. Its chemical composition is variable and exceedingly complicated. A volatile compound, probably of ammonia and a volatile oil, has been found by Guibert and Blondeau in the proportion of 47 per cent. Beside this, they separated a large number of other ingredients.

MUSK DEER (*moschida*), a family of small ruminants, living in flocks on the continent of Asia and the larger islands of the Indian archipelago. They have no horns in either sex and no lachrymal sinuses, but the males have two elongated canines in the upper jaw, used as instruments of defence and offence; the legs in some are exceedingly slender; the name is derived from the presence in the males of some of the species of a bag or pouch beneath the abdomen, which secretes the powerfully odoriferous substance known as musk. The true musk deer (*moschus moschiferus*, Linn.) is of about the size of a small roebuck, with shorter legs and thicker body; the color is reddish brown, paler below and on the inside of the limbs, with throat and streak on each side of the neck white, and sometimes whitish gray on the sides; the hair is stiff, long, and curled; the canines project an inch beyond the closed mouth; the hoofs are long and sharp, well adapted for the rocky places in which they delight to dwell in the manner of the chamois; the ears are long and the tail short. It is shy, very active, and not easily taken; it is pursued chiefly for the odorous secretion, which is strongest and most abundant during the rutting season. This species is distributed over the mountainous regions of central Asia, especially Thibet and China, extending even into northern Tartary. The flesh is sometimes eaten, and the skins are prepared as articles of clothing and as leather. A species is said to exist near Sierra Leone, on the west coast of Africa.—In tropical Asia and its islands are the allied genera *tragulus* (Briss.) and *meminna* (Gray), containing the most diminutive of ruminants, some of them no larger in the body than a hare. The napu musk deer (*T. javanicus*, Briss.) has shorter ears, smooth hair, very slender legs, with the supplementary hoofs at a greater distance from the ground; like the rest of the genus it has no musk sac; it is about the size of a full-grown hare, of a glossy ferruginous brown color, lighter along the back; throat, chin, under parts, and inside of the limbs white; on the fore part of the chest are 8 broad, white, radiating stripes, separated anteriorly by bands of blackish brown; and a white line passes back on the cheek from the lower lip. It is commonly called the mouse deer in the straits of Malacca. It inhabits Java and Sumatra, frequenting thickets near the sea shore, and feeding principally on berries of a species of *ardisia*; it is easily tamed, when taken young. The kanchil (*T. pygmaeus*, Briss.) is of the size of a small rabbit, of a delicate and elegant shape, and very active; this is the species which, when pursued, is said to leap to the branches

of a tree, hanging suspended by the canines until its enemy has passed by; the flesh is excellent. The color is reddish brown on the back, bay on the sides, white below, with 3 white streaks under the throat; it is common in the peninsula of Malacca and the neighboring islands, where it is captured in traps or by throwing sticks at the legs when it comes to feed on the sweet potatoes at night; it is very cunning, feigning death when caught in a noose.—The Ceylon musk (*meminna Indica*, Gray) is about 17 inches high, an elegant, graceful, and gentle animal, whose flesh is excellent food; the ground color is cinereous olive, spotted, striped, and barred with white; it lives in the jungles of Ceylon and of India.

MUSK OX (*ovibos moschatus*, Blainv.), a ruminating animal found in the arctic regions of America, seeming to form, as its generic name imports, the connecting link between the ox and the sheep. It is about the size of a 2-year-old cow, 5½ feet from the nose to root of tail, and weighs about 700 lbs., 2 or 3 times as much as the reindeer; the head is large, and surmounted by broad flat horns in both sexes; in the males the horns meet on the median line of the head, from which they bend down on the cheeks, and then turn outward and upward, much as in the gnu; dull white and rough on the basal half, they are smooth and shining beyond, and black at the point; the horns of an old male measured by Dr. Kane were 2½ feet from tip to tip, and each 1½ feet to the median line of the head. The nose is very obtuse, with only the small space between the nostrils naked; the ears not perceptible, the tail concealed by the hair, the legs short, and the hoofs broad and inflexed at the tips. The hair is so long that it almost reaches the ground, so that the animal looks more like a large sheep or goat than an ox; the color is brownish black, more or less grizzled. The musk ox frequents arctic America from lat. 60° to 79° N., and from long. 67° 30' W. to the Pacific coast; though Dr. Kane saw no living specimens, the skeletons and probable footmarks were so numerous that he was inclined to believe the statement of the Esquimaux that these animals had been recent visitors, and probably migrated from America to Greenland; they are generally seen in herds of 20 or 30, in rocky barren lands, and feed on grass and lichens; the rutting season is about the end of August, and the young are born toward the first of June. Though the legs are short, they run very fast, and climb hills and rocks with great facility; they are difficult to approach except by the concealed hunter; the males are irascible, and often dangerous when slightly wounded; the flesh, when fat, is well tasted, but when lean smells strongly of musk, as does the whole animal, whence its name; the hair is long and fine, and, if it could be obtained in sufficient quantity, would be useful in the arts; the skin is made into articles of dress by the Esquimaux. The tracks made by this animal in the snow are much like those of the rein-

deer, somewhat larger, and can be distinguished only by the skilful hunter. Only one living species is known, and the geographical distribution of this is not precisely ascertained. It is very rare in collections, the only specimen in the United States being in the museum of the Philadelphia academy of natural sciences, a stuffed skin presented by Dr. Kane. It is said to occur fossil at Eschscholtz bay on the N. W. coast. The *bos Pallasii* (De Kay) of North America and the fossil oxen found in various parts of the United States, coming near the musk ox, have been described by Dr. Leidy, under the name of *bootherium*, in vol. v. of the "Smithsonian Contributions, to Knowledge" (1853), as the *B. cavifrons* and *B. bombifrons*; these probably, he says, were clothed in a long fleece, and inhabited the great valley of the Mississippi just anterior to the drift period. The Siberian and northern European fossils probably belong to the genus *ovibos*.

MUSKINGUM, a S. E. co. of Ohio, intersected by the Muskingum river and drained by Licking river and other branches; area, 665 sq. m.; pop. in 1860, 43,373. It has a diversified surface and fertile soil, and contains bituminous coal, iron ore, and salt, the last procured by deep boring into the whitish sandstone, or salt rock. The productions in 1850 were 415,847 bushels of wheat, 1,144,855 of Indian corn, 281,748 of oats, and 194,866 lbs. of wool. There were 6 establishments manufacturing 189,000 bushels of salt annually, 20 flour mills, 19 saw mills, 4 iron foundries, 1 cotton and 8 woollen factories, 14 tanneries, 5 printing offices issuing 1 daily, 1 tri-weekly, and 6 weekly newspapers, 105 churches, 1 college, and 15,800 pupils attending public schools. It is intersected by the Ohio canal and the central Ohio railroad; and the Cincinnati, Wilmington, and Zanesville railroad has its terminus at the capital, Zanesville.

MUSKINGUM, a river of Ohio, formed by the junction of the Walhonding and Tuscarawas, which rise in the N. part of the state and unite at Coshocton, whence it flows in a S. E. direction for about 110 m. through Muskingum, Morgan, and Washington counties, and enters the Ohio river at Marietta, its mouth being 225 yards wide. At Zanesville it is obstructed by falls. Here there is a canal with a dam and locks. It is navigable for steamboats to Dresden, 95 m. from its mouth, at which place there is a side cut to the Ohio canal.

MUSKOGEEES. See **CRKKEA**.

MUSKRAT (*fiber sibiricus*, Cuv.), an American rodent, the only species of its genus, well known for its aquatic habits; it is also called musquash, musk beaver, and ondatra. The dentition is: incisors ½, and molars ¾-¾, in all 16 teeth. The body is rat-like, the head and neck short; the eyes and ears very small, the latter having no special arrangement except their dense fur to exclude the water; the upper lip not cleft, and hairy between the teeth and nose; lips thick and fleshy; nose thick and ob-

tuse; 6 horizontal rows of whiskers, with some over the eye and under the chin; the legs short, and the thighs hid in the body; the claws compressed and incurved, the 8d toe the longest on the fore feet and the 4th on the hind feet; the hind feet appear slightly twisted, the inner edge posterior to the outer, by which the animal can "feather the oar" when the foot is brought forward in swimming; all the feet are partly webbed, naked below, covered with short hairs above, and have their edges more or less margined with bristly fringes; the tail is $\frac{3}{4}$ as long as the body, compressed, 2-edged at the end, scaly, with short thin hair; the fore feet are 4-toed, with a wart-like thumb, and the hind feet 5-toed. The head and body are from 18 to 15 inches long, and the tail 9 or 10 inches; the general color is ruddy brown above, darker on the back, and cinereous beneath; some specimens are very dark brown; the long hair is fine, compact, and silky, with coarser hairs intermingled, especially above. The dentition is arvicoline, but the characters of the feet and tail, the larger size, and the great expansion of the temporal bones over the head, are sufficient to distinguish it. It is more extensively distributed over North America than the beaver, but, unlike the latter, does not disappear at the approach of civilization; it is found from the Atlantic to the Pacific, and from the Rio Grande to arctic America, even on the N. W. coast; it is strictly an American animal, the skins obtained from Kamtschatka having been procured from the tribes on the American side of Behring's straits; fortunately for the rice planter, it is not found in the alluvial lands of Carolina, Georgia, Alabama, and Florida, though it extends much further south. Its favorite locality is a grassy marsh or bank of a lake or sluggish stream; nocturnal in habit, it is occasionally seen in the daytime swimming a stream or diving into the mouth of its hole; awkward on land, it is an excellent swimmer and diver, and very lively and playful in the water; it often swims 15 or 20 yards under water. The burrows are made in banks skirting streams, the entrances being under water, thence leading upward above the highest freshets; their winter galleries often extend 40 or 50 feet from the water, the central part containing the nests made of dried reeds and grasses; in swamps and marshy lands they sometimes raise mounds of sticks, twigs, and leaves from 2 to 4 feet above the surface, in which are their grassy beds large enough to accommodate several animals; the entrance to these is also under water, the surface of which they take care shall not be entirely frozen. The fur was once in great demand for hats, and hundreds of thousands of skins were annually exported for this purpose to Europe; their value is now only 10 to 25 cents each, as they are used chiefly for cheap furs; the animal, however, is generally killed when possible, to prevent the destruction of dams and embankments. They are not at all cunning, and may be caught in ordinary box

traps, or in steel traps placed just under water and baited with sweet apples or parsnips; they are often dug out of their holes, hunted by dogs, and speared in their nests. Like the common rat, they are omnivorous, feeding on grasses, roots, vegetables, mussels and other mollusks, fruits, and even flesh; they are injurious rather from digging under embankments and undermining meadows than from destroying vegetation either in field or garden; great numbers are killed by lynxes, foxes, owls, and other rapacious mammals and birds. They are very prolific, bringing forth 4 to 6 young at a time, 8 times a year; they have a strong musky odor, which to most persons is less offensive than that of the mink, and far less so than that of the skunk; the flesh is considered palatable in some localities, though it is generally very fat.

MUSLIN, a thin kind of cotton cloth with a downy nap on the surface. The name is derived from the town of Mosul in Asia, where it is said to have been originally manufactured. The first importation of the article into England from India was in 1670, and in 1690 it was manufactured both in England and France. The muslins produced now by machinery in Great Britain, France, Germany, and Switzerland, rival in fineness of texture and beauty of finish those woven in the hand looms of the East.

MUSONIUS, CAIUS RUFUS, a Roman stoic philosopher, who lived in the 1st century A. D. Nero banished him to Gyarus in 66, under pretence of his having been a party to the conspiracy of Piso. On the death of Nero he returned from exile, and when Antonius Primus, the general of Vespasian, was advancing against Rome, he joined the embassy sent by Vitellius to make terms with his enemies. After the downfall of Vitellius he became reconciled to Vespasian, who suffered him to remain in Rome. The only edition of the extant fragments of his works is that of Peerlkamp (Haarlem, 1822).

MUSPRATT, JAMES SHEERDAN, a British chemist, born in Dublin, March 8, 1821. He removed at an early age to Liverpool, where his father established a large chemical manufactory, and while at school showed a predilection for the study of chemistry. At the age of 18 he travelled through France and Germany, and subsequently studied in the laboratory of Professor Graham of Glasgow, whom he accompanied to London. Before reaching the age of 17 he was sufficiently advanced to be intrusted with the chemical department in a large manufacturing establishment in Manchester, and he also published a lecture on chloride of lime. After an attempt to embark in business in America, by which he lost money, he repaired in 1848 to Giessen and became a pupil of Liebig, under whom for the next two years he applied himself indefatigably to the study of the higher branches of chemistry. His first original paper of importance was one on the sulphites, published in Liebig and Wöhler's *Annalen*, in which he proved the analogy between the sul-

phites and the carbonates, "a discovery," according to Berzelius, "overlooked by all previous investigators," and which procured him the degree of doctor of philosophy. In conjunction with Dr. Hofmann he subsequently discovered the important organic bases, toluidine and nitraniline. While at Giessen he edited Plattner's "Treatise on the Blowpipe," with many valuable additions. Between 1845 and 1847 he travelled over Europe, returning in the latter year to Giessen, where he discovered several remarkable bodies produced from the sulpho-cyanides of ethyle and methyle. In 1848 he returned to England, was married to Miss Susan Cushman, an American actress, and soon after founded a college of chemistry in Liverpool, of which he was appointed the director. In 1854, at the request of a publishing house in Glasgow, he commenced a dictionary of chemistry, published in Europe and America in parts, reaching a circulation of upward of 60,000 copies; it was completed in 1860 (2 vols. royal 8vo.). It was translated into German and French, and the number of subscribers in those countries exceeded 20,000. His remaining works are: "Outlines of Qualitative Analysis for Students;" papers on the selenites; on carmufellic acid, a new acid from cloves; on the influences of chemistry on the animal, vegetable, and mineral kingdom, &c.

MUSQUASH. See MUSKRAT.

MUSSCHENBROEK, PIETER VAN, a Dutch mathematician and natural philosopher, born in Leyden, March 14, 1692, died there, Sept. 19, 1761. He was educated at the university of Leyden, and in 1717 formed an intimacy with 'sGravesande, with whom he pursued a common course of study, and who subsequently cooperated with him in introducing the Newtonian system of philosophy into Holland. In 1718 he took his degree of doctor of medicine, and soon after visited England for the purpose of seeing Newton and making himself acquainted with his system. In 1719 he was appointed professor of philosophy and mathematics and professor extraordinary of medicine in the university of Doesburg, which he resigned in 1723 for the chair of philosophy and mathematics at Utrecht. Here he remained until 1739, refusing in the mean time a professorship at Göttingen, and about 1740 accepted the chair of mathematics at Leyden, which he filled during the remainder of his life. His works contain many original researches in experimental physics, and are among the earliest expositions of the Newtonian philosophy; the cohesion of bodies, the phosphorescent properties which many bodies acquire from exposure to light, magnetism, capillary attraction, and the size of the earth being among the subjects most successfully treated.

MUSSEL, a well known lamellibranchiate bivalve mollusk of the genus *mytilus* (Linn.). It belongs to the dimyarian group, or those having two adductor muscles, the anterior being small; the mantle has a distinct anal orifice;

the foot is small, cylindrical, grooved, with many retractile muscles and a large silky byssus divided to its base; the shell is longitudinal and subtriangular, with the beaks terminal and pointed, dark-colored and shining. The common salt water mussel (*M. edulis*, Linn.) is from 1 to 2½ inches long and 1 inch broad, of a greenish black color externally and purplish and bluish white within. This species is esteemed as food in Europe; they lie together in large beds uncovered at low water, and are more widely spread and more easily obtained than the oyster; they are most esteemed in autumn, as in the spring or spawning season they are apt to disarrange delicate stomachs and to produce a cutaneous eruption; thousands of bushels are annually obtained for food and bait for deep sea fisheries, affording employment for hundreds of women and children, especially along the frith of Forth; they anchor themselves very firmly to rocks and stones by the horny threads of the byssus, directed by means of the foot, and attached by their broad disk-shaped extremities. The common mussel of New England (*M. borealis*, Lam.), by some considered the same as the last species, is eaten, fresh and pickled, in some parts of the country, but is more commonly used for bait or manure. The forms of these shells are very various, from accidental distortions or from the shape of the cavities and crevices in which they are commonly wedged. Several other species are described.—Another shell, commonly called mussel by the fishermen, is the allied genus *modiola* (Lam.), known in Europe as the horse mussel. Our common species (*M. modiolus*, Turton) is from 4½ to 6 inches long and from 2½ to 3 inches wide; the shell is thick, coarse, and rough, with the beaks subterminal; the color externally is chestnut or dark brown-pearly within. It inhabits deep water, attaching itself very firmly to rocks, from which it is torn in great numbers during violent storms; it is almost always more or less distorted, and has sea weed or some parasite attached to it; though too tough for food, it makes excellent bait for cod and other deep sea fishes, but is very difficult to obtain when wanted. Other species live in brackish water; some in Europe are said to burrow and make a nest of sand and fragments of shells.—The fresh water mussel (*anodon*) and river mussel (*unio*) are dimyarian, with a large foot not byssiferous in the adult; the hinge is toothed. The *A. fluviatilis* (Gould) has a thin, inequilateral shell, grassy green externally and lilac-tinted white within, and attains a length of 4½ inches; it is common in mill ponds and sluggish streams. Many other species of this genus, and of *unio* and allied genera in North America, have been specially described by Mr. Isaac Lea. Some of the *unio*, both in Europe and in this country, produce very fine pearls, and a short time since there was a general pearl hunting in many parts of the United States, which resulted in the finding of a few valuable specimens after an immense

amount of generally unprofitable labor. The pearl mussel of Europe (*U. margaritifera*, Linn.) has long been famous for the ornamental excrescences found in its shell, some of which have been of rare beauty, large size, and great value—"not orient pearls, but pale and wan."

MUSSET, LOUIS CHARLES ALFRED DE, a French poet, born in Paris, Nov. 11, 1810, died there, May 1, 1857. His father was M. Musset-Pathey, a government employee, known by his *Histoire de la vie et les ouvrages de J. J. Rousseau* (28 vols. 8vo., Paris, 1822-'6). Alfred Musset attended the collège Henri IV., where the duke of Orleans, son of Louis Philippe, was among his classmates. He is said to have written a tragedy as early as 1826, and in 1828 received a prize for a Latin dissertation on the "Motives of Human Judgment." He alternated for some time between the studies of medicine, law, and art, and was for a short period attached to a banking house, but was eventually encouraged in his predilection for literature by intercourse with Charles Nodier and Victor Hugo. His first work, *Les contes d'Espagne et d'Italie* (1830), revealed his poetic talent, and excited much attention and comment on account of the unbridled utterances of a fantastic and erotic imagination. His next important production, *Le spectacle dans un fauteuil* (1838), consisted of a tragical poem (*La coupe et les lèvres*), a graceful comedy or *imbroglio* (*A quoi rêvent les jeunes filles?*), and a kind of Byronic narrative in verse (*Namouna*), containing eloquent lines addressed to the Tyrolean, which were regarded by his admirers as the most classical production of the romantic school. More perhaps than any of his contemporaries he embodied in his effusions morbid and skeptical views of life, which mar to some extent the beauty of his exquisite poem *Rolla* (1835), and of his *Lettres d'un voyageur* and *Confessions d'un enfant du siècle* (1836), which latter he published after a tour in Italy in company with George Sand. Among the poems which he published in the *Revue des deux mondes* from 1835 to 1840, his ode to Malibran, his *Nuits*, *Lettre à Lamartine*, and *L'espoir en Dieu* were most admired. During the political complications in 1840 he answered Becker's German war song in regard to the Rhine with a poem entitled *Nous l'avons eu, votre Rhin Allemand*. The influence of the duke of Orleans had procured for him the office of librarian in the ministry of the interior; and he commemorated the death of that prince in 1842 in one of his most eloquent poems. He was deprived of his office after the revolution of 1848, but was restored to it after the establishment of the empire (1852), with the title of reader to the empress, and also succeeded Dupaty as a member of the academy. His *Poésies complètes* (3 vols., Paris, 1847-'9) comprise most of his poetical productions up to that period. He also wrote a great number of novelettes and tales, most of which were first published in the *Revue des deux mondes* and *Constitutionnel*, and afterward collected in 1846

and partly in 1847, and in *Contes* comprising *Mimi Perison*, *Histoire d'un morle blanc*, and *La mouche* (1854). Among his best novelettes are *Emmeline* and *Margot*. He was less successful as a dramatist; several of his theatrical pieces, however, particularly *Un caprice* (3d ed., Paris, 1848), *Il ne faut jurer de rien* (1848), and *Il faut qu'une porte soit ouverte ou fermée* (1851), were received with great favor. A number of his dramatic compositions are included in his *Comédies et proverbes* (Paris, 1840, 1848, and 1851).—PAUL EDMÉ DE, brother of the preceding, born in Paris, Nov. 7, 1804, is the author of many successful novels, as *Lauzun* (1835), *Anne de Boleyn* (1836), *Les nuits Italiennes* (1849), and *Jean le trouveur* (1849). His *Femmes de la régence* is regarded as one of his best productions, and has passed through several editions (4th ed., 1858). He has also published a great number of novelettes in the *Revue des deux mondes*, and in 1846 a translation of Gozzi's memoirs in the *National* newspaper. In 1848 he became the dramatic critic of that journal. His comedies *La revanche de Lauzun* (1836), and *Christine, roi de Suède* (1857), exhibit talent, but are deficient in dramatic effect.

MUSSULMAN and MOSLEM, corruptions of the Arabic *muslim* (pl. *muslimin*), "resigned to God," which signifies a Mohammedan. The proper plural of Mussulman is Mussulmans.

MUSTARD (It. *mostarda*), the pulverized seeds of the *sinapis alba* or white mustard, and the *S. niger* or black mustard. The name is also applied to the plants themselves, which belong to the natural order *crucifera*. Both species are indigenous to Great Britain, and are cultivated in gardens in America. The plants are annuals, and grow to a height of 3 or 4 feet, with spreading branches; they flower in the month of June. The seed vessels of the black mustard are smooth, those of the white rough and hairy. The seeds of the former are small, of a dark brown color, inodorous when whole, but when powdered and mixed with water give a strong penetrating odor and a sharp burning taste; those of the latter are larger, of a yellow color and less pungent taste. The flour of mustard is obtained by crushing and sifting both kinds of seeds, which are mixed together for this purpose. The first sifting yields what is called the impure flour of mustard, the second sifting the pure flour of mustard; the residue in the sieve is called dressings. Several peculiar chemical compounds have been extracted from the seeds of black mustard, among which are an acid called myronic, containing nitrogen and sulphur, and myrosine, which is analogous to emulsine, the albuminous constituent of almonds. These, when mixed together in cold or warm water, cause the development of the volatile oil of mustard, to which the peculiar properties of mustard are due. As heat, alcohol, and acids cause the myrosine to coagulate, and thus prevent the formation of the volatile oil, the use of hot water should be avoided in the mixing of

mustard. A fixed oil of mustard is obtained from the dressings, which is mixed with rape and other oils. In medicine the whole seeds of mustard are sometimes used as a cathartic, and pounded or broken as an emetic. The flour of mustard is especially convenient where an emetic is suddenly required, as in cases of poisoning, having a very speedy effect. The quantity given is a large teaspoonful. The powder is invaluable as a rubefacient, and mixed with water is often applied in the form of a cataplasm, acting speedily and powerfully, though great care should be taken that it does not remain on too long, as vesication with ulceration may be the result. If a very speedy effect be not required, an equal portion of wheat flour or rye meal may be mixed with the mustard. The oil of mustard is also a powerful rubefacient, and has been given internally in cases of colic, but an over-dose is extremely poisonous.—Mustard was used by the ancients only as a medicine, and is spoken of by Theophrastus, Galen, and others, by the name of *παραρτι*. Its use as a condiment is spoken of by Shakespeare in the "Taming of the Shrew," act 4, scene 8, though it does not seem to have become common until the time of George I. Its adulteration is largely practised in Great Britain—so much so, that a special establishment is now provided at Deptford for supplying the royal navy with the pure article. The substances used for its sophistication are chiefly flour, turmeric, and gypsum, turmeric improving the color, and also being a cheap substitute. The plant spoken of as mustard in the New Testament seems to have been a different plant from our mustard. The *S. Persica*, a native of Syria belonging to the genus *Salvadora*, is, it is thought, the true mustard tree of the New Testament, in whose branches the fowls of the air could find shelter.

MUTINY (Fr. *mutin*, refractory, stubborn; *mutiner*, to rise in arms). A century ago, the word mutiny was, as we learn from lexicographers, often used in describing insurrection or sedition in civil society; but it is now applied exclusively to certain offences by sailors and soldiers. Properly it is the act of numbers in resistance of authority; but by statutes, certain acts of individuals are declared to be mutiny. The act of congress of March 3, 1835, defines mutiny or revolt in the following language: "If any one or more of the crew of any American ship or vessel on the high seas, or on any other waters within the maritime and admiralty jurisdiction of the United States, shall unlawfully, wilfully, and with force or by fraud, threats, or other intimidations, usurp the command of such ship or vessel from the master or other lawful commanding officer thereof; or deprive him of his authority and command on board thereof; or resist or prevent him in the free and lawful exercise thereof; or transfer such authority and command to any other person not legally entitled thereto; every such person so offend-

ing, his aiders and abettors, shall be deemed guilty of a revolt or mutiny and felony." The same statute provides for endeavors and conspiracies to excite mutiny. In construction of the act it has been held that mere disobedience of orders by one or two of the seamen, without any attempt to excite a general resistance or disobedience, and insolent conduct or language toward the master or violence to his person, if unaccompanied by other acts showing an intention to subvert his authority as master, are not sufficient to constitute the offence of endeavoring to excite mutiny. An indictment for this crime, it is said, must set forth a confederacy of at least two of the men to refuse to do further duty, and to resist the lawful commands of the officers. The offence of making a revolt was by the act of April, 1790, punishable by death. By the act of 1835, now in force, it is punished by fine not exceeding \$2,000, and by imprisonment and confinement at hard labor for not more than 10 years, according to the nature and aggravation of the offence; while attempts to excite a mutiny are punishable by fine not exceeding \$1,000, or by imprisonment not exceeding 5 years, or by both. Mutinous conduct in the army and navy is provided for by the acts of April 10, 1806, and of April 28, 1800. By the former, "any officer or soldier who shall begin, excite, cause, or join in any mutiny or sedition, in any troop or company in the service of the United States, or in any party, post, detachment, or guard, shall suffer death, or such other punishment as by a court martial shall be inflicted." Under the latter, "if any person in the navy shall make, or attempt to make, any mutinous assembly, he shall, on conviction thereof by a court martial, suffer death."

MUTTRA, a British district of the N. W. provinces, Hindostan, between lat. 27° 14' and 27° 58' N., and long. 77° 20' and 78° 34' E.; area, 1,607 sq. m.; pop. in 1858, 862,909, of whom about 70,000 were Mohammedans. The principal river is the Jumna, which flows for 95 m. within or along the boundaries of the district, but is not navigable in this part of its course except during the wet season. The surface of the district is almost uniformly level, and the soil of various qualities, but generally fertile. The climate is extremely hot in spring, but tempered a little in summer by the periodical rains. Wheat, barley, millet, pulse, oil seeds, sugar, indigo, cotton, tobacco, and opium are produced. The district was ceded to the East India company by the Mahrattas in 1808.—**MUTTRA**, the capital of the preceding district, is situated on the right (W.) bank of the Jumna, 97 m. S. E. from Delhi; pop. 65,749. It is picturesquely built on high ground in the form of a crescent, and was once well fortified. Flights of stone steps, or ghauts, adorned with temples, lead down to the river, which is accounted sacred by the Hindoos, and every day crowds of devotees frequent its banks to perform their religious rites. The streets are steep, narrow,

and dirty, and rendered more difficult by deep ravines which run through the town. There are some striking ruined buildings, among which is a fort, having on its roof an observatory with astronomical instruments. One of the most beautiful edifices is a temple and dwelling house together, built by a former treasurer of the state of Gwalior, and approached through a richly carved gateway. The British have extensive cantonments about a mile distant. Muttra is held in great reverence by the Hindoos as the birthplace of Krishna, and is overrun with sacred monkeys, bulls, parquets, and peacocks, which are fed and protected, but allowed to go at large in the streets. The wealth and importance of the place were formerly much greater than at present. Mahmoud of Ghuznee sacked it in 1017, and carried off or destroyed an enormous amount of treasure. Among other rich specimens of handicraft, he found 5 idols of gold with eyes of rubies, and 100 idols of silver, each as large as a camel could carry. At the commencement of the present century the town was taken by Sindia, who bestowed it on the French adventurer Perron; and in 1803 it was occupied by the British troops, and soon afterward ceded to the East India company by the treaty of Serjee Anjengaum.

MUZIANO, GIROLAMO, an Italian painter and architect, born in Acquafredda, near Brescia, in 1528, died in Rome in 1590 or 1592. He established himself in Rome about the middle of the 16th century, and became known as a landscape painter. His historical pieces were also popular, and one of them, a "Resurrection of Lazarus," painted for the church of Sta. Maria Maggiore, was highly commended by Michel Angelo, who called Muziano one of the greatest masters of the age. The churches of Rome and other Italian cities contain many fine works by him in oil and fresco; and there is also a celebrated "Christ Washing the Feet of his Disciples" in the cathedral of Rheims, which has been engraved by Desplaces. He was almost equally celebrated as a mosaic worker. His chief architectural work is the chapel of Gregory XIII. in St. Peter's. He was instrumental in founding the academy of St. Luke at Rome, the brief for the establishment of which he procured from Gregory XIII. Many of his drawings and pictures have been engraved.

MUZZEY, ARTEMAS BOWERS, an American clergyman and author, born in Lexington, Mass., Sept. 21, 1802. He was graduated at Harvard college in 1824, and at the Cambridge divinity school in 1828, and was ordained pastor of the Unitarian society in Framingham, Mass., June 10, 1830. He resigned this position in May, 1833, and became pastor successively of the Unitarian churches in Cambridgeport, Jan. 1, 1834; Lee street, Cambridge, in July, 1846; Concord, N. H., in March, 1854; and Newburyport, Mass., Sept. 8, 1857. He has published "The Young Man's Friend" (1836); "Sunday School Guide" (1837); "Mor-

al Teacher" (1839); "The Young Maiden" (1840), which has passed through 16 editions; "Man a Soul" (1842); "The Fireside" (1849); tracts for the American Unitarian association; three lectures before the American institute of instruction; a "Lecture on Books and Reading" before the young men of Concord, N. H.; and reports on common schools and Sunday schools, beside many sermons and essays.

MYCALE (now *Samsun*), a mountain in the south of Ionia in Asia Minor. It is the W. extremity of Mount Mesogis, and runs out into the sea in a promontory called Mycale or Trogylium (now Cape S. Maria), directly opposite Samos, from which it is separated by a strait $\frac{1}{2}$ of a mile in width. This strait was the scene of the great naval victory of the Greeks under Leotychides and Xanthippus over the Persian fleet, Sept. 25, 479 B. C. On the N. side of the promontory was the temple of Neptune, where the Panionic festival of the Ionian confederacy was held. On or near the promontory, there appears to have been a city of the same name.

MYCENÆ, or MYCENÆ, a city of ancient Greece, situated on a rocky hill at the N. E. extremity of the plain of Argos. It is said to have been founded by Perseus, and its massive walls were deemed the work of the Cyclops. It was the favorite residence of the Pelopides, and during the reign of Agamemnon was considered the principal city of Greece. From the period of the Dorian conquest its importance declined; but it still maintained its independence, and in the Persian war contributed its quota of troops. This brought upon it the enmity of the other Argives, who in 468 B. C. laid siege to Mycenæ, reduced it by famine, and destroyed it. It was never rebuilt, but its remains, near the modern village of Kharvati, are among the grandest and most interesting of the antiquities of Greece. Part of the walls of the acropolis, to the height in some places of 15 or 20 feet, are still standing, and at their N. W. angle may yet be seen the great entrance to the fortress, styled the "gate of lions" from the two lions sculptured in the stone above. The most remarkable of its other antiquities is the subterranean vault commonly called "the treasury of Atreus," consisting of two chambers, the larger of which is of conical form, 40 feet high and 50 feet broad, and has beside its doorway two columns with arabesque ornaments.

MYCONI (anc. *Myconus*), an island of Greece, in the Ægean sea, one of the Cyclades, and lying E. of Delos and N. of Naxos, about 10 m. long and 6 m. wide; pop. about 6,000. Its highest summit has two peaks, whence Pliny calls it *dimastus*. Corn, wine, cotton, and figs are produced. In ancient times it was famous for the number of bald persons among its inhabitants.

MYERS, PETER HAMILTON, an American novelist, born in Herkimer, Herkimer co., N. Y., in Aug. 1812. He has written several American historical romances: "The First of

the Knickerbockers, a Tale of 1673" (New York, 1848); "The Young Patroon, or Christmas in 1690" (1849); "The King of the Hurons" (1850), republished in England under the title of "Blanche Montaigne;" and "The Prisoner of the Border, a Tale of 1838" (1857). He has also written five prize tales, for three of which, "Bell Brandon, or the Great Kentrip Estate," "The Miser's Heir, or the Young Millionaire," and "The Van Veldens," he received prizes of \$200 each. Mr. Myers in 1841 delivered a poem on "Science" before the Englossian society of Hobart Free college, Geneva, N. Y. He is by profession a lawyer, and resides in Brooklyn, N. Y.

MYLNE, ROBERT, a British architect, born in Edinburgh in 1734, died in London, May 5, 1811. In his youth he visited various parts of Italy, and at Rome gained the first prize in architecture at the academy of St. Luke, of which he was elected a member. He afterward settled in London, where he was the architect of Blackfriars' bridge, built at a cost of nearly £300,000. Among the various edifices which he repaired are Rochester cathedral and Greenwich hospital. For nearly 60 years prior to his death he was engineer to the New river water works company. His remains were interred in St. Paul's beside those of Sir Christopher Wren.

MYLODON (Gr. *μύλη*, mill, and *οδους*, tooth), a genus of gigantic fossil edentates established by Prof. Owen, and closely allied to the sloth, resembling megalonyx and megatherium; it is described in detail and figured in a monograph by Prof. Owen (London, 1842), to which the reader is referred for most of what is known concerning this animal and the megatherioid quadrupeds in general. The mylodon has the heavy form of the megatherium, with a dentition resembling that of the megalonyx; the molars are $\frac{3}{2}$, and are worn into flat surfaces; in the upper jaw, the 1st is subelliptical and separated from the rest, the 2d elliptical, and the others triangular, with the internal surface grooved; in the lower jaw, the 1st is elliptical, the 3d quadrangular, and the last the largest and bilobed, and the symphysis stronger than in the megalonyx. The head resembles that of the megatherium in its form, and has a strong descending process of the zygomatic arch; the extremities are equal, the anterior 5-toed and the posterior 4-toed; the 2 external fingers are without nails, and the others have large semi-conical and unequal claws; the acromion and coracoid are united, the radius turns around the ulna, the tibia and fibula are distinct, the heel bone long and large as in other megatherioids. (See MEGALONYX, and MEGATHERIUM.) The *M. Darwinii* (Owen) was discovered by Mr. Darwin in northern Patagonia; the symphysis of the lower jaw is long and narrow, with the 2d molar subelliptical, and the last with 2 furrows, of which the internal is angular; it is found from the pampas of Brazil southward. The *M. Harlani* (Owen) has the symphysis shorter and wider, the 2d

molar square, and the last with 8 grooves, the internal one biangular; this has been found in Kentucky, Mississippi, Missouri, South Carolina, and Oregon. The *M. robustus* (Owen) is characterized by a short and wide symphysis, with the 2d molar subtriangular, and the last with 8 grooves, of which the internal is rounded. A fine and nearly complete skeleton of this species is now in the museum of the London college of surgeons, the one which forms the subject of the monograph of Owen above referred to; it was discovered in 1841 in the fluviatile deposits about 20 miles north of Buenos Ayres, recently elevated above the level of the sea. The skeleton is very robust; the trunk, shorter than that of the hippopotamus, ends in a pelvis as wide as and deeper than that of the elephant; the hind limbs short and massive, with feet as long as the thigh bones, set at right angles to the leg, and with the sole turned slightly inward; the tail as long as the hind limbs, very thick, and affording a firm support in the semi-erect position; the chest long and large, protected by 16 pairs of ribs, broad and strongly attached to a well developed sternum; the scapulae unusually broad; arm bones thick and short, with strong processes for muscles; the bones of the forearm longer than those of the leg; the skull smaller than that of the ox, but long, narrow, with a truncated muzzle, and supported by a short neck of 7 vertebrae; dorsal vertebrae 16, with broad and high spinous processes nearly equal and having a uniform backward inclination. Such proportions are found in no living animals, and only in the megatherioids among fossils. The skull presented 2 extensive fractures, from which the animal had recovered; the air cells extend from the frontal and ethmoidal sinuses into the cranial bones, separating the 2 tables of the skull sometimes for the extent of 2 inches, forming a great protection against injury from falling limbs of trees. They were probably peaceful animals like the existing sloths, though able to inflict severe wounds by their sharp and heavy claws; the strength of the edentate muscles is very great, and must have been immense in all the megatherioids. While presenting the closest affinity to the small arboreal sloths, the mylodon, with its claw-armed inner toes, had the outer thick and stunted, and evidently enveloped in a kind of hoof, giving the power of standing and walking firmly as well as digging and seizing—in this respect marking a transition between edentates and pachyderms. It is now generally admitted that this animal commenced the process of prostrating trees by scratching away the soil from their roots, and loosening them from their attachments; then, seizing the branches or trunk, and supported on the hind limbs and tail, it swayed the tree to and fro like a mighty wrestler, and soon brought it to the ground to be stripped at its leisure; in case of meeting a tree too large to be uprooted, it is probable that some of the smaller species,

as indicated by the inward turning of the soles, possessed the faculty of climbing to the larger branches within reach of the tempting foliage. In regard to the means of stripping off leaves, Prof. Owen, from the cavity in the mastoid process for the articulation of the hyoid bone, and the large size of the anterior condyloid foramina whence issue the motor nerves, maintains that there was a remarkable development of the tongue; this is also indicated by the broad, smooth, concave surface of the symphysis of the lower jaw, which, with the absence of incisors, offered no obstacle to its free motions, and provided space for it when retracted; the megatherium had a short proboscis, prehensile lips, and a smaller tongue in a narrower mouth; the elephant has a maximum proboscis, the giraffe a maximum tongue, the megatherium being intermediate; the mylodon, having no proboscis, had a largely developed tongue for stripping off foliage, contrasting in this respect with the almost tongueless elephant. While the megatherium may have measured 18 feet from the fore part of the skull to the end of the tail, following the curve of the spine, the mylodon measured only 11 feet; other measurements in these animals respectively were: circumference at pelvis $14\frac{1}{2}$ and $9\frac{1}{2}$ feet; length of skull $2\frac{1}{2}$ and $1\frac{1}{2}$ feet, greatest width $1\frac{1}{2}$ and $\frac{1}{2}$ foot; length of lower jaw $25\frac{1}{2}$ and $15\frac{1}{2}$ inches, width at symphysis $5\frac{1}{2}$ and $5\frac{1}{2}$ inches; length of anterior limb 10 and $4\frac{1}{2}$ feet; clavicle 15 and $8\frac{1}{2}$ inches, humerus $2\frac{1}{2}$ and $1\frac{1}{2}$ feet, ulna $25\frac{1}{2}$ and $14\frac{1}{2}$ inches, radius 26 and 11 inches; fore foot $81\frac{1}{2}$ and 14 inches long, and $14\frac{1}{2}$ and $8\frac{1}{2}$ wide; middle and longest claw $10\frac{1}{2}$ and $5\frac{1}{2}$ inches; width of pelvis 61 and 41 inches; length of femur $28\frac{1}{2}$ and 19 inches, circumference over great trochanter $8\frac{1}{2}$ and $2\frac{1}{2}$ feet, and width at same point 16 and 9 inches; tibia 22 and $8\frac{1}{2}$ inches; length of hind foot $34\frac{1}{2}$ and 19 inches, width 12 and $6\frac{1}{2}$; heel bone 17 and $7\frac{1}{2}$ inches; middle and largest claw $9\frac{1}{2}$ and $5\frac{1}{2}$ inches; and width of largest vertebra of tail 21 and $10\frac{1}{2}$ inches.—The scelidotherium (Gr. *σκελεις*, hind leg, and *θηριον*, animal) is another extinct megatherioid, remarkable for the size of the hind limbs; a nearly entire cranium shows the essential characters of the sloth's skull, with the mylodontal modifications of the complete zygoma and shape of the lower jaw; the teeth were $\frac{3}{4}$ - $\frac{1}{2}$, the upper triangular; the form was massive. Pictet mentions 7 species, varying in size from a hog to an ox, which lived in South America during the diluvial epoch. Some other genera have been described by Owen, Pictet, and Leidy.

MYNSTER, JACOB PEDER, a Danish theologian, born in Copenhagen, Nov. 8, 1775, died there, Jan. 30, 1854. He was educated at the university of his native city, was employed for some time in teaching, and became in 1801 pastor in Seeland. In 1811 he was appointed assistant minister of the principal church of Copenhagen, in 1828 preacher to the court and the royal family, and in 1834 bishop of Seeland.

His writings comprise a great number of sermons, dissertations introductory to the study of the New Testament and on other biblical subjects, and several works on doctrinal theology. His admirable "Ordination Sermons" and other of his works have been translated into German. An edition of his miscellaneous publications (*Blandede Skrifter*), begun in 1852, was completed in 6 vols. in 1856.

MYRIAPODS. See CENTIPEDE.

MYRMELEON (Linn.), the ant lion or lion ant, a genus of neuropterous insects, one of the species of which has become celebrated for the singular manner in which the larva obtains its living prey. The perfect insect resembles a small dragon fly, has a good power of flight, and is generally found in the warmer parts of southern Europe. The larva of *M. formicarium* (Linn.) is about $\frac{1}{4}$ inch long, of an oval depressed form, and grayish sandy color; the small head is armed with 2 strong and long mandibles, serrated and pointed, with which it seizes and sucks the juices of its prey. The powers of locomotion being small, it has recourse to artifice to entrap insects; it makes a funnel-shaped excavation in sandy soil, with loose and crumbling sides, and buries itself, all but the head, at the bottom, waiting for a victim; if an ant or small insect approaches the edge, the sand gives way and it rolls down within reach of the expectant jaws; after the body has been drained it is cast out by a toss of the head; if the insect be large or likely to escape, the ant lion throws repeated showers of sand upon it by means of the head, until it falls exhausted and defenceless to the bottom of the pitfall. But sometimes a revengeful wasp, well armed bee, or mail-clad beetle falls into the snare, and the sting of the one or the powerful jaws of the other often prove fatal to the ant lion. The larva state continues about 2 years, when a cocoon is spun, in which it is changed into an inactive nymph; the perfect insect comes out in 2 or 3 weeks, and lays the eggs for a new brood in dry and sandy places suited for the operations of the larvæ. Many other species are described.

MYRMIDONES, an ancient Achæan race of Phthiotis in Thessaly. According to the mythological account, they originally came from Ægina, where, at the request of Æacus, Jupiter changed all the ants (*μυρμηκες*) of the island into men, who from their origin received the name of Myrmidones. They subsequently followed Peleus into Thessaly, accompanied his son Achilles in the expedition against Troy, and at a later period disappeared from history. Other accounts make them the descendants of Myrmidon, a son of Jupiter and Eurymedusa, whom the god deceived in the disguise of an ant. Modern critics suppose that they were a Thessalian colony, which emigrated to Ægina. From them is derived the word myrmidons, designating a band of rough soldiers or ruffianly marauders devoted to the will of a leader.

MYRON, a Greek sculptor, born in Eleuthera, in Boeotia, about 480 B. C. He was remarkable for his versatility, and beside representing the human figure in its most difficult attitudes, he modelled animals with success. His masterpieces were nearly all in bronze. The most celebrated were his *Discobolus*, or quoit player, and his "Cow." There are several marble *Discoboli* still extant, copies of the original. One of them is in the Towneley gallery of the British museum, another in the Villa Massimi at Rome, and a third in the museum of the Vatican. The cow of Myron, which stood on a marble pedestal in the agora at Athens, was an object of even more admiration than the quoit player. It was afterward removed to the temple of Pax at Rome. Of Myron's other works, perhaps the most famous were his colossal statues of Jupiter, Minerva, and Hercules at Samos, which were carried off by Mark Antony. Augustus restored Minerva and Hercules to the Samians, retaining only Jupiter, which he placed in the capitol.

MYRRH (Gr. *μυρρ*, to trickle), a gum resin exuded spontaneously from the bark of the *balanodendron myrrha*. It was known in commerce at a very early period, frequent allusion being made to it in the Old and New Testaments; but the tree which afforded it, though described by Dioscorides, was not fully known till 1825, when Ehrenberg brought a specimen of it from the borders of Arabia Felix. The best myrrh was formerly imported from Turkey, but all qualities are now brought from India. It is obtained in agglomerated tears of various sizes, of a reddish brown or pale reddish yellow color, semi-transparent, with a dull, splintery kind of fracture. It has a pungent balsamic odor, and a bitter aromatic taste. It is readily dissolved by the alkalies. Water dissolves the gum principally, while alcohol and ether take up the volatile oil and resin. The best quality consists of 34 per cent. of resin and 66 of gum. Samples analyzed by Brandes and Braconnot gave the following results:

	Brandes, Braconnot.	
Volatile oil.....	9.00	9.5
Resin.....	37.50	38.0
Gum: { soluble.....	54.38	46.0
{ insoluble.....	9.33	12.0
Salts: benzoates, malates, phosphates, sulphates, and acetates of potassa and lime.	1.36
Impurities.....	1.00	16.5
Loss.....	2.94	
Total.....	100.00	100.0

Myrrh is employed only in medicine; it is useful in disordered conditions of the digestive organs and as an expectorant, externally as a dentifrice, and in the form of tincture as a gargle for ulceration of the throat. It is also an ingredient in some plasters.

MYRTLE (Gr. *μύρτος*), a beautiful plant, native of Persia, but naturalized in the south of Europe, being now abundant on the sea coast from Marseilles to Genoa, and throughout Italy. The leaves of the myrtle are sempervirent, of a rich dark green tint, ovate, lanceolate, or

acute. They are covered with pellucid dots, which secrete a highly fragrant volatile oil. From the axils of the leaf issues a solitary pedicel with 2 linear bractioles, and bearing on its summit a single flower with a 5-cleft calyx, 5 white petals, numerous stamens, and one style, which is succeeded by a somewhat globose berry of 2 to 3 cells. The common myrtle (*myrtus communis*, Linn.), the most northern species of the order, is the type of the natural order *myrtaceae*, which comprises a great many genera, natives of hot countries both within and without the tropics. A woody texture belongs to all the myrtle tribe, but the habits this assumes vary greatly, as De Candolle observes, from the *M. nummularia*, which spreads over the soil in the Falkland islands as the thyme does in Europe, to the immense *eucalypti* of Australia, which are among the most gigantic trees of that continent. The common myrtle in its usual size and height gives us however a good idea of the average size of the majority of the *myrtaceae*. Some myrtles in the vicinity of London have been known as trained plants to reach a height of 10 to 20 feet, and an equal width. At Cobham hall in Kent are several specimens 30 feet high. The myrtle cannot, however, be considered as more than a half-hardy shrub in Great Britain. It was introduced into England in the 16th century; Gerard knew the myrtle in cultivation as early as 1597. Pliny informs us that it was a rare plant in Italy in his day; he, however, makes mention of 11 sorts, and remarks that the most odoriferous grew in Egypt. In the United States the myrtle is usually treated as a pot plant, or when large grown in tubs, for removal into the cellar on approach of winter. De Candolle's arrangement of the kinds of myrtle is considered the best. According to that, there are two species, viz.: 1, *M. melanocarpa*, or black-fruited, common in gardens, where are varieties of it with double flowers and variegated foliage, and also embracing the broad-leaved or Roman myrtle, the box-leaved, the upright or Italian, the orange-leaved, the acute-leaved or Portugal, the broad-leaved Dutch, and the thyme-leaved myrtles; and 2, the white-berried, *M. leucocarpa*, native of Greece and the Balearic isles, the fruit of which is rather large, edible, with a grateful smell and taste. There are several striped-leaved sorts known in Europe, of much beauty. All the varieties propagate readily by cuttings and from seeds. The cuttings should be struck in sand, or peat and sand, and covered in the process with a bell glass.—The myrtle was well known to the ancients, and was held in high esteem for its beauty, supposed virtues, and medicinal qualities. It was employed as a symbol of authority, and entwined with laurel for wreaths in the triumphs of bloodless victory and of the Olympic and other games. The buds and berries were used as spices, and the latter are still employed in Tuscany as a substitute for pepper. A wine made from the myrtle was called *myrtidamum*. In Greece the

berries are administered to little children for treatment of diarrhoea. The *eau d'ange*, a sort of perfume sold in France, is distilled from the flowers. Medicinal qualities reside in the astringent nature of the various portions of the plant; and in Greece, Italy, and the south of France the bark is used in tanning.—There are some other species occasionally met with in collections, such as *M. tomentosa*, a native of China, with rose-colored flowers, and *M. myrsinoides*, a native of the colder parts of Peru. The order of myrtleworks (*myrtaceae*) is of much interest, embracing as it does the pomegranate, the guava, the clove, the pimento or allspice, and many trees producing valuable gums and important astringents.

MYSIA, in ancient geography, a N. W. division of Asia Minor, the boundaries of which greatly varied at different periods. In the time of the early Roman emperors it was bounded N. by the Propontis (sea of Marmora), E. in part by the Bithynian Olympus, S. E. by Phrygia, S. by Lydia, W. by the *Ægean*, and N. W. by the Hellespont (strait of Dardanelles). It thus included, among other territories, those of Troas in the N. W., and Tenthraia (which included Pergamus), as well as the Grecian coast land of *Æolis*, in the S. W. Mysia was for the most part mountainous, the principal ranges within its boundaries being Mt. Ida in Troas, Mt. Temnus, which extended from the former to the borders of Phrygia, dividing the country into two unequal parts, and Mt. Olympus on the north-eastern or Bithynian border. Of the principal rivers, the Calcas and Evenus flowed into the Elaitic gulf, on the S. W. corner; the Sainois into the *Ægean*, N. of Cape Lectum; the Scamander and Simois, renowned in Trojan legends, into the Hellespont, near Cape Sigæum; the Granicus, on the banks of which Alexander the Great achieved his first victory over the Persians (334 B. C.), the *Æsepus*, Tarsius, *Maecæstus*, and *Rhyndacus*, into the Propontis. The largest gulf was that of *Adramyttium* (now *Adramyti*) on the *Ægean*, opposite the island of *Lesbos*. Mysia is more renowned in legendary traditions than in history, the chief interest attaching to the territories of Troas, Pergamus, and the *Æolian* confederacy. Having been successively under the dominion of the Persians, of Alexander the Great, his general *Lysimachus*, and the *Seleucids*, it was assigned by the Romans, after their victory over *Antiochus the Great* (190), to the new kingdom of Pergamus, which had previously been formed from one of its parts, and with the whole of that kingdom was bequeathed to the Roman republic by King *Attalus III.*, thus becoming a part of the proconsular province of Asia (133).

MYSORE, a semi-independent native state in the S. of India, within the geographical limits of the presidency of Madras, situated between lat. 11° and 15° N.; area, 30,886 sq. m.; pop. 8,460,696. The state is divided into 3 districts, Chitteldroog, Bednore, and Seringapatam; the chief towns are Bangalore, Mysore,

and Seringapatam. The country consists of a table-land elevated about 3,000 feet above the level of the sea. The principal rivers are the Cavery, Tumbudra, Vedawati, and the N. and S. Pennar. There are no natural lakes, but many large tanks and artificial reservoirs in the high grounds. Some of the mountains attain a height of 6,000 feet above the sea. The level of the table-land is interrupted in places by large masses of granite, rounded in their outlines, standing single or in clusters. The climate is healthful. Mysore not only produces the grains, vegetables, and fruits of other parts of India, but also many of those belonging to the temperate regions. A considerable portion of the surface is covered with jungle, but the country appears to have been formerly in a much higher state of cultivation than at present. Rice, sugar cane, *raggy*, a species of coarse grain, and wheat are the chief crops raised. The betel tree and the plant from which castor oil is made thrive well. Carbonate of soda, salt, and iron are found. The inhabitants are principally Hindoos, though there are many Mohammedans. Coarse blankets, woollen carpets, shawls, and cottons are manufactured.—Mysore is mentioned in the Hindoo mythological writings; but the earliest authentic history of the country which we possess commences with the Mohammedan invasion in 1326, when the kingdom was incorporated with the empire of Delhi. The affairs of that empire soon afterward falling into confusion, Mysore was lost, and some Hindoos escaping from Mohammedan persecution in the N. founded a city on the banks of the Tumbudra, which is now called Bijayanagai. This new state comprised nearly the whole of Mysore and part of the Carnati; but in 1565 its ruler, Ram Rajah, was defeated and slain by the army of a Mohammedan confederation, and his capital taken and depopulated. A Mysorean chief, named Rajah Wadeyar, acquired possession of the fort and island of Seringapatam, and his successors, by a career of aggression, toward the close of the 17th century, had extended their authority over the whole table-land of Mysore. In 1781 the minister deposed the rajah, and in 1749 Hyder Ali made his appearance as a volunteer in the army of Mysore. Upon the death of Tippoo Sultan in 1799, the British annexed a considerable portion of his dominions to their Indian possessions, and allotted the territory now known as Mysore to the descendant of the rajah who had been supplanted by Hyder; but though the government of Mysore is nominally in the hands of a native prince, it is in reality vested in the British resident at his court, appointed under the Madras presidency. (See HYDER ALI, TIPPOT SULTAN, and SERINGAPATAM.)—Mysore, the capital, is situated in lat. 13° 19' N. and long. 76° 42' E.; pop. 54,729. It is enclosed with an earth wall. The fort, which contains the rajah's palace, is a European structure. The principal traders and bankers reside in it.

MYSTERIES (Gr. *μυστήρια*, from *μυσ*, to shut the lips, to keep silence), ceremonies in ancient religions to which only the initiated were admitted. Little is certain concerning them except the fact of their existence and importance, and their prominence in modern speculations on the history of ancient religions. They may be obscurely traced in the early Orient, in the rites of Isis and Osiris in Egypt, in the Persian Mithraic solemnities, and in the festivals introduced into Greece with the worship of Bacchus and Cybele; the rites of Hellenic worship culminated in them in diverse forms and places, from the traditional age of the Samothracian divinities till the time of the Neo-Platonic philosophers; and they lingered through the decline of Rome, and perhaps left their traces in the ceremonies of free masonry. Hellenic paganism may be said to have concentrated in the Eleusinian and other mysteries the essence of its faith, and there surrounded it with the most splendid symbolical ritual. They were called indiscriminately in Greek *μυστήρια*, *orgia*, and *τελεται*, and in Latin *initia*, with reference respectively to the mystical and secret nature of the ceremonies, to the enthusiasm which they inspired in the votaries, to the edification which resulted from them, and to the initiation which they promised into a new life. They consisted, in general, of rites of purification and expiation, of sacrifices and processions, of ecstatic or orgiastic songs and dances, of nocturnal festivals fit to impress the imagination, and of spectacles designed to excite the most diverse emotions, terror and trust, sorrow and joy, hope and despair. The principal subject of the representations was the legends of particular divinities, their abode and passion on the earth, their descent into Hades and death, their return and resurrection, thus symbolizing at once human destiny and the order of nature. The celebration was chiefly by symbolical acts and spectacles; yet sacred, mystical words, formulas, fragments of liturgies, or hymns were also employed. There were also certain objects, with which occult meanings, that were imparted to the initiated, were associated, or which were used in the various ceremonies in the ascending scale of initiation, such as the *phallus*, *ciste*, *cyceon*, *cistus*, *calathus*, *thyrsus*, flambeau, serpent, tympanum, &c., according to the different mysteries. That any esoteric abstract dogmas were thus perpetuated, that any superior doctrine, cosmological, physical, metaphysical, or moral, was communicated to the initiated, is according to the best contemporary critics not proven, though the reverse was universally supposed by the scholars of the last century. They probably gave a figurative and symbolical instead of a direct and dogmatic instruction. Founded on the adoration of nature, the forces and phenomena of which were conceived by the imagination and transformed into the characters of the mythology, they appealed to the eye rather than the reason. They were de-

signed by imposing and mysterious external splendor to create more vital and effective impressions from the symbols, sentiments, and ideas which belonged to the current system of mythical dogma and legend. The sacred phrases, the *απορρητα* concerning which silence was imposed, were themselves symbolical legends, and not statements of speculative truths. The most diverse theories have been suggested concerning the origin of the Hellenic mysteries. According to the older critics, as Warburton, Faber, St. Croix, Schelling, and Creuzer, they were the ceremonies of a secret order, possessing a higher and peculiar wisdom, which was derived either from the Hebrew revelation through Phœnician colonization, or from an original revelation to mankind through Indian and Egyptian traditions. Creuzer supposes them to have been introduced at the dawn of Greek civilization, to which they furnished the religious impulse, to have been originally the public religion, but after the modifications caused by Hellenic hero worship to have been transformed into secret rites, in connection with which were preserved, veiled in symbols and legends, the higher meanings of the mythology, which were finally interpreted in abstract formulas by the Neo-Platonic philosophers. On the other hand, Voss maintained that the mysteries were founded by priests with the design of changing the genius of the national religion by innovations from the East or by their own inventions, and that they thus embodied rationalistic improvements and an artificial symbolism instead of older traditions. Lobeck attributes their origin to the *sacra gentilitia*, the private religious ceremonials of families, tribes, corporations, which were exclusive rather than secret, possessing no peculiar theological or moral doctrines, and attaining to national eminence only by extraordinary ritual splendor. The latest and most elaborate researches on the subject are by Preller, who refers them ultimately to the worship of the infernal divinities in the Pelasgic period, the transformation of which into mysteries was rather due to germs of mysticism contained in itself than to persecution by Hellenic conquerors. The antagonism of the mystical to the mythical cultus he founds on the ethnological distinction between the Pelasgi and the Hellenes, the former of whom opposed to the Homeric anthropomorphism a religion of symbols and allegories, which was preserved in the mysteries, and in which polytheism approached nearest to the ideas which were to triumph in Christianity. Thus originated, they borrowed divers oriental elements from the Orphic priesthood, from the Egyptian worship of Isis and Serapis and the Persian worship of Mithra, combining the superstitions of the East and the West, the excesses of religious emotion and philosophical speculation, astrology, magic, and finally Neo-Platonic theurgy and ecstasy.—The oldest of the Hellenic mysteries are believed to be those of the Cabiri in Samothrace and Lemnos, which were renowned

through the whole period of pagan antiquity. Though they were only less august than the Eleusinian, nothing is certain concerning them, and even the names of the divinities are known to us only by the profanation of Mnaseas. According to Schelling, the Cabiri were remotely of Hebrew origin, and formed a council of gods in an ascending scale, terminating in the Supreme Being as unity, who combined together in a symbolical creation of the world by a sort of magical operation, in which the initiated also took part. The object of the mysteries was to exalt the initiated to Cabiric dignity. The harmonious motions of the planets emblemize this union of gods and men. Welcker supposed that they were instituted to celebrate fire as the principle of the universe, Faber that they commemorated mutilated traditions of the deluge; Müller found in the Cabiri the symbols of an eternal creator, an eternal destroyer, and a delusive and ever changing nature; Maury and others believe them to have been the demiurgic divinities of Phœnician navigators; and Finnur Magnusson attempts to trace a connection between them and the kobolds of the northern mythology.—The Eleusinian were the most venerable of the mysteries, and in every period of classical antiquity commanded the homage alike of the most distinguished poets, philosophers, historians, and statesmen. All the resources of art were employed to contribute to their splendor. "Happy," says Pindar, "is he who has beheld them, and descends beneath the hollow earth; he knows the end, he knows the divine origin of life." They comprised a long series of ceremonies, concluding with complete initiation or perfection. The fundamental legend, on which the ritual was founded, was the search of the goddess Ceres for her daughter Proserpine, her sorrows and her joys, her descent into Hades, and her return into the realm of light. The rites were thought to prefigure the scenes of a future life. The same symbol was the foundation of the Thesmophoria, which were not like the Eleusinia a local institution, and which honored Ceres especially in the character of lawgiver; they were celebrated exclusively by married women. The Eleusinia dwelt on the changes of the seed of corn under the figure of the loss of Proserpine, and her ultimate return to her searching mother, vicissitudes which symbolize the course of nature and the destiny of the soul; the Thesmophoria were occupied rather with the mother than daughter, and celebrated the maternity of the goddess of the earth. It is probable that initiation into the Thesmophoria was designed to protect against the dangers of childbirth, as the Eleusinia protected against the perils of the lower world, and the Samothracian against the perils of the sea.—The Orphic and Dionysiac mysteries prevailed from the time of the Pisistratidæ, and exerted a powerful influence on the religious institutions and life of antiquity. They seem to have designed a reformation

of the popular religion. Founded upon the worship of the Thracian Dionysus or Bacchus, who was the personification at once of rapturous pleasure and of deep sorrow for human miseries, unlike the earlier popular Dionysia they tended to ascetic rather than orgiastic practices. Christian priests and philosophers of the Alexandrian school ascribed to the Orphic fraternity a complete system of mystical doctrine, but little of the literature in which this was embodied is so ancient as the time of Plato. It is certain, however, that there was a union of the Pythagorean and Orphic associations after the expulsion of the former from Magna Græcia, that an Orphic theogony was in vogue quite distinct from that of Homer and Hesiod prior to the Persian war, and that more hopeful views of the destiny of the soul were entertained, founded upon the expected succession of Bacchus to Jupiter in the government of the world, and the consequent restoration of the golden age. The Orphic mysteries, unlike those that were more ancient and popular, were specially designed for doctrinal inculcation. Other mysteries were those of Zeus or Jupiter in Crete, of Hera or Juno in Argolis, of Athena or Minerva in Athens, of Artemis or Diana in Arcadia, of Hecate in Ægina, and of Rhea in Phrygia. The worship of the last under different names prevailed in divers forms and places in Greece and the East, and was associated with the orgiastic rites of the Corybantes.—More important were the Persian and Roman mysteries of Mithra, who appears in the Zend-Avesta as the chief of the izeds or angels, as the conqueror of tyrants and demons, giving safety to towns and fertility to lands, as the genius of love and truth, and mediator between Ormuzd and men. He resembles the demiurgic Eros of the theogony of Hesiod, and his origin has been referred to the Assyrian Mylitta or Alitta, the goddess of night, destiny, and fortune. She was the mother of two divinities, Baab Mylitta and Ahriman, and was herself confounded with the first, whose name was changed by the Persians into Mithra, and who is therefore sometimes represented as feminine. Little is known of Mithraicæism till it appeared in Rome as a mysterious and secret worship about the beginning of the 2d Christian century, from which date memorials of it remain. It was propagated by Chaldean and Syrian priests, who spread themselves throughout the empire and were received with great favor, being most honored in the age of the Antonines. The austerity of the doctrine of the Mithraic mysteries, the real perils of initiation which neophytes were obliged to encounter, the title of soldier of Mithra which was bestowed upon them, and the crowns which were offered to them after the combats preceding every grade of advancement, were among the peculiarities which gave to these rites a military and bellicose character. There is evidence that the Roman soldiers eagerly sought initiation into them. According to some authors, the Mithraic

doctrine was derived from the astronomical religion of the Chaldeans, and its fundamental dogma was the transmigration of souls under the influence of the 7 planets, over whose operations Mithra presided. The design of the solemnities was by purification to render his votaries worthy of admission into the seventh heaven. The initiated were subjected to the severest trials, to celibacy, fasting, and other practices which were probably adopted from the Christian religion. The whole fraternity was divided into 7 classes or grades, which were named successively soldiers, lions, hyænas, &c., after animals sacred to the god. Each class was distinguished by a peculiar costume and offered peculiar sacrifices, which were sometimes human victims. The sacrifice of the bull was characteristic of his worship. On the monuments which have been found in Italy, the Tyrol, and other parts of Europe, inscribed *Deo Mithra Soli Inviolato*, Mithra is usually represented as a young man, in a flowing robe, surrounded with mystical figures, seated on a bull, which he is pressing down, or into which he is plunging the sacrificial knife. A dog, a serpent, a scorpion, and a lion are arranged near him. Nothing is certain concerning the signification of this scene. By an ingenious symbolism, founded on the Assyrian astronomical and cosmological theories, Lajard arbitrarily develops the Mithraic theology, which he regards as the foundation of the religious doctrines of antiquity from India to Rome. Tertullian and other fathers of the church discovered a resemblance between several of the Mithraic and Christian dogmas and ceremonies. During the decline of paganism the mysteries of Mithra were combined with the theurgic doctrines of the school of Alexandria, and he was one of the divinities honored by the votaries of the great Eleusinian goddesses, when the hierophant was consulted by the emperor Julian. Confounded with Sabazius, Attys, Zagreus, and Bacchus, his worship lost its distinctive and peculiar character, and was easily extinguished under Constantine and Theodosius, with the other mysteries, against which the Christian fathers waged a violent warfare as the last refuge of paganism.—See Creuzer, *Symbolik und Mythologie* (1810-'12), translated into French with elaborate annotations by Guigniaut and others (1825-'36); Lobeck, *Aglaophamus* (1830); Prelle, *Mysteria*, in Pauly's *Real-Encyclopædie* (1851); Sainte-Croix, *Recherches historiques et critiques sur les mystères du paganisme*, edited by Sylvestre de Sacy (Paris, 1817); Limbourg-Brouwer, *Histoire de la civilisation des Grecs* (Groningen, 1838-'41); Maury, *Histoire des religions de la Grèce antique* (1867); Seel, *Die Mithra Geheimnisse während der vor- und urchristlichen Zeit* (Aarau, 1823); N. MYSTERIES, mediæval dramas. See **MIRACLES AND MORALITIES**.

MYSTICISM (Gr. *μυστικός*, from *μυσ*, to shut the lips or eyes), in philosophy and theology, the doctrine that by means of an inward illumination and feeling, transcending the efforts of faith and of reason, we may immediately know, commune with, and coöperate with the Deity. It ignores the divine manifestations, whether in the signs of nature or in the ideas and processes of the soul, and claims the direct and delightful union of man with God without any intermediation whatever. It teaches that the sovereign good is the possession and enjoyment of God; that by our natural faculties we are wholly incapable of this attainment; that to confess the futility of our nature is at once the conclusion of science and the beginning of wisdom; that we inherit divine gifts only by contemplating the world, quelling the passions, escaping from the dominion of the senses, abandoning knowledge and reason, fleeing even from ourselves, transported by a preternatural inspiration, which is God in the soul. It implies the silence of sense, reason, and conscience, and the extinction of personality, in a state of mysterious inward vision and passive bliss. "No one," says Philo, "can understand this migration of the perfect soul to the eternal, not even he to whom it happens; the soul can convey no idea of the ineffable blessings which it shares, for it is wholly possessed by the spirit of God." In this state of ecstasy all disquiet, effort, and pain cease; the soul loses itself in the divine grace which fills it, and is but an instrument under the touch of Deity. The ideal of virtue and sanctity thus becomes a devout illumination, a blind abandonment of personal qualities for contemplation without thought and for prayer almost without consciousness. In some of the forms of mysticism it is by disinterested and intense love, rather than utter self-abandonment, that the divine union is accomplished. But they are universally characterized by contempt of the reason and of intellectual processes as ineffective and illusive, and by a tendency to ascetic or theurgic practices.—From the earliest periods mysticism has commonly characterized oriental religions and speculations. Pantheism, absorption into the infinite, and the extinction of self in a sort of divine trance are taught and illustrated in much of the ancient Hindoo literature, particularly in the heroic poem of the *Bhagavat-Gita*. Soofeeism is the principal mystical doctrine of Mohammedanism, and is traced by Sylvestre de Sacy to an ancient Persian sect. The mystical tendency of the East, apparent in the mysteries of the Egyptians, probably modified the Pythagorean discipline. The Orphic priesthood and some of the Greek mysteries contributed to the advancement of the doctrine, which became a prominent characteristic of Neo-Platonism, especially of the writings attributed to Iamblichus and Hermes Trismegistus. It was introduced into Christianity by the Alexandrian theo-

gians, and the books ascribed to Dionysius the Areopagite present a complete mystical system of mingled Christianity and Platonism. There are, according to him, three steps to the goal of Christian attainment: 1, purification, freeing the soul from the bonds of nature; 2, illumination, in which the disenthralled soul begins its new life; and 3, perfection, or an ecstatic existence in God, the highest manifestations of which are in prophecy and miraculous works. From him proceeded the scholastic mysticism, the most distinguished names in the development of which were St. Bernard and Hugo de St. Victor, the former treating particularly of the rapture of divine love, and the latter of the ecstasy of contemplation. The German mystics, Eckart and Tauler, gave to the doctrine a more legitimate ethical character, by dwelling upon sin instead of finiteness as the cause of evil. Some of the monastic institutions, the visions of Elizabeth of Hungary, Hildegard, Angela of Foligno, and Catharine of Sienna, and the Gnostic, Manichæan, Paulician, Bogomile, Catharist, and Beguin sects, illustrated more or less distinctly the mystical tendency. The same tendency appeared at the dawn of modern philosophy in Cornelius Agrippa, Paracelsus, Bruno, and Campanella, who sought a preternatural knowledge of the secrets and mastery over the elements of nature. The mysterious order of the Rosicrucians was believed to follow in the same direction, to possess a whole body of arcana, secretly transmitted from immemorial antiquity, and to perform divers miracles by means of elixirs and theurgical symbols. There is, however, no certain history of the Rosicrucians. The mysticism of Jacob Böhme, whom Hegel calls the first representative German philosopher, had reference to theology instead of natural science. In Spain, St. Theresa and John of the Cross were both celebrated for their raptures, and the writings of the first still hold a high place in ascetic literature. The system known as quietism came into vogue in the 17th century, being maintained in France by Mme. Guyon and in Italy by the Spanish priest Molinos; it was for a time defended by Fénelon, but the powerful opposition of Bossuet effected its ecclesiastical condemnation. A moderate and refined mysticism appears in the English Platonists Henry More, Norris, Gale, and Cudworth; and the later writings of William Law were chiefly devoted to developing the doctrines of Böhme. The romantic school in Germany caused a revival of the doctrine in literature, philosophy, and religion, its most prominent representatives in each being Novalis, Schelling, and Görres. The last defined it as "vision by means of a higher light, and action under a higher freedom," and regarded it as the highest attainment of Christian culture.—See Görres, *Die Christliche Mystik* (1836-'42); Noack, *Die Christliche Mystik* (1858); Schmidt, *Essai sur les mystiques du XIV^e siècle* (1886); and Vaughan, "Hours with the Mystics" (1886).

MYTHOLOGY (Gr. *μῦθος*, a saying, and *λογος*, science), the science of myths, of the narratives of the deeds and destinies of gods and heroes in ante-historical periods. Myths are figurative representations of events or ideas in the garb of history; they develop themselves spontaneously and unartificially in the consciousness of a primitive people, instead of being artistic products of design and invention; and they symbolize the forces and operations of nature, under whose influence they are formed, and have an essentially religious character. The myth proceeds from an idea, and creates a fact; the legend proceeds from a fact, in which it discovers an idea. The one transforms poetry, religion, or philosophy into history; the other modifies history with reference to conceptions of poetry, religion, or philosophy. Both are usually included in mythology as philosophical or poetical and historical myths. Comparative philology marks as the first period in the history of man an age in which expressions were formed for the necessary ideas of the simplest life, in which the first steps were made in the elaboration of grammar, but in which language was in the main unorganized and undivided. This was succeeded by a second period, in which at least two families of languages, the Semitic and the Aryan, advanced to a systematic grammatical development, with roots and a method which still prevail in all the dialects and national idioms founded on them. A third period intervened prior to the earliest traces of national history, which was the age of the formation of myths. There were as yet neither abstract nor collective nouns, which are fewer in number the further back we go in the history of languages; and every name, therefore, designated a definite individual object. Names moreover had a termination expressive of gender, suggestive of sex, neutrals being of later growth; and therefore while language remained in that state it was impossible to speak of whatsoever object without ascribing to it something of an individual, active, sexual, and personal character. Thus personification characterizes a stage in the formation of language corresponding to that of myths in the development of thought. All speech represented a kind of unconscious poetry, universally ascribing personal life to the forms of nature, changing all objects into powers and all relations into actions. The creation of every word was a poem, embodying a bold metaphor or a bright conception. The verbs also were expressive of personal qualities and agency, and only after passing through a long chain of vicissitudes were lifeless auxiliaries produced fitted for the purposes of abstract prose. Thus the sunset was conceived as the sun growing old, decaying, dying; the sunrise, as night giving birth to a brilliant child; spring, as the sun greeting the earth with a warm embrace, and showering treasures into the lap of nature. Rivers, fountains, grottos, forests, mountains, rain,

storm, the ocean, fire, thunder, clouds, and the heavenly bodies were all clothed with living attributes, and every description of nature was a myth. Every natural change was a sign of the hostile or peaceful, happy or ill-omened coincidence of certain divinities. Thus instituted, myths became organic elements in thought and remained as fossil poetry in language, survived national migrations and conquests and triumphed over the advance of knowledge, were modified by the contact of different peoples and by poetical and philosophical treatment, were esteemed the ultimate explanations of natural phenomena, and constituted the religious systems of the principal nations of antiquity.—The Semitic races, says Renan, have never had a mythology. From the beginning they have not varied from the conception of the government of the universe as an absolute monarchy, and have seen in the development of things only the inflexible accomplishment of the will of a Supreme Being. Endowed with a sure intuition of unity, which at once without reason or reflection unveils the Deity, they possessed the purest religious notions known in antiquity. India and Greece could not by philosophical speculation attain to monotheism, but the Semites grasped it by the instincts of their nature; and the three religions of greatest power in the history of western civilization sprang from them, from Sinai, Jerusalem, and Mecca. They could not comprehend in the divine unity variety, plurality, or sex, did not lose the idea of the infinite amid the apparent conflicts of nature, and with little interest in science may almost be said to have had a special sense for religious truth. This characteristic explains the absence of the epopee from their literature. The great poems produced by Indian, Persian, and Greek imagination were possible only in a world where the boundaries between men and gods were indeterminate, and conflict between them in some degree equal, and where revolution and progress were known in the divine dynasties.—The myths of greatest prominence and interest are those of the Indo-European nations. Before the Aryan race was broken up into nationalities, as the Indian, Greek, Roman, Slavic, Teutonic, and Celtic, it had developed the mythical germs which are now common characteristics of a whole family of mythologies, the principal of which are the Indian, the Persian, the classical, and the northern. The late mythology of the Puranas and the epic poets is more peculiarly Indian, but the elder Veda is to comparative mythology what the Sanscrit is to comparative grammar. There is in it no system of religion, there are no settled genealogies; the same god is sometimes made the superior, the equal, or the inferior of others; their first conception is in many cases transparent; and the fresh and growing personifications strikingly contrast with the fully developed and decaying myths of the poetry of Homer. The Veda gives the real theogony of

the Aryan race, of which Hesiod presents but a distorted image. The names of natural phenomena were gradually obscured, personified, and deified; but in the Veda they are *nomina* and not *numina*, masks without an actor, creations of man and not creative beings. The body of the language had not yet become petrified, and the living words which, when the relations that they expressed had faded and escaped from perception, were to be preserved as curiosities and to become organic myths, were as yet employed for the ordinary interchange of thought. The old Vedic mythology was, in general, a worship of light. The beaming æther which fills the heavenly spaces with light was the principle of life and the impulse to motion. The divinities of light were the highest; as Indra, the god of the starry firmament, of storm, thunder, and lightning; Mithra, Surya, Savitar, and other divinities of the sun; Ushas, the dawn; the two Asvins, the heralds of the dawn; and Agni, the highly honored god of fire. All the phenomena of light were regarded with reference to human life; the sun revives the earth, and calls men to prayer and sacrifice; Agni, as the mediator in the sacrificial flame, takes the gifts and prayers of men to the gods; and the lightning of Indra rends the clouds in order to shed the blessings of rain. Such were the fundamental features of Vedism before the severance of the Aryan stock. Then the ancestors of the Celts, Greeks, Italians, Germans, and Slavi migrated to Europe, and after a time other Aryan currents populated Persia and Hindostan. Each nation gave a peculiar development to the language, customs, and religion which they had possessed in common.—The following outline of the principal mythological systems mentions the more prominent religions and divinities, which are treated in detail under their titles in special articles. In the post-Vedic period first appears the Hindoo conception of Brahma as the infinite author of the universe. The pantheism of the Brahmins and the popular polytheism were developed side by side. In the age of the great epics the pantheon was already completed. From the mass of deified natural powers and elements three gods, Brahma the creator, Vishnu the preserver, and Siva the destroyer, stood forth preëminent. The most honored of the subordinate divinities are the 8 Lokapalas, who preside over and protect the 8 parts of the world. They are Indra, the god of the firmament; Agni, of fire; Yama, of the lower world; Surya, of the sun; Varuna, of water; Purana or Vayu, of the wind; Kuvera, of riches; Soma or Tshandra, of the moon. Other divinities are Kartikeya, the leader of the heavenly hosts; Ganesa, the god of wisdom; Kama, of love; Ganga, the goddess of the Ganges; Naradas, the messenger of the gods. The principal female divinities are Saraswati, wife of Brahma, protectress of the arts and sciences, especially of music; and Kali, the wife of Siva, and more than any other an ob-

ject of terror. Among demigods and fictitious heroes of poetry are the 7 or 10 Brahmadikas or Rishis (seers), the greatest of whom is Dakshas, the father of the Asuras (demons) by Diti, and of the Devas (divine persons) by Aditi. The Gandharias are the heavenly singers and dancers; the Apsarasas, heavenly nymphs; the Yakshas, attendants of Kuera, and guardians of treasures in mountains; and the Rakshasas, hostile to men and to everything good. Other evil spirits are the Kinnaras and the Pisatschas. The three worlds, divine, human, and infernal, which now exist, are not to be eternal, but will be terminated by Kali. Of animals, the bull, serpents, and the bird Garuda which accompanies the gods, are particularly worshipped. The banian or Indian fig tree is deemed sacred. Buddhism and Lamaism preserved with modifications most of the old Brahminic divinities. No other mythology is so comprehensive and complicated as that of the Indians, the doctrines of which concerning cosmogony, theogony, and human life and destiny are alike marked by a mystical ideality. It has been claimed that there is no idea nor fable holding a distinguished place in western systems of religion, the counterpart of which does not exist in the Indian.—In Mazdeism, the religion of the ancient Persians, supposed to have been revealed by Zoroaster, and still professed by the Parsees, Ormuzd is the highest divinity, and reigns in heaven. He has at his command a hierarchy of spirits, foremost among whom are the 6 Amshaspands, representatives respectively of goodness, truth, justice, piety, riches, and immortality. The second class are the 28 Izeds, who rule the elements, the first of whom is Mithra or the sun. The universe, created out of light and water, had scarcely proceeded from the hands of Ormuzd, when the genius of opposition and evil appeared in Ahriman, of nearly equal power, whose origin is veiled in obscurity. He created the archdevs and the devs to resist the Amshaspands and the Izeds. The Ferners are only the ideas of the Supreme Being embodied, and as a whole they constitute the essential idea of the world, of which the visible creation is but an imperfect imitation. Every object and being, the stars, animals, men, and divinities, have their Ferner or type, by which they exist. Among fabulous beasts are the beneficent bull Saresek, the Ahrimanic monster Martichoras, the sacred birds Hufrashmodad and Corosh, and the bull Abudad, from the blood of which sprang the animal and the vegetable worlds. The fundamental idea of Mazdeism is the struggle with evil, the final defeat and extinction of which is predicted. To Persia has been attributed much of the fairy and heroic mythology of European mediæval romance.—“The mythical world of the Greeks,” says Grote, “opens with the gods, anterior as well as superior to man; it gradually descends, first to heroes, and next to the human race.” It is rivalled only by that of the Indians in multi-

farious wealth, and by none in the beauty of its forms. It represents the world as originally a rude and chaotic mass, from which Heaven (Uranus) and Earth (Gæa) separated themselves as independent divinities. The first race of gods were the Uranida, sons of Heaven and Earth. The powerful brood of the Titans belonged to them. Cronos ruled the second race, but was overthrown by Zeus, who firmly secured his throne after wars with the Titans and Giants in which all nature was convulsed. From the age of the Homeric poems he was regarded as the head of the entire system, the god of heaven and light, holding his seat upon Olympus, in the pure expanse of æther. He divided his dominions with Poseidon and Pluto, yielding to the former the realm of the sea, and to the latter that of the under world, the dwelling place of the shades of the dead. His throne was surrounded by 11 other great Olympian gods and goddesses: Poseidon, Apollo, Ares, Hephaestus, Hermes, Hera, Athena, Artemis, Aphrodite, Hestia, and Demeter. There was an indefinite number of other divinities, some of them of nearly equal power, as Pluto, Helios, Hecate, Dionysus, Lato, Dione, Persephone, Selene, Themis, Eos, Æolus, Nemesis, the Graces, the Muses, the Fates (Moiræ), the Eumenides, the Oceanids, the Nereids, the Nymphs, and the Hours. There were other deities whose personality was more faintly conceived, as Ate, the Litæ, Eris, Thanatos, Hypnos, Cratos, and Bia. There were also monsters, the offspring of the gods, as the Harpies, Gorgons, Grææ, Pegasus, Chrysaor, Echidna, Chimæra, Cerberus, Geryon, the Lernaean hydra, the Nemean lion, the centaur, the sirens, the sphinx, Scylla and Charybdis. These divinities peopled the earth, the heavens, the sea, and the infernal world. Poseidon was surrounded by Amphitrite, Thetis, the Nereids, and the Tritons; the Eumenides pursued guilt and remorse; Persephone reigned with Pluto in Hades, the entrance to which was guarded by Cerberus; Minos, Æacus, and Rhadamanthus judged the shades of the dead; Pan and the Fauns ruled in fields; the Nymphs, in mountains and fountains; the Dryads and Hamadryads in forests; the Muses and the Graces inspired poetry and beauty; Eos opened to Apollo the gates of the sky; Æolus bound the winds in caves, or sent them forth on their mission; and the rainbow was the highway of Iris, the messenger of the gods. Above the whole system Destiny was vaguely conceived as a resistless power, which, however, rarely interferes to violate the freedom of the world. Elaborated by poets and philosophers, the Greek mythology attained a nearly symmetrical development, and embodied an aggregate of religious, physical, and historical doctrines, which formed the whole staple of Greek culture. It included elements borrowed more or less directly from the Orient, and modified by the Greek genius, but many of its historical dependencies are still matters of investigation and

discussion. It remained the most important and the characteristic ingredient in the religion of ancient Rome. The Romans, in adopting the Greek mythology, for the most part mingled with it the legends and transferred to it the names of their own divinities, or imparted to the Greek names a Latinized form; and it is by these Latin names that both the Greek and Roman divinities have been most generally known in later times. Thus, Cronos they called Saturnus; Zeus, Jupiter; Poseidon, Neptuneus; Ares, Mars; Hephæstus, Vulcanus; Hermes, Mercurius; Hera, Juno; Athena, Minerva; Artemis, Diana; Aphrodite, Venus; Hestia, Vesta; Demeter, Ceres; Dionysus, Bacchus; Leto, Latona; Persephone, Proserpina; Selene, Luna; the Mœræ, Parcs, &c.—The northern mythology was originally monotheistic, Alfdur, the father of all, receiving the loftiest names as the Supreme Being. But in the popular faith Odin was worshipped as the chief of the Asen, the 12 most powerful gods and goddesses. In the beginning there was neither shore, nor sea, nor earth, but only one vast abyss. To the north of this was Nifheim, a world of icy coldness and full of gloom, with the fountain Hvergelmir in its midst; to the south was Muspelheim, a hot and luminous world, habitable only by the sons of fire. From Hvergelmir flowed forth ice-cold venom streams, the rime of which once met with sparks from Muspelheim, and the consequence was that the Jotun Ymer came into being, the father of the race of evil Jotuns called frost giants. With Ymer sprang to life also the wonderful cow Andhumla, which by licking the salt stones called forth Buri, a beautiful and mighty being, the second generation from whom was Odin, the father of the Asen, the ruling gods of heaven and earth. With his two brothers he overthrew the Jotuns, and destroyed all but one pair. They made of the eyebrows of Ymer the citadel of Midgard (middle earth), destined to become the abode of the human race, which they created, the male from an ash tree, and the female from an alder. The sea forms a belt around the earth, beyond which is the land of giants. The ash tree Yggdrasil supports the whole universe. At its root is a sacred fountain, by which sit the three great Norns or Destinies. Asgard is the abode of the gods, consisting of golden and silver palaces, the most splendid of which is Valhalla, the residence of Odin, where he receives and welcomes the spirits of heroes slain in battle. The greatest of the Asen are Odin, Frigga, Thor, Njord, Freyr, Freyja, Baldur, Loki, Heimdall, Tyr, Hodur, Vali, and Vidarr. Other mythological beings are the giants, norns, elves, dwarfs, the wolf Fenris, the serpent Jormungandr, the water spirits, the Valkyrior, the Strömkarl of Sweden, and the Högspe-lars, whose silver harps are heard in the cascades and torrents. The author of the greatest misfortunes which have befallen gods and men is Loki, who contrived the death of Baldur, which

was wrought by the hands of Hodur, and thus exposed the whole Asen dynasty to ruin. The death of Baldur prefigures the overthrow of the Asen divinities, and of the present cosmological system, which catastrophe will be followed by a new world and new gods. The whole mythology breathes the spirit of war. The myths consist chiefly of the exploits of the gods, and heroic men who have given the most illustrious examples of the Berserkir rage are received into Valhalla only to engage in supreme felicity in mimic combats and hunting matches. The old German and the Slavic mythologies are akin to the Scandinavian. The legends of the ancient Egyptians, Chaldeans, Phœnicians, and Celts, of the American Indians, Mexicans, and Peruvians, and of most barbarous nations, constitute mythologies.—After the revival of letters Boccaccio and others reproduced the myths of classical antiquity, employing them to aid literary taste and invention. The allegorical method of interpretation succeeded, and Bacon discovered in them concealed germs of moral and social doctrine, and Vico deduced from them the primitive conceptions of reason, the first fruits of imagination, the beginnings of social order. G. J. Vossius and Spanheim sought to explain them as offshoots and counterfeits of the biblical revelation. Bainer applied the Euhemeristic method to them, and Fréret treated them as positive external enactments. In Germany the hypothesis of an original monotheistic religion, from which mythologies had degenerated, long prevailed. India and Egypt, the populace and the priestly caste, were by different authors (Plessing, Kanne, Görres, Faber) supposed to have possessed this primitive superior knowledge. Others believed them to have a definite scientific import, as to astronomy (Dupuis, Court de Gébélis, Dornedden) or chemistry (Toll, Schweigger). Heyne, who first brought extensive and minute scholarship to bear on the subject, stated the foundation of myths to be either events or notions of earlier humanity; they are therefore either historical or philosophical. The *sermo symbolicus et mythicus* arose necessarily in the infancy of the race; the mind, accustomed only to sensual impressions, sought for external images, and transformed its ideas into narratives of external events. The expression became gradually identified with a new fact, lost its original meaning, and the priests fostered the error. The oldest myths are the physical, and the next the theogonic. For a long time the poets only embellished and altered them, but afterward made use of them as artistic materials, and added to them grace and elegance. They were subsequently modified also by philosophers, so that their authentic interpretation is not now to be expected. According to Voas, the first conception of mankind was that every thing had sprung from earth, water, and air, and these from the separation of a shapeless, confused mass of rude primary materials. This is the origin of popular myths. But

teachers of wisdom, priestly or secular, introduced a more rational meaning into these ancestral forms of adoration. Echoes of the Mosaic doctrine of creation, of the deluge, of the glory of the Deity, were also interwoven, and different faiths were intermingled. The pure Hellenic worship was chiefly corrupted by a secret sect of Orphici, who engrafted on it a medley of Phrygian, Egyptian, and Persian notions, and who aimed only to exalt a priesthood. Buttmann considered the actions and events of the mythic world as the accidental offspring of a rich and variously endowed imagination going forth in search of the marvellous. They arose in various places, partly in Greece, partly in the East, were subsequently formed into groups, transferred into various cycles, combined and harmonized, until they retained nothing historical except incidental indications concerning ethnography and geography. The events from which they resulted cannot be evolved with certainty. This is in substance the opinion also of Grote. Creuzer attributes the mythology of the Greeks to the benevolent design of priests educated in the East to raise the people to a purer and higher knowledge. These instructors adapted their lessons by veiling them in figures. To form symbols and to interpret symbols were the main occupations of the ancient priesthood. The most lively personification was a fundamental law. A mass of symbolical and allegorical inventions, derived from the East, lie at the bottom of the Greek mythology, and grew up in connection with the native heroic legends. Their original character, however, was that of a pure monotheistic primitive religion. Hermann defined a myth as a figurative representation of an idea. Mythology is the science of the fundamental ideas of a people, and must be explained on the supposition of a connected system of public knowledge, quite distinct from the popular belief. Welcker maintained that at the basis of Greek mythology lies a hierarchical system of nature, a series of contemplations and speculations, which was preserved in an ancient priestly phraseology, till it was broken and scattered through the whole of mythology. This system is still preserved, particularly in the names, many of which cannot, however, be explained from the Greek language, since they belong to a time when the distinct individual nation was not yet formed. He thus suggested and gave an impulse to the study of comparative mythology, which has been prosecuted by K. O. Müller, Max Müller, and others, and which introduces universal comparative exegesis in place of the separate study of any people. Gladstone reverts to the older theory of derivation from an original revelation. The Homeric poems, according to him, contain the vestiges of a real traditional knowledge, inherited from the epoch when the covenant of God with man and the promise of a Messiah had not yet fallen within the contracted forms of Judaism for

shelter, but entered more or less into the common consciousness, and formed a part of the patrimony of the human race. With a basis of ancient theistic and Messianic predictions, derived from the dispersed kin and contemporaries of the patriarchs, and modified as they travelled further and further from their source, there were added abundant elements of merely human fabrication. The leading scriptural traditions are represented by imperfect and deranged counterparts in the heroic age of Greece. Thus the unity and the supremacy of the Godhead appear in Jupiter, the administrator of sovereign power. The combination of trinity with unity is represented in the 3 Cronid brothers, Jupiter, Neptune, and Pluto, to whom are assigned different regions of the material creation. The tradition of the Redeemer is supposed to have undergone disintegration. The various attributes which were conceived as belonging to him could not be held in combination by the Greek mind. Its first form as deliverer is represented by Apollo, some of the attributes being transferred to his sister Diana or repeated in her. The second form is the Homeric Minerva, corresponding to the Logos of St. John. Latona, the mother of Apollo and Diana, is regarded as representative of the tradition of the woman from whom the deliverer was to descend. The notion of the Evil One, also, shows the process of disintegration, followed by that of an arbitrary reassertment and combination of elements. The idea of a rebellion, menacing the divine dominion with violence, is clothed with a variety of detached and more or less conflicting forms; and the more subtle idea of an influence acting immediately on the spirit of man, and aiming a blow at the glory of the Deity through his creatures, whose allegiance it seeks by the perversion of their own spontaneous agency to withdraw, remains in Homer, but so obscured and enfeebled as to be scarcely recognized. The idea of Evil acting by violence is represented, not exclusively but most conspicuously, in the Titans and Giants. The idea of Evil acting by deceit is represented in Ate. The rainbow of Scripture is represented in the Homeric Iris.—See Creuzer, *Symbolik und Mythologie der alten Völker* (4 vols., 8d ed., 1836-'48); K. O. Müller, *Prolegomena zu einer wissenschaftlichen Mythologie* (1825); Eckermann, *Lehrbuch der Religionsgeschichte und Mythologie der verschiedenen Völker des Alterthums* (1845-'7); Wuttke, *Geschichte des Heidenthums* (2d ed., Berlin, 1855); *Griechische Mythologie*, by Gerhard (1854), Preller (1854-'5), and Welcker (1857); Grimm, *Deutsche Mythologie* (1885); Mallet, "Northern Antiquities" (new ed., London, 1847); Keyser, "The Religion of the Northmen," translated by Pennock (New York, 1854); and Max Müller, an essay on comparative mythology in the "Oxford Essays" for 1856.

MYXINOIDS, an order of fishes, which, with the cyclostomes or lampreys, form the class

of myzonts of Agassiz, containing the lowest of the vertebrates. They form the family *Hyperotreta* (Müll.), and are characterized by a cylindrical body, obliquely truncated anteriorly; the mouth is furnished with cirri or tentacles, the palate is perforated, and the cavities of the nose and mouth communicate (as in no other fish); the upper margin of the mouth has a single tooth, and the tongue has a double recurved row on each side; the under jaw is absent, and the inferior margin of the mouth is formed by the anterior extremity of the tongue bone; the eyes are concealed; the branchiæ are on each side with internal ducts leading to the oesophagus. For full details see the papers of J. Müller, in the "Transactions of the Berlin Academy" for 1834, 1838, 1839, and 1842. In the genus *myzine* (Linn.) 2 spiracles approximate on the lower surface behind the branchiæ, each receiving the external ducts of the 6 branchiæ of its own side. The common myxine or glutinous hag (*M. glutinosa*, Linn.) has a smooth eel-like body, with a very long dorsal fin continued round the tail to the vent, a single spiracle on the head, and 8 barbules around the mouth; the color is bluish brown above and whitish below; the length is from 6 to 15 inches. Linnæus placed this animal

among worms, regarding the 2 lateral parts of the tongue as transverse jaws, which do not occur in vertebrates. The specific name is derived from the great quantity of viscid mucus secreted by the cutaneous glands whose pores open along the under surface of the body; the spinal column is a soft and flexible cartilaginous tube, with no division into rudimentary vertebrae. It is called borer from its habit of eating into the bodies of other fish which have been caught on hooks, entering the mouth or other part of the surface, and in this way is often annoying to fishermen during spring and summer. It is found along the coast of Great Britain and in the northern seas. In the genus *heptatrema* (Dum.) or *bdellostoma* (Müll.) there are 6 or 7 branchiæ on each side, each with an external spiracle; the eyes are very small, conspicuous through the skin. It resembles the preceding genus in internal structure, and attains a larger size; it is found in the southern seas, preferring rocky bottoms, where it lies in wait for fishes; it is active, and has remarkable powers of emitting mucus from the skin. The only species described (*B. Forsteri*, Müll.) is one that is roasted and eaten by the New Zealanders.

MYZONTS. See MYXINIDS.

N

N the 14th letter and the 11th consonant of the English alphabet. N (*Nun*) was placed immediately after *m* (*Mem*) in the ancient alphabets, either from the affinity of their sounds, or from the association of ideas in their names, *Mem* in Semitic signifying water, and *Nun* a fish. The usual sound of the English N, or that which it naturally has when not affected, by the neighboring consonants, is that of a lingual nasal. This is in the English language an original sound, derived without change from the earlier languages. There is, however, an exception in *phenomenon* and similar words, where the final *n*, in the singular neuter, represents an earlier *m*. There is an epenthetic *n* in *bring* (comp. *brought*), *think* (comp. *thought*); also in some words of Latin origin, as *frangible* (comp. *fracture*), *tangent* (comp. *tact*). The letter *n* final, after *l* or *m*, is silent in English, as *condemn*, *kiln*, *column*, *hymn*; but this *n* was originally sounded. The omission of an *n* is sometimes indicated merely by the lengthening of the preceding vowel, as *goose* (Germ. *Gans*), *tooth* (Lat. *dens*, genit. *dentis*; Mæso-Gothic, *tunthus*), *tithe* (comp. *tenth*). The English *n*, when it comes immediately before a palatal mute, as *c*, *ch* (when pronounced like *k*), *g*, *k*, *q*, or *x*, is a palatal nasal, or has the sound of *ng* final. Dr. Worcester, in his quarto dictionary, has made a careful collection of 78 words in which *n* has this palatal sound. In *ng* final, the palatal sound has arisen in the

same way, although the sound of *g* has been dropped in English. But the suffix *ing* appears to have arisen from the infinitive termination *on* in the earlier language. The Anglo-Saxon and Latin have the same two nasal sounds of *n* as the English. The Mæso-Gothic and the Greek have the two nasal sounds, but express the palatal nasal by *g*. The Latin of the earliest authors had sometimes *g* and sometimes *n* for the palatal nasal. (See W. Corssen, *Ueber Aussprache der Lateinischen Sprache*, vol. i. pp. 104, 105, Leipzig, 1858.) The Sanscrit language has a great variety of *n* sounds.—In numeration, the Greek N signified 50. Among the Romans, according to some authors, N signified 90; according to others 900, and with a horizontal line above it, 90,000.

NABIS, a Spartan tyrant who raised himself to supreme power on the death of Machanidas in 207 B. C. He caused the young son of the deceased king Lycurgus to be assassinated; the most influential citizens were put to death or banished; the wealthy were subjected to incessant exactions enforced by torture, and one of the tyrant's favorite engines of punishment was the figure of a woman which he called his wife Apega, and which being made to embrace the victim pierced him with spikes projecting from its breast and arms. The money obtained by such oppressive means enabled him to support a mercenary force to crush the spirit of Sparta, attempt the restoration of

the Lacedæmonian ascendancy in the Peloponnesus, and seize the city of Messene, though he was then actually in alliance with her. He was forced however to withdraw by the Megalopolitan general Philopœmen, but in the next year he returned and reduced the territory of Megalopolis to great distress. On the conclusion of the first Macedonian war, Flamininus, the Roman consul, submitted the question of peace or war with Nabis to a congress of the Grecian allies of Rome held at Corinth in 195 B. C.; and war having been unanimously decreed against him, Flamininus, with a powerful force, invaded Laconia, and laid siege to Sparta. The tyrant made an obstinate defence, but was ultimately constrained to purchase peace by subscribing to the most abject conditions. In 192, having again involved himself in hostilities with the Achæans, once more under the lead of Philopœmen, he applied to the Ætolians for succor. They sent a small force, ostensibly to assist but in reality to overthrow him, and he was soon assassinated by their general Alexamenus.

NABLOOS, or **NABULUS**, a town of Syria, capital of a circle of its own name in the pashalic of Damascus, 80 m. N. from Jerusalem, in lat. 32° 12' N., long. 35° 28' E.; pop. estimated at 8,000. It is situated in a valley at the base of Mt. Gerizim, and is supposed to occupy the site of the ancient Shechem. When restored by the Romans in the reign of Vespasian, it received the name of Neapolis, of which its modern name is a corruption.

NABOB (Hind. *nawab*), a title of office in India, applied during the Mogul empire to the imperial lieutenant or viceroy of a province. The word is the plural of *naiib*, prince, it being a custom of the natives to address all great men in the plural number. The imperial commission conferred upon a nabob the power of bestowing titles below the rank of *omrah* (lord); he was permitted to grant estates subject to confirmation by the supreme authority; he leased the lands to the general farmers, but had no part in the collection of the revenue, except, in case of necessity, assisting the imperial officers with the military force. He had power, for disobedience or crime, to suspend the *omrahs* from pay till the case was examined at court. In matters of justice there rested an appeal to his tribunal from the *cazi*, or chief justice, though he seldom reversed the decrees of that judge. Disputes where property was not concerned, and where the established laws made no provision, were settled by his authority; but he was forbidden to eject the subjects of the empire from their lands or houses. As the power of the emperors declined, their deputies became independent. They made war upon each other, and the country was perpetually disturbed by their contentions. The English, availing themselves of these dissensions, reduced them in detail to mere pensioners on their bounty.—In the English language the word nabob was introduced when the early

adventurers returned to Great Britain from Hindostan, and signifies a man who has acquired great wealth in the East.

NACOGDOCHES, an E. co. of Texas, bounded S. W. by the Angelina river and E. by the Attoyac, which unite at the S. E. corner; area, 886 sq. m.; pop. in 1858, 7,091, of whom 1,694 were slaves. It has an undulating surface, occasionally hilly and broken, and generally well timbered. The soil varies greatly, but is mostly fertile, cotton and corn being the principal crops. The productions in 1850 were 139,110 bushels of Indian corn, 8,849 of oats, 88,260 of sweet potatoes, 1,109 lbs. of tobacco, 43,845 of butter, and 835 bales of cotton. There were 16 churches, and 240 pupils attending public schools. Capital, Nacogdoches.

NADESHDIN, **NICOLAI IVANOWITCH**, a Russian author, born in Nijni Bieloomut, Riazan, Oct. 17, 1804, died in St. Petersburg, Jan. 23, 1856. He was the son of a clergyman, and was graduated in 1824 as a doctor of theology at the academy of Moscow. He filled for two years the chair of Russian and Latin literature at the seminary of Riazan, and afterward devoted himself in Moscow exclusively to literary pursuits, chiefly as a journalist. He was appointed professor of archaeology at the university of Moscow, travelled in Germany, France, and the Crimea, and embodied the results of his archaeological investigations in the memoirs of the Odessa historical and archaeological society. In 1836 he left his professorship and the "Telescope" journal in Moscow, and resided successively at Vologda and Odessa. He published a description of his observations in that region in his "Russian Alhambra" (1839), and "Journey through Bessarabia" (1840). In 1840-'41 he explored S. E. Europe under the auspices of the Odessa society, and on his return spent some time in Vienna, where he published an essay on Russian dialects in the *Jahrbücher der Literatur*. In 1842 he was appointed by Pelovsky, the Russian minister of the interior, to conduct the journal published in St. Petersburg under his auspices; and in 1846 he became one of the founders of the geographical society in that city, in which he was made president of the ethnological department. Among his last productions was a Russian translation in 10 volumes of Ritter's *Erdrkunde*. He wrote largely for the Russian cyclopædia, and for Senkovsky's "Library."

NADIR, in astronomy, that point of the lower celestial hemisphere directly under our feet, and opposite the zenith. It and the zenith constitute the two poles of the horizon.

NADIR SHAH, or **KOULI KHAN**, a king of Persia, born in the village of Abuver, near Kelat in Khorassan, Nov. 11, 1688, assassinated June 19 or 20, 1747. His father, who belonged to the Toorkish tribe of Affahar, and was a maker of sheepskin caps and coats, died when his son was scarcely 13 years old. At the age of 17 Nadir was taken prisoner in an

invasion of Khorassan by the Usbecks, but after remaining in captivity 4 years, escaped and entered the service of the governor of Khorassan, where he attained to high rank. But having been degraded and severely punished by his master, he fled, and, placing himself at the head of a band of robbers, soon became feared for his daring exploits. The civil commotions of the times opened a field for his ambition. The leaders of the Afghan army, which had overrun Persia in the beginning of the 18th century, had dethroned the monarch of the Safian line; but, hated for their cruelty and oppression, their power in the remoter provinces was weak, and Tamasp, the son of the last king, was enabled to maintain a precarious independence. Nadir Shah joined him at Mazanderan in 1727, at the head of 5,000 men, with the declared intention of expelling every Afghan from the soil of Persia. Raised to the supreme command, he took Meshed and Herat, defeated the Afghan king, Ashrif, in a series of bloody engagements, drove him out of the province of Khorassan, pursued the flying army to Ispahan, and finally overtook it at Persepolis. Eventually Ashrif was slain, and his forces were almost entirely cut to pieces. For his services Nadir received from Tamasp in 1730 the four provinces of Khorassan, Mazanderan, Seistan, and Kerman, and assumed the title of Tamasp-Kouli (Tamasp's slave), to which Khan was added by his sovereign. War with the Turks breaking out in 1731, Nadir defeated them on the plains of Hamadan; but returning to quell an insurrection of the Afghans, the imbecile Tamasp took the opportunity of marching against the Turks, and being ingloriously vanquished, signed a treaty of peace in which he ceded to them several provinces. The discontent excited by this treaty was fanned by Nadir, who published a proclamation declaring his intention to carry on the war, and finally dethroned his sovereign, Aug. 16, 1732, and afterward secretly caused him to be put to death. The son of Tamasp, Abbas III., an infant 8 months old, was made the nominal ruler, but died in 1736. An assembly was called to consider the state of the kingdom, at which, it is said, more than 100,000 persons were present; and here Nadir Shah with much apparent reluctance accepted the crown, Feb. 26, 1736. In the mean time he had wrested from the Turks the ceded provinces, and, having concluded a peace, turned his victorious arms upon the Afghans. The province of Candahar was invaded, the city of that name taken in 1738, and his son, Riza Kouli, subsequently crossed the Jihoon or Oxus, and overthrew the ruler of Bokhara and the Usbecks. Afghanistan was soon afterward conquered, and some fugitives having taken refuge in Hindostan, Nadir sent an ambassador to demand them, who with all his suite was murdered by the populace at Jelalabad. The Mogul emperor having refused satisfaction for the outrage, Nadir marched into Hindostan the following

year, defeated the Mogul army, and entered Delhi, which at first he treated with singular moderation; but the inhabitants having suddenly risen upon the Persians and killed a considerable number, Nadir ordered a general massacre of the Hindoos in every house in which a murdered Persian was found. The slaughter lasted from morning till noon, and was then suspended by Nadir's orders. The immense treasures, which the Mogul emperors had spent two centuries in amassing, were seized to the amount of \$100,000,000, including the Koh-i-noor diamond, and with his plunder Nadir returned to Persia without depriving the Mogul emperor of any provinces except those west of the Indus. In 1740 he forced the sovereign of Bokhara to submit to his power, and then marched against the king of Kharezm, whom he defeated in battle, took prisoner, and put to death. His dominions were extended from the Indus on the east almost to the plains of Bagdad on the west, and from the Persian gulf on the south to the Oxus on the north, thus reviving the ancient glory of the Persian empire. Hitherto he had ruled with moderation, but the latter years of his life were stained by the foulest acts of cruelty. In an expedition against the Leaghis he was wounded by a shot fired at him from a wood; and having been led to believe that it was the work of his son, Riza Kouli, he ordered his eyes to be put out. But, struck with remorse at the act, and filled with fury at his courtiers for not having prevented it, he put to death 50 of them. Subsequently not only individuals, but whole cities, were put to the sword on the slightest suspicion. Liberal in the first part of his reign, he became avaricious as he grew old, and the whole empire groaned under his exactions. At length a number of noblemen, hearing that they were included in a proscribed list, resolved to assassinate the tyrant; and 4 of them, employed about the court, made their way into his tent in the night, and despatched him. In spite of his excesses, his countrymen continue to look upon him with pride and gratitude, as having restored Persia to her independence as a nation. His life was written in Persian by Mirza Mohammed Mahadi Khan, his secretary, and has been translated into French by Sir W. Jones. A detailed account of his career is given by Malcolm in the 2d volume of the "History of Persia," and by Fraser, whose authorities were Persian MSS. (London, 1742).

NÆVIUS, CNEIUS, a Roman poet and dramatist, born probably in Campania between 274 and 264 B. C., died in Utica, Africa, about 204 or 202 B. C. He served in the first Punic war, settled in Rome, and produced his earliest play in 235, making the stage a vehicle for assailing the aristocracy. For a libel on Q. Cæcilius Metellus, one of the proudest of the patricians, he was cast into prison, and obtained his release by two plays, the *Horatius* and *Leon*, in which he recanted his calumnies.

Having again offended, he went into exile at Utica, and employed his latter days upon his great epic poem on the "Punic War," a few fragments of which are still extant. Though written in the old Saturnian metre, it was highly appreciated even in the Augustan age, Virgil having adopted several passages from it. The best edition of his few extant fragments is that of Olusmann (Jena, 1848).

NAGASAKI (pronounced *Nangasaki*), a city and port of Japan, on the S. W. side of the island of Kiusiu, in lat. $32^{\circ}44'8''$ N., and long. $129^{\circ}51'58''$ E., 800 m. from Yeddo; pop. about 60,000. The bay of Nagasaki is 7 m. in length by 1 in breadth, and is bounded by high and steep hills on which are numerous batteries of cannon. There are also several fortified islands in the bay, the highest of which is the Papenberg, so called by the Dutch from the fact that, during the persecution of the Christians in Japan, the Catholic priests were thrown from its summit. The harbor comprises 3 safe anchorages: the outer one, west of Papenberg; the second in the middle, E. of that island; and the third at the bottom of the harbor, in front of the city. In all these roads there is sufficient water for the largest vessels. The scenery around Nagasaki is very beautiful, resembling the best parts of the S. coast of England, though on a much grander scale. The city lies along the water's edge, and spreads upward between and among the hills, which are here from 1,000 to 1,800 feet high. The greater part of the houses lie in an ascending valley between two hills, spreading on either hand some distance up the hillsides. The length of the city is about $\frac{1}{4}$ of a mile, with nearly the same breadth. Three large streams flow from the hills into the harbor, the largest being crossed by more than 20 substantial stone bridges of one and two arches. The hills are so steep that the houses are ranged in tiers one above the other like the seats of a theatre, the floor of one house being on a level with the roof of its next lower neighbor. At frequent intervals flights of stone steps lead upward to temples hidden among shrubbery and trees, and sometimes to tea houses or houses of entertainment and pleasure. Many of the streets are long, handsome avenues, 30 or 40 feet wide, with a smooth, well beaten, and cleanly swept roadway, having a narrow stone pavement in the centre. The houses are mostly neat wooden cottages, each surrounded by a court or garden. The situation of the city is convenient for drainage, and rills of water from the hills flow through all the principal streets. On the 3 large streams there are a few grist mills of rude construction; and on the opposite side of the bay from the city there is a steam foundry managed wholly by native workmen who have been instructed by the Dutch. There are about 50 European and American residents at Nagasaki, which has been open to foreign commerce since July 1, 1859. It is one of the 5 imperial cities of Japan, and is the residence of a gov-

ernor, who is changed at the end of 3 years. There is a Chinese factory called To-Zin-Jasiki, which forms the southern suburb of the city. Ten vessels are annually allowed to enter the port from China. The internal commerce is extensive, and there are manufactures of porcelain and silk goods.—Nagasaki, about the middle of the 16th century, was a small fishing village, when the prince of Omura, being converted to Christianity, allowed some Portuguese merchants to settle there, and in 1568 built a church and invited the Portuguese missionaries to make it their head-quarters, promising them that no religion but Christianity should be tolerated there. Converts flocked thither, and Nagasaki soon became a considerable city. Shortly afterward, however, the persecution of the Christians began, and in 1621 all the churches were destroyed, and heathen temples built on their sites. By an imperial edict in 1624 all the ports in Japan were closed to foreigners except Firando, where the Dutch and English were allowed to trade, and Nagasaki, which remained open to the Portuguese and Chinese. In 1685 the Portuguese were confined to an artificial island called Desima, formed by throwing rubbish into a shallow part of the harbor, and connected with the shore by a small stone bridge. This island, in shape like a fan, is 236 paces in length and 82 in breadth, and about 4 feet above the water. Its area is 3 acres. In 1688 the Portuguese were wholly banished from Japan, and 8 years later the Dutch merchants were ordered to remove from Firando and establish themselves in Desima, to which for more than two centuries they were closely confined, till the recent opening of Nagasaki to foreign commerce. Their number was limited to 11 men, no foreign women being admitted, and only two ships were allowed to come annually from Batavia with cargoes of sugar, tin, spices, woollens, chintzes, and some small miscellaneous articles, to the amount in all of about \$300,000. Desima is still occupied by Dutch merchants, but they are no longer guarded and restricted as formerly.

NAGPOOR, or NAGPORE, a province of British India, in the Bengal presidency, situated between lat $17^{\circ}50'$ and $23^{\circ}5'$ N., and long. $78^{\circ}8'$ and $83^{\circ}10'$ E.; area, 76,500 sq. m.; pop. 4,650,000. It is divided into 5 districts; the principal towns, beside the capital, are Chanda, Ryepoor, Bundara, and Kamptee. The surface is in general elevated, with a slope toward the bay of Bengal. The S. E. part of the territory, comprising about $\frac{1}{4}$ of the whole, has not been explored by Europeans. It is woody and hilly; the valleys are partially cleared and planted. The rajahs of Nagpoor, sometimes called of Berar, were the rulers of a state which formed a branch of the great Mahratta confederation; but at the death of the last of the dynasty in 1853, the territory was annexed to the British empire. (See BERAR.)—NAGPOOR, the capital, is 440 m. N. E. from Bom-

bay; pop. 111,231. It is 7 m. in circumference, but very straggling; and most of the houses are of mud, roofed with either thatch or tiles. Silk, cotton, and cutlery are manufactured. Nagpoor was an insignificant village in 1740, when the Bhoonlah rajah made it the seat of an independent Mahratta sovereignty.

NAGY-SÁNDOR, József, a Hungarian general, born in Grosswardein in 1804, executed in Arad, Oct. 6, 1849. He early entered the Austrian army, but was living on half pay as a lieutenant of cavalry when the revolution of 1848 broke out. He commanded the cavalry of the Hungarian national guard, distinguished himself in the south of Hungary, especially on Oct. 15, 1848, was active under Görgey in the campaign in the early part of 1849, was promoted to the rank of general, April 6, and was conspicuous for his courage at the siege of Buda. He subsequently commanded on the upper Danube and the Waag. He was a declared friend of republican institutions, and the first to suspect the proceedings of Görgey. He accompanied the latter on his retreat from Comorn in July, on which occasion he and his soldiers were subjected to great sufferings, his corps being greatly cut up at the battle of Waitzen, July 15 and 16, and two days afterward near Felső-Szűgy. The army having crossed the Theiss, Nagy-Sándor's division was surprised before Debreczin by an overwhelming force of Russians under Paskevitch, and dispersed after a gallant though short struggle (Aug. 2). He fought once more on the Maros, near Arad. A few days later Görgey's surrender at Világos (Aug. 13) made him a captive in the hands of the Russians, and with his comrades he was surrendered to the Austrians. They were sentenced to death by a court martial, and executed at Arad. He met his fate with heroic calmness. His last words are said to have been: *Hódie mihi, cras tibi.*

NAHANT, a post village, township, and watering place of Essex co., Mass., 10 m. N. E. from Boston by water; pop. in 1855, 270. The township was separated from Lynn in 1853. It is a peninsula, running out about 3½ m. into Massachusetts bay, and consists of two islands connected by a beach ¼ m. in length, and united to Lynn by another beach 2 m. in length. The original Indian name of the place, Nahanteu, signifies twins or two things united. The larger of the two islands, called Great Nahant, is 2 m. long and ¼ m. broad, and contains 463 acres. At the E. extremity is a large hotel, and numerous cottages are scattered over it, used chiefly as summer residences by the citizens of Boston. In many places the shore is lined by rocks rising 20 to 60 feet above the tide; and there are many singular caves and fissures, the most noted of which are the Swallow's cave and the Spouting Horn. Little Nahant, which lies between Great Nahant and the mainland, rises 80 feet above the sea, and comprises about 40 acres. The isthmus which connects it with Lynn is a narrow beach of

sand and gravel so hard that a horse's footsteps scarcely leave a trace. Nahant has long been a favorite watering place during the summer months. E. of Nahant at the distance of a mile is Egg Rock, rising abruptly to the height of 86 feet, and crowned by a lighthouse.

NAHUM (Heb., "consolation"), the 7th of the lesser prophets in order of arrangement of the Greek and Hebrew Scriptures, but the 6th in order of time, born in Elkosh, a village of Galilee, flourished about the beginning of the 7th century B. C. He prophesied in Judah toward the close of the reign of Hezekiah, after the deportation of the 10 tribes, and predicted the destruction of Nineveh and the relief of Judah. He alludes twice to an overthrow of that city, and some have conjectured that he refers to two distinct captures, of which, however, only its final ruin by Cyaxares I. and Nabopolassar in 625 B. C. is historical.

NAIADS (Gr. *naai*, to swim), in Grecian and Roman mythology, nymphs who presided over fresh waters, and were supposed to inspire those who drank of them with oracular powers and the gift of poetry. They could also restore sick persons to health. They are represented in works of art as beautiful maidens, half draped, and with long hair.

NAIL (Sax. *nagel*; Ger. *Nagel*), a piece of metal, more or less sharp at one end with a head at the other, used to fasten together pieces of wood or other material by being driven into or through them. The principal division of nails is into wrought and cut, the former being made from tough wrought iron, the latter from rolled plates. The different sorts of nails are named either from the use to which they are applied or from their shape, as shingle, floor, ship carpenters', and horse-shoe nails, rose-heads, diamonds, &c. The small, sharp nails used by saddlers and others are called tacks. The small, sharp, taper nails, without heads, used by shoemakers, are sprigs. Those used for nailing floors and ceilings, with head only on one side, which in the cut nail is made in the operation of cutting, are brads. Very large nails are called spikes. The term penny, when used to mark the size of nails, is supposed to be a corruption of pound. Thus, a 4-penny nail was such that 1,000 of them weighed 4 pounds, 10-penny such that 1,000 weighed 10 pounds, &c. Originally, the "hundred" when applied to nails was 6 score or 120; consequently the thousand was 1,200.—The making of nails is one of the oldest of the handicraft arts, probably dating as far back as the art of working metals. Before the invention of machinery an immense number of persons were employed in making the nails required for use, there having been no fewer than 60,000 nailers in the neighborhood of Birmingham alone. It is only within the last 60 years that machinery has been employed to supersede to any extent hand labor in nail making. However, one of the earliest grants from the British patent office was in 1618 to

Clement Dawbeny for an "engine, worked by water, for cutting iron into small bars or rods for making nails." Afterward other machines were invented for forging and drawing nail rods, the form in which the nailer receives the iron. The nailer requires for his trade a small forge fire, an anvil, and several hammers and heading tools, or bores, for the different sorts and sizes of nails. In the United States the making of wrought nails is commonly a part of the blacksmith's business, except the larger bolts and spikes of wrought iron, which are now generally made by machinery. The end of the nail rod is first heated in the forge fire, the smith having two or more rods in at the same time, according to his skill. The body of the nail is then formed on the heated end, and cut off by a chisel fixed in the anvil block. While still hot the nail is placed in a bore, or heading tool, and the head fashioned with the hammer. The bore is a piece of strong iron with a steel knob at each end, perforated to the size of the shank of the nail, and countersunk to correspond with the head. About 1790 the first machine for dispensing with hand labor in nail making was invented in England. It was however only proposed to use water, or other mechanical power, to move hammers and other appliances for making nails similar to those made by hand. The next step in advance was the machine of Thomas Clifford of the city of Bristol, patented in 1790. He used two iron rollers, faced with steel, in which were sunk impressions, or forms of the nails, half of the form being in each roller, and arranged circumferentially, so that a bar of iron, being passed between the rollers, came through a string of nails, the head of one nail being slightly joined to the point of the next; these were then separated by shears or nippers. Sometimes several rows of indentations were made in the surface of the rollers, and, instead of bars, a slip of sheet iron was passed through, and being forced into the dies was formed into nails. Still another method was to form nails by casting, but these were too brittle to be of much service.—Nails made by either of the processes already mentioned were very expensive, and in the United States, where so many wooden structures had to be erected by the settlers, the obtaining of cheap nails was of the utmost importance. It was under the stimulus of this pressing necessity that about the year 1790 ingenious men set to work to invent nail machines. It is difficult at the present day to ascertain who it was that first conceived the idea of cutting nails from slips or rolled plates of iron. At first the nails were cut from a slip or hoop, and headed by a few blows of a hammer while grasping them in a vice worked by the foot. But very soon the machines were made to cut and head the nail at one operation. Between 1794, the date of the first patent, and 1817, more than 100 patents had been issued for nail machines and improvements. The first patent was for a machine for cutting nails,

March 28, 1794, to Josiah G. Person, or Pearson, of New York. Jan. 16, 1795, Jacob Perkins of Boston obtained a patent for a cutting machine. The following year patents were issued to Peter Cliff and to Amos Whittemore of Massachusetts, and to Daniel French of Connecticut. The first patent for a cutting and heading machine (Nov. 11, 1796) was granted to Isaac Garretson of Pennsylvania; and on Dec. 12, 1796, a patent for a similar machine to George Oandler of Maryland. Afterward several patents were granted to Jesse Reed, Samuel Rogers, and Melville Otis of Massachusetts, to Mark and Richard Reeve of Philadelphia, to Roswell Noble of Baltimore, and others. The machine invented by Jesse Reed, with some later improvements, is that still most largely used. The manufacture of cut nails was soon established in Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, and Maryland. In 1810 Joseph O. Dyer of Boston, but then a merchant in London, took out patents in England for the nail machinery invented in Massachusetts, and large manufacturing establishments were soon put in operation. Some in the neighborhood of Birmingham are able to make over 40,000,000 nails per week. In 1856 there were in the United States 2,645 machines, producing 81,462 tons of nails. It is quite possible that the persons mentioned above were not the first to invent machines for cutting nails. In "Hunt's Merchants' Magazine" it is stated that Benjamin Cochran, a shop mate of Eli Whitney, who died at Batavia, N. Y., in 1846, made the first machine of the kind about 1790. Many of the first inventors spent large sums of money on their machines. It has been estimated that it cost more than \$1,000,000 to bring them to the perfection arrived at in 1810, when a machine made about 100 nails per minute. It was at this time that the full value of this American invention was brought prominently before the world in the well known report of Albert Gallatin, then secretary of the treasury. Large nail factories were early established in different parts of Massachusetts, and at Ellicott's Mills, near Baltimore. At the present day the business is carried on very extensively in the Schuylkill iron region of Pennsylvania. There the pigs from the furnace go immediately to the bloomary, thence to the rolling mill, and so on through the slitting and nail cutting machines, so that all the operations from the crude ore to the finished nail are carried on at the same place.—During the year ending June 30, 1859, the exports of nails from the United States amounted to 4,686,207 lbs., valued at \$188,223; and the imports to 860,866 lbs., valued at \$34,504.

NAIN, a town of Palestine, mentioned in the New Testament (Luke vii. 11-17) as the place where Jesus raised the widow's son to life. It is situated on the N. slope of Little Hermon, in the pashalic of Akka, separated from Mt. Tabor by the brook Kiahon,

48 m. from Jerusalem and 8 m. from Nazareth. It is now an insignificant hamlet of a few families, and is called Nein.

NAIRNSHIRE, a maritime county of Scotland, bounded N. by the Moray frith, E. and S. by Elginshire, and W. by Inverness-shire; area, about 215 sq. m.; pop. in 1851, 9,956. The coast, about 10 m. in extent, is low, sandy, and dangerous. The inland districts are hilly and wooded; those on the sea are well cultivated and productive. The chief rivers are the Nairn and Findhorn. The climate is severe but healthful. Capital, Nairn.

NAKHITOHEVAN, a town of European Russia, in the government of Ekaterinoav, on the right bank of the Don, 7 m. E. N. E. from Rostov; pop. in 1851, 14,166, mostly Armenians. It stands on an eminence, has manufactures of cotton and silk, and maintains an extensive traffic with Circassia, Astrakhan, Turkistan, and Constantinople, especially in pearls and precious stones. The town was founded in 1780 by a colony of Armenians, and is the seat of the Armenian patriarch of Russia.

NAKHSIVAN (anc. *Naxuana*), a city of Russian Armenia, on a plateau near the left bank of the Aras, 83 m. S. E. from Erivan, and 175 m. S. from Tiflis; pop. about 5,000. The Armenians regard it as the most ancient city in the world, and as the spot where Noah settled after the deluge; and it formerly contained, according to the Persian annalists, 40,000 houses. In 1840 it was partly destroyed by an earthquake.

NAMES, words by which single objects are denoted. In this article we shall treat only of the names of men, which are commonly termed proper names. These are divided into baptismal or Christian names, and family names or surnames. It is probable that all names were originally significant, though in the lapse of time and the decay of languages the meaning of many of them has been lost. The most ancient names which have come down to us, as for instance those of the early Hebrews, are distinguished for simplicity, a single word only, with rare exceptions, constituting the name, as Abraham, Moses, Aaron, David, and Solomon. The most ancient names of women are equally simple, and with significations peculiarly suited to the female sex, as Rachel, ewe; Deborah, bee; Tamar, palm tree; Hannah, favor, or favorable. The Egyptians, Assyrians, Babylonians, Persians, and Greeks had no surnames. But in Italy, at least in those parts which the Greeks had not conquered, as among the Etruscans, family names were in use, preceded or followed by an individual denomination. The Romans adopted the same system of nomenclature, and also many Etruscan names, as Horatius, Livius, Aulus, Marcus, Publius, Severus. Their system of names was very complete. The whole commonwealth was divided into clans called *gentes*, each of which was subdivided into several families. Thus in the gens Cornelia were included the families of the Scipiones, Lentuli,

Oethegi, Dolabellæ, Cinnæ, Syllæ, and others. To mark the different gentes and families, and to distinguish the individuals of the same race, they had usually 3 names, viz., the *prænomen*, the *nomen*, and the *cognomen*. The *prænomen* denoted the individual, the *nomen* marked the gens, and the *cognomen* distinguished the family. Thus, in the name Publius Cornelius Scipio, Publius was what we now call the Christian or given name, Cornelius indicated the clan or gens, and Scipio showed that the individual belonged to the Scipio family of the Cornelli, which derived its name from the pious Scipio, who from his practice of leading about his blind old father was figuratively called *scipio* or the staff. Successful military commanders were sometimes complimented by the addition of a fourth name or *agnomen*, often commemorative of their conquests, as Coriolanus, Africanus, Germanicus. Complexion and other personal qualities often gave rise to cognomens among the Romans, as Niger, black; Paulus, little; Calvus, bald; Oocles, one-eyed; Flaccus, flapped; Fronto, heavy-browed. The order of birth originated others, as Quintus, the fifth; Septimus, the seventh. Some were derived from the time of nativity, as Martius, Maius. The use of surnames in modern times is of comparatively recent origin. As Christianity triumphed over paganism in Europe, the old pagan names were laid aside, and new names derived from Scripture or from church history were given to the converts, sometimes a whole company to save trouble being baptized by the same name, so that Paul, Peter, John, Mary, Margaret, and similar appellations, became so common as to create great confusion and inconvenience. For several centuries nicknames derived from occupations or from personal qualities were used; but as population advanced even these became insufficient, and at length recourse was had to the present system of surnames. Camden and other authorities concur in the opinion that hereditary surnames were not used in England before the Norman conquest; but Mr. Lower, in his "Essays on English Surnames," expresses the opinion that they were not altogether unknown before that epoch. Surnames among the Saxons were in fact sometimes formed from the father's name; as for instance in 804 we find Egbert Edgaring, or Egbert the son of Edgar, *ing* signifying progeny or descendant. Such names as Dering, Browning, Whiting, are supposed to owe their origin to this source, and to mean respectively dear, tawny, and fair offspring. White, Black, Red, Brown, Grey, Good, Cunning, and other characteristic terms were also used as surnames, as we find in the life of Hereward the Saxon the following persons mentioned: Martin Light Foot, so called from his agility; Siward the Red, Wulric the Black, and Leofric Prat or "the Cunning." The place of residence gave rise to some surnames among the Saxons, and became after the conquest one of the most prolific sources of the present English names. A

great many surnames occur in Domesday book, some of which are local, as De Grey, De Vernon; some patronymical, as Richardus filius Gisleberti (Richard, Gilbert's son); and others official or professional, as Gulielmus Cameraarius (William the Chamberlain), Radulphus Venator (Rodolphus the Hunter), and Gislebertus Cocus (Gilbert the Cook). But it was not until after the 11th century that the practice of making the second name of an individual stationary and transmitting it to descendants began to come into common use. By the middle of the 12th it began to be thought essential that persons of rank should bear some designation in addition to the baptismal name. A lady in the reign of Henry I. is represented by Robert of Gloucester as objecting to marrying a natural son of that king because he had no surname, upon which the monarch gave him the surname of Fitz-Roy, a designation which has often since been given to the illegitimate offspring of the English sovereigns. The prefix of Fitz, a corruption of *filis* (Lat. *filius*), son, was common among the Normans, as Fitz-Gilbert, Fitz-Gerald, Fitz-Henry, Fitz-Hugh. To this day the Russians employ a similar form by the addition of *vitch* to their names, as Paul Petrovitch (Paul the son of Peter); a practice also common among the Servians and other Slavic nations. During the middle ages many surnames were formed among the Jews in like manner by using the Hebrew *ben* or Arabic *ibn*, as for instance Solomon Ben-Gabirol (Solomon the son of Gabirol), a poet of the 11th century; and Abraham Ibn-Esra (Abraham the son of Esra), a philosopher of the same period. The existing well known Jewish name of Bendavid had its origin in the same custom. In Wales, until a recent period, *ap* or son was the only surnominal adjunct used, as David ap Howell, Evan ap Rhys, John ap Richard, names which are now corrupted into Powell, Price, and Pritchard. Many names beginning with P now in common use in England and America can be traced to this Welsh origin, as Pumphrey from Ap Humphrey, Parry from Ap Harry, and Pugh from Ap Hugh. It was not unusual in Wales even as lately as the middle of the 17th century to hear of combinations carried up through several generations, as Evan ap Griffith ap David ap Jenkin ap Hugh ap Morgan ap Owen, so that a man carried his pedigree in his name. In forming surnames from the patronymic the Welsh did not, like the English, use an affix, as John Adamson, but put the paternal name in the genitive, as Griffith William's, or as now written Williams, David John's or Jones, Evan Harry's or Harris. In consequence of this custom, and of the fewness of personal or Christian names, their adoption as surnames has become common to so many families that Wales to this day suffers under the inconvenience and confusion of a paucity of names. In Scotland, among the Gaelic inhabitants, the term *mac* was used in the same manner as the *ben* of the Hebrews and the *ap* of the Welsh,

to signify son of, as Macdonald and Macarty, meaning respectively the son of Donald and the son of Arthur. The Irish also used *mac* for the same purpose, as well as *oy* or *O'*, signifying grandson, as O'Hara, O'Sullivan. It has been asserted that in the reign of Edward II. an attempt was made by act of parliament to enforce the practice of using family names in England; but as population increased it is probable that common convenience led necessarily to their use. The Anglo-Saxons had a great variety of baptismal names, which mostly became obsolete after the conquest, being superseded, by Scripture names introduced by the Normans, such as John, James, Thomas, and Peter, which soon became so numerous that surnames were indispensable. They were not well settled, however, among the lower and middle classes until after the reformation, when the introduction of parish registers of births, deaths, and marriages contributed greatly toward giving them permanence. But so late as the beginning of the 18th century many families in Yorkshire had no fixed surnames. Even at this day it is said that few of the miners of Staffordshire bear their fathers' names, but are only known by some sobriquet. Nicknames, in fact, prevail so extensively among the colliers, that for every-day purposes no other names are used; and a man whose real name is John Smith may be known to his neighbors and even to his wife and children only as Nosey, Soaker, Lumper, Jiggery, or some such designation. A large class of English surnames are of local origin, and express the country or estate or residence of those who originally bore them, as Burgoyne, from Burgundy; Cornish, Cornell, Cornwallis, from Cornwall; Fleming, from Flanders; Gascoyne and Gaskin, from Gascony; Hanway, from Hainault; Janeway, from Genoa; Mayne, from the French province of Maine; Polack, from Poland; Wales, Welsh, Walsh, and Wallis, from Wales; Olare and Ross from those counties; Chichester, Rochester, Carlisle, Lincoln, Hastings, Huntington, Hull, Poole, and Wells, from those towns; Compton, Coombs, Clayton, Deane, Preston, Sutton, Waldron, and Washington, from villages in the county of Sussex. Camden remarks that there is not a single village in Normandy that has not surnamed some family in England. The French names introduced at the conquest may generally be known by the prefixes *de*, *du*, *des*, *de la*, *St.* or *Saint*, and by the suffixes *font*, *ers*, *faut*, *beau*, *age*, *mont*, *ard*, *aux*, *bois*, *ly*, *eu*, *et*, *val*, *court*, *lay*, *fort*, *ot*, *champ*, and *ville*. From Normandy came Mortimer, Warren, Percy, Gurney, Devereux, St. Maure (corrupted into Seymour). The names Hill, Dale, Forest, Wood, and the like, came from the nature or situation of the original bearer's residence. The prefix *atts* or *at*, softened to *a* or *an*, has assisted in the composition of many names; thus, if one dwelt on a moor, he would style himself Attemoor or Attmoor; if near a gate, Attegate or Agate." John

the Oaks was gradually corrupted into John Noaks; Peter at the Seven Oaks into Peter Snooks; Nash is a corruption of Atten-Ash, and Nye of Atten-eye, or at the island. *By* and *under* were used as prefixes to form names indicative of residence, as Byfield, Byford, Underhill, Underwood. The following are some of the words in old English which signify objects from which names frequently originated: *applegarth*, an orchard, whence Applegate, Appleton; *armitage*, a hermitage; *back*, a ferry, and also sometimes a wharf; *baine*, a bath, whence Bayne and Baynes; *barrow*, a hill; *berton*, a curtilage or courtyard; *beck*, a brook; *beat*, a plain or common; *borough*, whence Boroughs, Brough, Burg, Burke, and Borrow; *bottom*, low ground or valley, whence Shufflebottom, originally Shaw-field Bottom, and Higginbottom, from *hickin*, the mountain ash; *bridge*, whence Bridges and Briggs; *chase*, a forest or hunting ground; *clise*, a cliff, whence Cleve or Cleave; *clough*, a ravine or narrow glen; *codd*, a harbor; *garth*, a yard; *garneith*, a granary; *gore*, a narrow slip of ground, a word still used in that sense in America; *grange*, a farm, whence Granger; *holme*, *holmes*, a meadow surrounded by water; *holt*, a grove or hill covered with trees; *knapp*, the top of a hill; *lee*, *lea*, *leg*, *leigh*, a pasture; *lynch*, a thicket; *marck*, a boundary; *penn*, the top of a hill; *peel*, a moated fort; *rove*, a street; *rose*, a heath, a morass; *shaw*, a small wood or copse; *stead*, a place; *stowe*, a place; *thorpe*, a village; *wade*, a meadow, and also a ford; *weller*, a hollow or gulf; *wold*, an undulating country; and lastly *gate*, a gate, whence Yates. "After these local names," says Camden, "the most in number have been derived from occupations or professions." Of these the most notable is the name of Smith, the root of which is the Anglo-Saxon *smitan*, to smite. It was applied originally not merely to blacksmiths, but also to wheelwrights, carpenters, masons, and smiters in general. The "Saxon Chronicle" speaks of "mighty war smiths who overcame the Welsh." Nasmyth is probably a corruption of nail smith. Arrowsmith was a maker of arrow heads. Smith in Gaelic is *gow*, and the Gows were once as numerous in Scotland as the Smiths in England. Many of them in modern times have translated the name to Smith. McGowan is the same as Smithson. Among the names derived from occupations, the most common ones explain themselves, as for instance Mason, Baker, Butler, Coleman (coalman), Taylor, Draper, Farmer, Shepherd, Chapman (a trader, chepe-man, from *chepe*, a market), Cowper (cooper), Cutler, Wheeler, Miller, Gardner, Cook, Porter, Mercer, and Fidler. Sutor, a name still known in England and America, is the Latin, Saxon, and old English for shoemaker. Latimer is from *latiner*, a writer of Latin; Barker means tanner; Jenner is an old form of joiner, and Milner of miller. Lorimer is a maker of spurs and bits for bridles; Arkwright, a maker of chests; Lander, a contraction of *leandier*,

a washerman; Tucker, a fuller; Banister, the keeper of a bath; Kidder, a huckster or peddler; Wait, a minstrel; Crooker, a maker of pottery; Tupman and Tupper, a breeder of tups, that is, rams, or perhaps a maker of tubs. Hopper had the care of swans, the searching for and marking swans being called swan-hopping; the word also in Anglo-Saxon meant a dancer. Lardner is an obsolete word for swineherd. Many of this class of names have the Anglo-Saxon feminine termination, as Baxter and Bagster, the feminine of baker; Webster, of Webber or weaver; Brewster, of brewer. This is owing to the fact that these occupations were first followed by women, and when men began to invade them they kept the feminine appellations for some time, as men-milliners now do. The trade of weaving has been carried on by a Sussex family named Webb since the 13th or 14th century. From offices and dignities many English surnames are derived, as for instance King, Prince, Earl, Lord, Knight, Bishop, Prior, Abbot, Pope, Priest, Deacon, Squire, Franklin, Bailey, Chamberlain, Falconer, Leggett (legate), and Steward or Stuart. Many of these names were doubtless given to bastards or applied in jest, especially those of Pope, King, Bishop, and Abbot. From *dispensator* or dispenser, a steward, comes Spencer. Grosvenor anciently held the place of *gros veneur* or grand huntsman to the dukes of Normandy. Sumner was a summoner, who cited delinquents to the ecclesiastical courts. The termination *ward* indicates a keeper, as Durward, a doorkeeper; Hayward or Hereward, a keeper of the town cattle; Woodward, a forest keeper. Color and complexion have given rise to such names as Black, White, and Brown. As no person ever had a green face, the name Green must have been given on account of the bearer's verdancy, or from the local circumstance of living near the village green or common. The very common name Read, Reed, or Reid is an old spelling of red. Gray, Hoar, Long, Short, Longfellow, Longman, Tallman, Small, Strong, Lightfoot, and Heavyside are from personal characteristics. Hubbard and Joyce, the one Anglo-Saxon, the other French, were persons of a joyous nature. Hogarth is from the Dutch, high-natured, generous. Rush is subtle; Barrat, cunning; Bowne, ready; Bonner, kind, gracious; Eldridge, wild, ghastly. Many Welsh names naturalized in English are from personal characteristics, as More, great; Duff, black; Vaughan, little; Mole, bald; Fane, slender; Gough, red. Beside the Christian or baptismal names that have been taken as surnames, as Thomas, Henry, and Andrew, Bennett is derived from Benedict, Bryant from Brian, Emerson, Emery, and Amery from Almerie, Austin from Augustine, Durant from Durandus (whence also the Italian Durante or Dante), Ellis from Elias, Everett from Everard, Hode, Hoad, and Hood from Odo or Otho, Hamlin from Hammeline, Jarvis from Gervaise, Stiggins from Stigandus or Stigand, Terry from Theodoric, Tudor from Theo-

dore. A single Christian name has sometimes given rise to many surnames, as from William came the following: Williams, Williamson, Wills, Wilks, Wilkins, Wilkinson, Wickens, Wickeson, Bill, Bilson, Wilson, Woolcock, Woolcot, Wilcooke, Wilcox, Wilcockson, Wilcoxon, Willet, Wilmot, Willy, Willis, Wyley, Willott, Till, Tillot, Tilson, Tillotson, Tilly. Many surnames, apparently meaningless in the present English, were significant in old English and in provincial dialects. For example, Brock means a badger, Todd a fox, Talbot a mastiff, Culver a pigeon, Bisset a wild pigeon, Henshaw a young heron, Coke a cook. Fisk is the Anglo-Saxon form of fish. Such names as Lyon, Leopard, Hawke, Raven, and Heron have been taken from the devices on shields and signs. Camden says: "Many names that seem unfitting for men, as of brutish beasts, &c., come from the very signs of the houses where they inhabited; for I have heard of them which said they spake of knowledge, that some in late time dwelling at the sign of the Dolphin, Bull, Whitehorse, Rocket, Peacock, &c., were commonly called Thomas at the Dolphin, Will at the Bull, George at the Whitehorse, Robin at the Rocket; which names, as many others of like sort, with omitting at, became afterward hereditary to their children." Such, too, was doubtless the origin of the names Homer, Tully, Cato, and Cæsar, whose effigies on booksellers' and other shops have given rise to surnames yet used in England.—Nearly all that has been said of English surnames is applicable to those of the United States, where however a few peculiar names have been formed by corruption or translation of foreign names, as Bunker from the French Bon Œur, Bumpus from Bon Repos, Bellows from Belle Eau, and Cisco from Francisco. A vast number of Dutch, German, French, Swedish, and Norwegian names have been introduced by the foreign immigration. The Dutch names are most common in the state of New York, and those of the north of Europe in the N. W. states. The aboriginal languages have contributed a little to the American stock of surnames, the civilized tribes, as those of New England and New York and the Creeks, Cherokees, and Choctaws, having generally adopted their use; and the African languages have also supplied a few, as for instance that of Cuffee, which has been borne by a noted sea captain, and his son, a preacher of the gospel.

NAMUR, a province of Belgium, bounded N. by Brabant, N. E. by Liège, E. by Luxembourg, S. by France, and W. by Hainault; area, 1,411 sq. m.; pop. in 1856, 286,075. The principal rivers are the Meuse, Sambre, and Lesse. The surface is very much diversified, and the soil is in general fertile. Iron, lead, coal, and marble are mined. The number of coal mines in operation in 1857 was 28. This province is divided into 3 arrondissements, Namur, Dinant, and Philippeville, which are subdivided into 15 civil and 16 military cantons.—**NAMUR**,

the capital, is situated at the confluence of the Sambre and Meuse, 67 m. S. E. from Brussels; pop. in 1856, 22,218. It is strongly fortified. The cathedral, a modern structure, is ornamented in front with 20 Corinthian columns, and beside the great altar stand colossal statues of the apostles Peter and Paul. The staple manufactures are cutlery, for which Namur is famous, and leather, which occupies nearly $\frac{1}{4}$ of the population. The town was taken by Louis XIV. in 1692, and by William III. of England in 1695. In 1784 Joseph II. of Austria demolished its fortifications, which in 1817 were restored by the king of the Netherlands.

NANCY, a city of France, capital of the department of Meurthe, on the left bank of the river Meurthe, 220 m. E. from Paris; pop. in 1856, 48,452. It stands in a beautiful and fertile plain, and consists of an old and a new town. The many fine edifices, squares, and promenades render Nancy one of the handsomest of French towns. The chief edifices are the cathedral, a handsome modern structure, with two towers over 250 feet high; the church of St. Epore, which contains several fine paintings, and a fresco attributed to Da Vinci; the church of the Cordeliers, in which is the mausoleum of the dukes of Lorraine; an ancient Gothic castle, now a barrack; the university, which has a library of 28,000 volumes; the theological college; the museum, with pictures by Isabey, a native of Nancy, and other works of art; a medical institute, and hospitals. Hosiery, muslin, cotton yarn, woolen cloth, calico, lace, &c., are manufactured. There are 8 fairs yearly, one of which lasts 20 days. Nancy was the capital of the duchy of Lorraine from the 13th century till its absorption by France; and under its walls Charles the Bold, duke of Burgundy, was defeated and slain in 1477 by René II., duke of Lorraine.

NANDOU. See **OSTRION**, of which it is a South American species.

NANKEEN, a fabric manufactured in China of a buff-colored cotton, and much esteemed for its durability and the permanency of its hue, which is natural to the material and not the effect of a dye. Imitation nankeens have been largely manufactured in Manchester, England, by dyeing the white cotton, and they have even been exported to Canton; but they are much inferior to the genuine Chinese article.

NANKING, or **NANKIN** (i. e., the "southern capital," in distinction from Peking, the "northern capital"), called also **KIANG-NING-FU**, a city of China, the chief town of the province of Kiang-su, and the residence of the governor-general of 8 provinces, situated about 3 m. S. of the Yang-tse-kiang river, 90 m. from its mouth, and on the grand canal connecting Canton and Peking, in lat. 32° 2' N., long. 118° 49' E.; pop. estimated by Ellis at 400,000, which is probably under the true amount. The river opposite the city is $1\frac{1}{2}$ m. broad and 25 fathoms deep, with a rocky bottom, and a current of from 3 to 5 m. an hour. Though the city lies

8 m. from the bank of the Yang-tse-kiang, a part of the walls, which are 18 m. in circumference, approach within 700 yards of the water. The principal streets are of moderate breadth, clean, well paved, and lined with handsome shops; but the houses are in general mean, and only one story high. This city was formerly the capital of China, and of much greater extent than at present; but since the conquest of the empire by Kublai Khan, in the latter part of the 13th century, and the removal of the imperial residence to Peking, it has very much declined. The part of Nanking occupied by the Mantchoos is separated by a cross wall from the Chinese town. The most remarkable structure in Nanking was the pagoda called by Europeans "the porcelain tower," built A. D. 1411-'80, of an octagonal form, 261 feet high, in 9 stories, each adorned with a cornice and gallery, and covered with a roof of green tiles, with a bell suspended at each corner that sounded when moved by the wind. On the top was a pinnacle in the shape of a pineapple, surmounted by a gilded ball; and a spiral staircase inside led to the summit. This famous edifice was blown up by the Tai-ping rebels in 1856. In the city there are extensive manufactures of satin and crape, and of the cotton cloth known as nankeen. Paper and ink of fine quality, and beautiful artificial flowers of pith paper, are also made. Nanking is celebrated for its scholars and its literary character, having many large libraries and booksellers shops.

NANSEMOND, a S. E. co. of Va., bordering on N. C. and the Dismal Swamp, and drained by branches of the Nansemond river; area, 444 sq. m.; pop. in 1850, 12,283, of whom 4,715 were slaves. It has a level surface and sandy soil. Lumber, tar, and turpentine are exported in considerable quantities. The productions in 1850 were 352,842 bushels of Indian corn, 186,324 of sweet potatoes, 8,671 lbs. of wool, and 3,338 tons of hay. There were 7 saw mills, 4 grist mills, 1 cotton mill, 19 churches, and 298 pupils attending public schools. The value of real estate in 1856 was \$1,708,654, showing an increase of 16 per cent. over 1850. The Portsmouth and Roanoke railroad passes through the capital, Suffolk.

NANTASKET, a narrow peninsula about 5 m. long, extending into Massachusetts bay, in Plymouth co., Mass., about 22 m. from Boston by railroad and 9 m. by water. It is a favorite summer resort on account of its fine facilities for sea bathing. This peninsula comprises the town of Hull, which was settled about 1625, and in 1855 had 292 inhabitants.

NANTES (anc. *Condivincum*), a maritime city of France, capital of the department of Loire-Inférieure, on the right bank of the Loire, 270 m. S. W. from Paris; pop. in 1856, 108,530. It is partly situated on the mainland, partly on 3 islands formed by the branches of the Loire. The principal edifices are the cathedral of St. Pierre, the castle, a vast Gothic

pile, the exchange, theatre, court house, museum, college, medical institute, infirmary, and a library of 80,000 volumes. The quays are magnificent, extending along the Loire and Erdre nearly 2 m., lined with trees and adorned with elegant mansions. There are considerable cotton and woollen manufactories. Nantes is the seat of a bishop. It is a place of great antiquity, having been in pre-Roman times the capital or principal stronghold of the Nannetes or Namnetes. In the middle ages it was the capital of the dukedom of Brittany, which became united to France through the marriage of Anne, the last duchess, to Charles VIII. It subsequently became the head-quarters of the Huguenots, and here was promulgated in 1598 the famous edict of Henry IV., which secured religious liberty to the French Protestants. The edict was revoked by Louis XIV., Oct. 22, 1685.

NANTUCKET, the southeastermost co. of Mass., comprising the island of Nantucket, together with the small islands of Tuckanuck, Muskejet, and the Gravel islands, lying in the Atlantic ocean; total area, 60 sq. m.; pop. in 1855, 8,064; in 1860, 6,100, nearly all included in the town of Nantucket. The principal island, Nantucket, is of an irregular triangular form, about 15 m. long E. and W., with an average breadth of 4 m., and an area of 50 sq. m. It has a level surface to the S., and is hilly in the N.; the soil is generally sterile, and much of the land held in common. In 1855 it contained 7 establishments for the manufacture of oil and sperm candles, producing 970,828 galls. whale and 67,516 galls. sperm oil, value \$768,529, and 142,450 lbs. of sperm candles, value \$17,405; 2 soap and candle factories, and various other establishments. The agricultural productions were 7,980 bushels of Indian corn, 7,776 of potatoes, 7,752 of turnips, 24,152 lbs. of butter, and 8,029 of wool. In 1850 there were 9 churches, 2 newspaper offices, and 1,230 pupils attending public schools. On the S. E. of the island are the Nantucket shoals, about 50 m. long by 45 wide, on which many vessels have been wrecked. The island was first settled by whites in 1659, when Thomas Macy, to escape persecution, took refuge there with his family, having purchased it for £30 and 2 beaver hats.—**NANTUCKET**, the capital of the above county, is situated on the N. side of the island, lat. 41° 16' 56" N., long. 70° 06' 12" W., 50 m. S. E. from New Bedford, and 105 m. S. S. E. from Boston. It has a deep and secure harbor, formed by two projecting points of land, on one of which is a lighthouse, with an entrance about $\frac{1}{4}$ m. wide. The bar has $7\frac{1}{2}$ feet at low water. It is principally noted for its connection with the whale fisheries, of which at one time it was the leading mart in the world. In 1673 a license was obtained by one of the inhabitants, by which he was permitted to carry on the whale fishery on payment of 5 shillings for each whale caught, those animals then being numerous on the coast and successfully pursued from the shore in boats. Subsequent-

ly large vessels were employed and voyages made for the purpose, and this great industry opened to the competition of the world. As early as 1746 ships were sent as far as Davis's straits, and in 1774 to the coast of Brazil. The first ship that went on a whaling voyage to the Pacific ocean sailed from Nantucket in 1791. At the time of the breaking out of the war of the revolution there were 150 vessels belonging to the island engaged in the business; and after its close the flag of the new republic was first seen in the river Thames flying at the masthead of a Nantucket ship. For the last 20 years the prosperity of the town has been diminishing. Its aggregate tonnage, which in 1844 was 27,280, in 1859 was only 12,284, of which 10,297 was engaged in whaling. In 1846 a conflagration destroyed 850 buildings, valued with their contents at \$900,000. In 1855 the receipts of sperm oil were 175,700 galls., value \$251,572; of whale oil, 261,789 galls., value \$146,049; of whalebone, 81,752 lbs., value \$32,806. There were 44 vessels employed, with a tonnage of 14,266, and a capital of \$1,482,600. The village of Biasconset, at the S. E. extremity of the island, 7 m. from the town of Nantucket, is a noted watering place, and is much resorted to in the summer by invalids.

NAPA, a N. W. co. of Cal., drained by Napa and Los Putas rivers; area, 560 sq. m.; pop. in 1858 estimated at 4,500. The surface is diversified, but generally fertile and well adapted for cultivation. The Coast range of mountains extends along the S. W. border, and Mount St. Helen, at the head of the Napa valley, attains an elevation of 3,500 feet. It contains numerous medicinal springs, constantly increasing deposits of sulphur, two lakes yielding large quantities of borax, geysers or hot springs about 60 m. N. of Napa City, and a "glass mountain," discovered in 1857, reported to be composed of materials susceptible of easy manufacture into that article; and a quicksilver mine has recently been opened. The productions in 1858 were estimated at 500,000 bushels of wheat, 150,000 of barley, 50,000 of oats, and 50,000 of Indian corn. In the same year 1,000 galls. of wine were made. There were 5 grist mills and 6 saw mills, and the assessed value of property was \$2,015,911. Capital, Napa City.

NAPHTALI (Heb., my wrestling), the 6th son of Jacob, by Bilhah the handmaid of Rachel. In the blessing which Jacob gave his children before he died, the patriarch called him "a hind let loose," adding that "he giveth goodly words;" a passage which has greatly perplexed commentators. In the allotment made to the tribes after the entrance into Canaan, the tribe of Naphtali received a part of upper Galilee on the W. of the Jordan, extending from Lake Gennesareth to the sources of the Jordan. It is distinguished in the song of Deborah for the alacrity with which it obeyed the call to arms against the oppressors of the Hebrews.

NAPHTHA, a term rather loosely applied

to mixtures of different hydrocarbons, which constitute either the natural rock oil (see PETROLEUM), or the different oils obtained by the destructive distillation of carbonaceous substances. It is sometimes limited to the lighter oils, and sometimes the heavy oils which come over last in the distillation are called heavy coal naphtha. Wood naphtha is the light volatile fluid first obtained in distilling crude pyroligneous acid. It is also known as wood spirit, pyroxylic spirit, methylic alcohol, and hydrous oxide of methyle, all which names are more appropriate than naphtha, as the compound is of alcoholic character, containing oxygen, which the true hydrocarbons do not, and is represented by the formula $C_2H_5.OHO$. The naphtha in use for preserving potassium and sodium from access of oxygen, and for a solvent of various gums and other substances, is obtained from petroleum or from artificially prepared coal oils by first treating them with sulphuric acid, and next with a caustic alkali, and then distilling off the more volatile portion, which is the naphtha, represented by the general formula C_2H_4 . But even this is a compound of hydrocarbons, Pelletier and Walter separating from it by distillation three liquids distinguished from each other by their composition and the degrees of their boiling points. They called these, in the order in which they were obtained, naphtha, $C_{10}H_{14}$, boiling point 194° ; naphthene, $C_{10}H_{16}$, boiling point 239° ; and naphthole, $C_{10}H_{12}$, boiling point 374° . The evident relation between the boiling points would seem to imply the existence of two other members of the series between the last two named.—As commonly described, naphtha is a very inflammable colorless liquid, of bituminous odor, tasteless, soluble in all proportions in absolute alcohol and in ether, insoluble in water, of specific gravity .700 to .847. It dissolves the fixed and essential oils in all proportions, and is hence advantageously used for removing grease from fabrics. It also dissolves sulphur, phosphorus, iodine, gum lac and copal, camphor, caoutchouc, the resins, &c.; a quality that adapts it for the preparation of varnishes, and for other similar uses in the arts. In its preparation from artificial coal oils it is found that those which produce paraffine yield in general naphtha, while the product of those which contain naphthaline is rather limited to the hydrocarbons of the benzole series. Naphtha has been used as a remedy in cases of consumption, and by some practitioners is preferred to cod-liver oil as a source of carbon.

NAPHTHALINE, a hydrocarbon ($C_{10}H_8$), obtained in crystalline plates or scales from the distillation of the last portions of coal oil derived from certain bituminous substances, generally from those which do not yield paraffine, though the two are sometimes produced from the same crude material. It is a substance but slightly soluble in hot water, but dissolves in the volatile oils, and in ether. It distils over with water, and in the open air evaporates like

camphor. It fuses at 176° into a colorless liquid, and boils at 418° . Its specific gravity is about 1.05.

NAPIER, SIR CHARLES, a British admiral, born in Merchiston hall, Stirlingshire, March 6, 1786, died Nov. 6, 1860. He was a grandson of the 5th Lord Napier and a descendant of the inventor of logarithms. He entered the navy in 1799 as a volunteer on board the sloop of war *Martin*; in 1805 was appointed lieutenant; in 1808 commanded the brig *Recruit* of 18 guns; and in April, 1809, for the gallant manner in which he aided in the chase of a French squadron, resulting in the capture of the *Hupolt*, 74, as also in the reduction of *Martinique*, he was made a post captain. He subsequently served a campaign with the British army in Portugal, and was present at the battle of *Busaco*; and between Nov. 1811, and June, 1815, he participated in numerous gallant exploits on the coast of southern Italy and the North American station. After a long period of inactivity he was in 1829 employed in special service on the coast of Portugal, and in 1833 was appointed by Dom Pedro to command the Portuguese fleet destined to operate against Dom Miguel. On July 3, 1833, he gained a signal victory over the enemy off Cape St. Vincent, capturing two ships of the line, a frigate, and a corvette, for which he was created Count Cape St. Vincent, grand cross of the tower and sword, and a grandee of the first class in Portugal; but having subsequently experienced unjust treatment from the Portuguese government, he returned to England, and, in Jan. 1839, was appointed to the command of the *Powerful*, 84. In the succeeding year he hoisted his broad pennant on board the ship, and became second in command under Sir Robert Stopford of the fleet employed on the coast of Syria. Among the important achievements in which he participated during the war with Mehemet Ali were the storming of Sidon and the capture of Beyroot and Acre, where his services, which he took care to estimate at their proper value, were of the most distinguished character. In the same year he was created a K.C.B., beside receiving several continental decorations; and subsequently he was appointed rear admiral of the blue, and held command of the channel fleet for two years. In 1849 he was superseded, but upon the breaking out of war with Russia he was put in command of the fleet destined to act against Cronstadt and other Russian ports in the Baltic. He sailed from Spithead, March 11, 1854, with the most magnificent fleet ever equipped by Great Britain, promising to take Cronstadt in a month, and, as an earnest of his intentions, telegraphed to his crews to "sharpen their outlasses," and signalled for large quantities of chloroform in anticipation of the many severe engagements likely to be encountered. His return to England in December, without having accomplished any thing of importance beyond the capture of Bomarsund, subjected him to considerable

ridicule, and led to many angry recriminations between himself and the Aberdeen ministry, by whom he complained that he had been fettered in the discharge of his duties. After that time he held no important command. As a controversial writer on subjects connected with his profession, he was distinguished by the pungency and personality of his remarks, by an overweening vanity, and frequently also by sterling common sense, particularly in his suggestions on the subject of naval reform, several of which, including those on the abolition of flogging and the introduction of a system of registration, have been adopted by the admiralty. A collection of letters on naval reform, contributed to the "*Times*" and other journals, was published by him in 1851 under the title of the "*Past and Present State of the Navy.*" He was also the author of "*Administration of Sinde*," the "*War in Portugal between Pedro and Miguel*" (2 vols. 8vo.), and the "*War in Syria*" (2 vols. 8vo.). In 1832 and 1837 he unsuccessfully contested the boroughs of Portsmouth and Greenwich; between 1841 and 1847 he represented Marylebone in parliament; and after 1855 he sat for Southwark. As a legislator he was an active debater on the liberal side. After 1858 he held the rank of admiral of the blue.

NAPIER, SIR CHARLES JAMES, a British general, born in Whitehall, London, Aug. 10, 1782, died at Oaklands, near Portsmouth, Aug. 29, 1858. At an early age he received an ensign's commission in the 4th regiment of foot, with which he first saw active service during the Irish rebellion of 1798. In 1806 he held the rank of major in the 50th regiment of foot, and two years later was ordered to the Peninsula, where he participated in the retreat of Sir John Moore, ending in the battle of Corunna. In this encounter, while leading a handful of men into the thickest of the fight, he received 5 severe wounds, and was left for dead in the hands of the enemy. By skilful treatment he was restored to health, and returned to England on parole in the spring of 1809, to the astonishment of his friends, who had already administered upon his estate. Not succeeding at once in procuring employment, he turned his leisure to account by writing pamphlets on a variety of subjects, his mind being of so active a character that "whenever he was not fighting he was writing." He finally went to the Peninsula as a volunteer, had two horses shot under him at Coa, and at *Busaco* received a ball in the jaw which he rode 100 miles to have extracted. In 1811 he procured through the influence of Wellington a regular command, and served with credit until the close of the war. Immediately afterward he was sent to Bermuda as lieutenant-colonel of the 102d regiment, and for some months participated in expeditions which harassed the coast of the United States. The return of Napoleon to France recalled him to Europe, but to his extreme disappointment he arrived a day or

two too late to participate in the battle of Waterloo. For several years subsequent he pursued a course of study at the military college of Sandhurst, and in 1825 was appointed governor of Cephalonia, where he remained 5 years, gaining the affections of the inhabitants, but failing to satisfy the ministry, by whom he was somewhat suddenly recalled. During this interval he was a correspondent and ally of Byron in the agitation for Greek independence; but his recommendations were disregarded by the Greek committee in London. After a long period of inactivity, he was appointed commander of the forces in the northern district of England, whence in 1841 he was transferred to the command of the army in Bombay. He commenced his Indian career by a number of sweeping reforms in the service, in which, being no respecter of persons, he encountered the dislike of his officers, many of whose luxuries and privileges he abridged or entirely abolished. Upon the arrival of Lord Ellenborough in India in Feb. 1842, as governor-general, he sketched out for him the plan of a second Afghan campaign; and in the early part of the succeeding year he was called upon to take the field against the ameers of Sind, who, deceived as to the strength and resources of the British government by the result of the Cabool expeditions, were beginning to assume a defiant attitude. The Sindian war, which Sir William Napier called "the tail of the Afghan storm," was commenced by a rapid march across a desert to the fortress of Emaun Ghur, one of the chief strongholds and magazines of the ameers, which was blown up—an exploit highly commended by the duke of Wellington in parliament, in moving a vote of thanks to Gen. Napier. On Feb. 17, 1843, with a force of less than 2,000 men, he attacked an army of 85,000 Beloochees at Meeanee (his maxim in Indian military operations being never to give way before barbarians, whatever might be the disparity of numbers), and after an obstinate conflict gained a complete victory with a loss of 270 killed and wounded. Upward of 6,000 of the enemy fell, most of whom were killed, as no quarter was given; and 6 of the ameers gave in their submission, surrendering at the same time the important fortress of Hyderabad. One of them, however, Shere Mohammed, called the "Lion," collected an army of about 25,000 men to oppose Napier, but was beaten at Dubba, near Hyderabad, June 8, with immense slaughter. The war being ended, Napier, who after the battle of Meeanee had been appointed by Lord Ellenborough a K.O.B. and governor of the conquered province, set to work to improve its condition. The Hindoo and Sindian population, who had long been subjected to the military despotism of the Beloochees, were protected in their commercial and agricultural pursuits, native industry was encouraged, and slavery and the slave trade, sutteeism, infanticide, the military tenure of lands, and other barbarous customs were abolished.

These reforms were conducted by Sir Charles in spite of frequent severe sicknesses and of the intrigues of interested parties, and during the course of his administration he visited every portion of Sind. At the breaking out of the first Sikh war in 1845 he organized a force of 15,000 men to operate against the enemy, but was ordered elsewhere before the commencement of the campaign. In 1847 he returned to England, where he met with a flattering public reception. After a brief season of repose, he was, in March, 1849, at the suggestion of the duke of Wellington and in accordance with public feeling, despatched to India as commander-in-chief of the British forces, to supplant Lord Gough, whose doubtful victory at Ohillianwallah in the second Sikh war had created much alarm in England. He found the war virtually ended before his arrival, and during the few months that he remained in the country he busied himself in military reforms and in repressing a mutinous spirit among the sepoys. "The most fiery of all the irascible tribe of Napiers," he came into collision with the governor-general, Lord Dalhousie, on some points of prerogative, and returned to England in 1850 dissatisfied and indignant. His health rapidly failed after this, his last public appearance being at the funeral of the duke of Wellington in Nov. 1852. At the time of his death he was a G.C.B., lieutenant-general in the army, and colonel of the 22d regiment. Among his numerous publications are some of permanent importance, including "Colonization in Southern Australia," "History of the Colonies—Ionian Islands," "Indian Misgovernment and Lord Dalhousie," "Lights and Shadows of Military Life" (a free imitation of Alfred de Vigny's *Grandeur et servitude militaires*), and "Remarks on the Military Law of Flogging." His career in India has been described by his brother Sir William F. P. Napier, who has also published his "Life and Opinions" (4 vols. 8vo., London, 1857). Monuments to him have been placed in Trafalgar square and St. Paul's church, London. He possessed the strong individuality which has characterized his family in the present century, was a good hater, warm in friendship, and persistent in enmity; and the consequence of such a character, developed in his busy career, was perpetual strife. He nevertheless accomplished much good in various departments of the public service, and during his last two years in India, according to the testimony of a recent writer, "the abuses which he corrected and the excesses which he restrained were perfectly numberless."

NAPIER, JOHN, laird of Merchiston, the inventor of logarithms, born at Merchiston castle, near Edinburgh, in 1550, died there, April 4, 1617. In 1562 he entered St. Salvator's college in the university of St. Andrew's, and subsequently passed several years in travelling in France, Italy, and Spain. On his return to his native country he did not mingle in active life, and but little is known of him until he had

arrived at the age of 40. In 1598 he published "A Plain Discovery of the Revelation of St. John" (4to., Edinburgh), and in the dedication of the work to the king gave his majesty some advice in regard to religious matters, and the propriety of reformation in his own "house, family, and court." A letter of his to Anthony Bacon, written in 1596, still exists, entitled "Secret Inventions necessary in those days for the Defence of this Island, and withstanding Strangers, Enemies to God's Truth and Religion." One of these inventions was for a burning mirror to set fire to ships by reflecting the rays of the sun; another was a device to accomplish the same purpose by reflecting "the beams of any material fire or flame;" another an instrument which should scatter such an amount of shot in all quarters as to destroy every thing near it. These and other schemes, if practicable, were never carried out, perhaps owing to the humane disposition of Napier himself, who declared on his death-bed that the "instruments of human destruction should never be increased by any conceit of his." Nothing is heard of him after this until in 1614 he brought out his system of logarithms, entitled *Mirifici Logarithmorum Canonis Descriptio* (4to., Edinburgh). Although published then, it is evident that Napier had begun the investigation of this subject before 1594, from a letter written by Kepler to Crugerus in 1624, in which he says: *Nihil autem Napierianam rationem casuato; etsi Scotus quidem literis ad Tycho-nem, anno 1594, scriptis jam epem fecit canonis illius mirifici*. No sooner was the work published than Henry Briggs, then professor of mathematics in Gresham college, London, began the application of the rules in his *Imitatio Napierae*, and the system proposed by him is now commonly used. Napier's last work was his *Rabdologia seu Numerationis per Virgulas libri duo* (12mo., Edinburgh, 1617), in which he explained a contrivance to facilitate multiplication and division by means of small rods, which invention goes under the name of Napier's bones. After his death was published his *Mirifici Logarithmorum Canonis Constructio* (12mo., Edinburgh, 1619), in which he explained the principle of the construction of logarithms. Napier also enriched the science of trigonometry by the general theorem for the resolution of all the cases of right angled spherical triangles. There are two lives of Napier: one by the earl of Buchan, containing an analysis of his works by Dr. Walter Minto, published in 1787; and another by Mr. Mark Napier, published in 1884.

NAPIER, HENRY EDWARD, an English naval officer and author, born March 5, 1789, died Oct. 13, 1853. He was the youngest brother of Sir Charles James Napier, the conqueror of Sinde, and at an early age entered the navy, where he attained the rank of captain. He is the author of "Florentine History from the earliest Authentic Records to the Accession of Ferdinand III., Grand Duke of Tuscany" (6 vols 12mo., London, 1846-'7), an original work

of great merit, and the most elaborate of the kind in the English language.

NAPIER, MACVAY, a Scottish miscellaneous writer, born in 1776, died Feb. 11, 1847. He was educated at the universities of Glasgow and Edinburgh, and, being destined for the legal profession, was apprenticed to a member of the society of writers for the signet, was elected librarian of the society, and subsequently was selected for a lectureship on conveyancing, which was afterward made a professorship in the university of Edinburgh. In 1814 he edited the "Supplement to the Encyclopædia Britannica," and afterward superintended the 7th edition of that work. In 1829 he succeeded Jeffrey in the control of the "Edinburgh Review," which position he held 17 years. He published in 1818 "Remarks illustrative of the Scope and Influence of the Philosophical Writings of Lord Bacon," and was the author of some treatises on Scotch law.

NAPIER, ROBERT, a Scottish ship builder and engineer, born in Dumbarton, June 18, 1791. Although the son of a blacksmith, he received a good education in his native town, but was unwilling to go to college, preferring to become an apprentice in his father's trade. In 1811 he went to Edinburgh, where with considerable difficulty he obtained work, and with still more difficulty managed to live upon his wages of 10s. 6d. a week for 9 months, after which time he was employed in manufacturing works. Here, attempting to make a steam boiler, he omitted to caulk the joints, and the boiler leaked so much in consequence that the fire was put out. Mortified at his ill success, he returned to his father, and afterward went to Glasgow, where he was employed a short time with Mr. W. Lang, who manufactured jacks and machinery for calender works. Receiving from his father in May, 1815, £50, he spent £45 of it in purchasing a blacksmith's establishment at the Gallowgate of Glasgow, and set up business for himself. In 1823 he constructed his first marine engine, the forerunner of a large number of works of a similar character. In 1830 Mr. Napier, in conjunction with the city of Glasgow steam packet company, established a line of vessels which remained unsurpassed till superseded by railways; in 1834 furnished the Dundee and London shipping company with the Dundee and Perth steamships; in 1836 the East India company with the Berenice; and, in addition to several other works, in 1840 supplied the Hon. Samuel Cunard with his first 4 steamers. He has since built 9 other Atlantic steamers, and in 1856 the iron steamship Persia of 3,600 tons. Frequently 3,000 men are now employed by the firm of Robert Napier and son. In spite of the numerous and vast contracts they have undertaken, no important accident has happened to the machinery or vessels of their construction. Mr. Napier received the great gold medal of honor at the Paris exposition of 1855, and the decoration of the legion of honor.

NAPIER, SIR WILLIAM FRANCIS PATRICK, a British soldier and author, born in Castletown, county of Kildare, Ireland, in 1785, died at Clapham Park, near London, Feb. 12, 1860. He entered the army at 15 years of age as ensign in the 48d regiment, was made a lieutenant in the succeeding year, and in 1804 a captain. After serving in the expedition to Copenhagen in 1807, he accompanied Sir John Moore to Spain in 1808, and during the next 6 years was an active participator in the war carried on in that country, his regiment forming part of the famous light division under Moore and Wellington. In 1811 he became major and in 1818 lieutenant-colonel of his regiment, which he commanded at Salamanca, Nivelle, and on the Nive. He was repeatedly wounded during the war, particularly at Almeida, and in following the retreat of Masséna from Portugal in 1810. Passing through the intermediate grades, he was appointed lieutenant-general in 1851, and general in 1859; and in 1858 he received the colonelcy of the 27th regiment. Between 1842 and 1848 he was lieutenant-governor of Guernsey, and in 1848 he was created knight commander of the bath. He is best known, however, as a writer, particularly of military history; and his chief work, "The History of the War in the Peninsula and in the South of France from 1807 to 1814" (6 vols. 8vo., London, 1828-'40), will prove an enduring monument of his industry and capacity. In the preparation of this work, which occupied him 16 years, he availed himself of communications from many distinguished officers, English and French, and was specially supplied with materials and documents by the duke of Wellington and Marshal Soult. Valuable assistance was also rendered him by his wife, a niece of Charles James Fox, who deciphered the secret correspondence of Joseph Bonaparte, which had been placed in his hands, and wrote out the whole work for the printers. The history, though technical in its details and severe in its style, has, in the words of a recent writer, "a dignity of treatment and a living verity in the descriptions which lead the mind irresistibly captive." The haughty and uncompromising spirit in which it was written nevertheless subjected the author to frequent charges of unfairness and inaccuracy, and for several years after its publication it was the subject of angry communications in the "Quarterly Review," the "United Service Magazine," and the "Times." The historian, however, refused to retract a single word, and in a number of controversial pieces, published as pamphlets or as review articles, vigorously defended his assertions. A selection from these in the appendix to the last English edition of his history, of which an American reprint was published in 1856 (5 vols. 12mo., New York), in the author's opinion, "will be found to sustain the accuracy of a work written honestly from good materials." In 1855 he published a volume entitled "English Bat-

ties and Sieges in the Peninsula," consisting principally of extracts from his large work, with some portions entirely rewritten. Sir William Napier also wrote the "Conquest of Sicinde" (8vo., 1845), giving an account of the military exploits of his brother, Sir Charles James Napier, and published the "Life and Opinions" of the same (London, 1857), a work which involved him in a controversy with the East India company. His fondness for controversial writing was also indicated by various articles in the "Westminster" and other reviews, and in his unremitting efforts in behalf of his brother, and of his cousin Sir Charles Napier, the admiral.

NAPLES, KINGDOM OF. See SICILIA, THE Two.

NAPLES (It. *Napoli*; anc. *Neapolis*), a city and seaport of S. Italy, in a province of the same name, on the N. coast of the bay of Naples, and on the river Sebeto, in the immediate vicinity of Mt. Vesuvius, and not far from the sites of Herculaneum and Pompeii, 118 m. S. E. from Rome, and connected by railway with Capua, Castellamare, and Cava; lat. 40° 52' N., long. 14° 15' E.; pop. of the city in 1856, 413,920, and of the province, 441,802. Naples is justly regarded as one of the most interesting cities of the world, on account of its classical associations, the magnitude and number of its palaces and public buildings, the picturesque animation of its principal streets, and chiefly on account of the beauty of its situation. The approach to Naples from the sea is famous for its loveliness. There are 5 principal land entrances, but it is an open city like London and New York, provided only at the leading avenues with barriers for the purpose of collecting the *gabella* or duties on provisions. It retains only a few fragments of its mediæval fortifications. Its 8 castles and modernized gates are surrounded by streets and houses, and are now within the city. It is built partly at the base, partly on the slopes of amphitheatre-like hills, divided into two natural crescents by a ridge, which forms the Collina di Capodimonte, Sant' Elmo, and Pizzofalcone, terminating on the S. in a small island occupied by the Castel dell' Ovo, and joined by a causeway to the mainland. The crescent E. of this ridge includes the bulk of the population, the most ancient part of the city, and the principal edifices and public institutions, extending from the heights of the Capodimonte hill and the Sant' Elmo castle to the river Sebeto, and intersected from N. to S. by a long thoroughfare, the lower portion of which forms the famous Strada di Toledo. On a depression between the Capodimonte and Sant' Elmo hills are the suburbs La Sanita and L'Infrascata, and on the slopes of the former the suburbs Dei Miracoli and Le Vergini. The crescent on the W. of Sant' Elmo is the modern city, known as the Chiaia or quay, connected with the E. portion by the streets occupying the depression between Sant' Elmo and Pizzofalcone, and by a broad avenue which bears suc-

cessively the names of Gigante, Santa Lucia, Chiatamone, and Vittoria, and which runs along the shore at the foot of Pizzofalcone from the royal palace on the E. to the public gardens (Villa Reale) on the W. Another broad street, Riviera di Chiaia, passes along the whole length of the Chiaia; and at its W. extremity are the suburbs of Piedigrotta and Mergellina. The length of Naples, from the Sebeto bridge on the E. to the Mergellina suburb on the W., is 4 m.; the breadth, from the Capodimonte hill on the N. to the Castel dell'Ovo on the S., is 2½ m.; the circumference is nearly 11 m. The number of streets is about 1,800, including *strade* (main avenues), *vichi* (cross streets), *ricioletti* (smaller streets), *strettule* (lanes), *calate* (steep streets leading to the old city), *gradoni* (the steepest streets with steps), *salite* (streets running to the suburbs), *rampe* (streets with many branches), a few large thoroughfares called *vie*, and a few *ruos* (sing. *rua*), French names given during the Anjou dynasty. The streets are generally straight, and paved with square blocks of lava; the large thoroughfares are lighted with gas, but only the principal of them have a sidewalk. The majority of the houses are divided into separate tenements, and vie with the streets in the variety of their occupants. They are known under the grandiloquent name of *palazzi*. The ground story consists of a series of arched cells, all of the same shape and size, occupied generally by tradesmen or for cafés or restaurants; and on the upper floors lodge numbers of families. No people of Europe, not even the Parisians, are fonder of outdoor life than the Neapolitans; and it is nothing unusual to see the children washed and dressed, and other domestic scenes of more or less delicate nature enacted in the open street. No other city in the world possesses such a mass of houses of the same description, so densely crowded with all sorts of people, and so grotesquely illustrative of all varieties of occupation and phases of life, as Naples. The Strada di Toledo, the main artery of Naples, was built in the 16th century by Pedro de Toledo, and separates the mediæval Naples from the modern city. It contains the principal shops, which, however, are much inferior in elegance to those of Paris and London. It runs N. and S. for about 1½ m., from the end of the Strada di Santa Lucia, near the royal palace, to the Museo Borbonico, but is hardly 60 feet in width, while it is bordered by houses 5 to 7 stories high. Few of the other streets exceed 30 feet in width, and many are not above 15 to 20 feet, while some are still narrower. The balconies of most of the houses and the booths and stalls give the streets an appearance of being still more contracted than they really are. The Santa Lucia was rebuilt and enlarged in 1826, and contains one of the markets for fish, especially for shell fish and oysters, which are in great demand.—Naples possesses hardly any squares. There are a few public places, or *larghi*, some of which are decorated with

fountains and statuary. The principal of these are the Largo del Mercato, the Largo del Palazzo, and the Largo del Castello. The fashionable promenade is the Villa Reale, which may be said to form part of the Riviera di Chiaia. The lower classes are only admitted to it on the festival of Santa Maria di Piedigrotta. It is 5,000 feet long and 200 wide, and planted chiefly with evergreens, oaks, and acacias. It was first laid out in 1780, enlarged in 1807, and about ¼ of it was added in 1834. The early part of it is in the Italian style, and the additions are imitations of English landscape gardening, and contain two temples dedicated to Virgil and Tasso, winding paths, grottoes, and a *loggia* toward the sea, from which the gardens are separated by a wall and parapet. The sea air proved so injurious to the statuary, that the famous Toro Farnese was removed to the Museo Borbonico, and replaced in 1825 by the large granite basin which forms the central fountain. Other remarkable statues have also since been taken away, and replaced by rather mediocre copies of some of the most celebrated works of antiquity. The Molo is to the masses of the people what the Villa Reale is to the *beau monde* of Naples. It is described as "an epitome of the town, which exhibits most of its humors. Here stands an enthusiastic friar, preaching to one row of *lazzaroni*; there Punch, the representative of the nation, holds forth to a crowd. Yonder another orator recounts the miracles performed by a consecrated wax work. Beyond him are quacks in hussar uniforms, exalting their drugs and brandishing their sabres as if not content with one mode of killing. The next *professore* is a dog of knowledge, great in his own little circle of admirers. Opposite to him stand two jocund old men, in the centre of an oval group, singing alternately to their crazy guitars. Further on is a motley audience, seated on planks, and listening to a tragi-comic *filosofo*, who reads, sings, and gesticulates old Gothic tales of Orlando and his paladins." More recently, however, these popular minstrels, or *cantatori*, have removed to the shore of the Marinella beyond the Molo Piccolo, where they continue to delight their motley audiences, who are mostly standing or seated on planks. The Marinella, a long open beach, and the Largo del Mercato, were once the principal places of resort of the *lazzaroni*, formerly a very troublesome and distinct class of people, but now subjected to the same regulations as the other citizens, and possessing among their ranks the most industrious boatmen and fishermen of the city, though they still preserve their fondness for lying on the beach and basking in the sun. Within the present century they have been notorious as the petted children of tyranny; but during the recent triumphs of Garibaldi they have exhibited the same patriotic enthusiasm which distinguished them in the times of the fisherman Masaniello, whose revolt was chiefly due to their influence. (See LAZZARONI.) Offshoots of the *lazzaroni*, and

now among the most mischievous population of Naples, are the so called *Camorre* and *Guappi*, who were very troublesome during the recent entrance of the Garibaldian troops.—Prominent among the public buildings of Naples are the castles. The Castel Nuovo, with its massive towers and fosses, is situated near the port. It has been compared to the tower of London. The triumphal arch, erected in honor of the entry of Alfonso of Aragon into the city in the 15th century, is remarkable for its classical style, and stands between two of the old broad and massive Anjou towers. Beyond the celebrated bronze gates are the barracks and a magnificent hall, now used as an armory (*sala delle armi*, or *sala di San Luigi*), containing 60,000 stand of arms, and formerly used for a royal reception room, for state festivals, and for various other purposes of the court or of public entertainments. Adjoining the castle and the royal palace are the dockyard and arsenal. The Castel dell' Ovo, in the southernmost part of the city, is of oval form, as indicated by its name, and defended by bastions and outworks. It was much enlarged by Charles I. The Castel Sant' Elmo, the most commanding point in the city, was built in its present form by Pedro de Toledo, and is said to abound with mines and subterranean passages, which, together with the counterscarp and fosses cut in the solid tufa, and its formidable walls, make it of great strategical importance, though it has lost some of its reputation for military strength. The Castel Capuano was once the residence of the Swabian and occasionally of the Anjou dynasty; it is now the seat of the tribunal of commerce, and of the principal courts of criminal and civil law, and contains a prison on the ground floor. The Castel del Carmine was fortified after the revolt of Masaniello, when it was the stronghold of the insurgents, and is now used as a military prison and barracks. The principal market place of Naples was the scene of Masaniello's insurrection. The chief aqueduct, which supplies the city fountains with water, is the Acqua di Carmignani. The Acqua della Bolla supplies the lower quarters of the city. The Acqua del Leone furnishes the purest water. There are two sulphur springs in the city of great celebrity.—The number of churches is over 800. The most important is the cathedral, which retains little of its original Gothic character excepting in the towers. It was commenced at the end of the 13th and completed at the beginning of the 14th century. The façade, destroyed by an earthquake in the middle of the 14th century, was rebuilt about 1407, and received its present modern form in 1788. Over the great entrance are the tombs of Charles I. of Anjou, Charles Martel, and his wife Clementia of Hapsburg. It also contains the tombs of King Andrew of Hungary, of Pope Innocent IV., and of other noted personages. Among the celebrated chapels of the cathedral is the Capella de' Minutoli, the scene of one of Boc-

caccio's stories, and containing the tomb of the founder, Archbishop Minutoli, which, like many other monuments in the church, is due to the genius of Bamboccio. Opposite to the entrance of the basilica of Santa Restituta, once the place of worship for the Greek ritual and now forming part of the cathedral, is the Cappella del Tesoro, or the chapel of San Gennaro (St. Januarius), with the two celebrated vials said to contain the blood of that saint, the liquefaction of which gives occasion for the greatest religious festivals of Naples. (See JANUARIUS, SAINT.) The "Tomb of San Gennaro," with the sick waiting to be cured, and several other paintings and frescoes in the chapel, are by Domenichino. The tomb of San Gennaro is under the high altar in the richly ornamented subterranean chapel called the "confessional of San Gennaro," near the kneeling statue of Cardinal Carafa, which is said to have been executed by Michel Angelo. The church of San Aniello a Capo Napoli, or San Agnello Maggiore, in the Largo San Agnello, has a painting of San Carlo by Caracciolo, said to be one of the most masterly imitations of Annibale Carracci. Beneath the richly decorated church of Santi Apostoli, said to have been founded by Constantine on the ruins of a temple of Mercury, and rebuilt with greater magnificence, is a cemetery containing the tomb of the poet Marini. Among the other churches are Santa Chiara, with a Latin inscription over the Gothic tomb of King Robert the Wise, attributed to Petrarch, designed like many other monuments by Masuccio II.; San Domenico Maggiore, rich in mediæval works of art; San Filippo Neri, one of the finest churches in Naples; San Lorenzo, associated with one of the stories of Boccaccio, with Petrarch, who resided for some time in the cloister attached to it, and with Alfonso I., who in the chapter house of this church proclaimed his natural son Ferdinand heir to the throne by the title of duke of Calabria. San Martino is celebrated for the magnificence of the view from it, and of its architecture and works of art. Santa Maria del Parto, in the Mergellina suburb, called by the common people *il diavolo di Mergellina*, derives its name from Sannazzaro's *De Partu Virginis*, and contains that poet's tomb.—Mendicity is prohibited by law in Naples, but there are no poor rates, and beggars abound. About 60 institutions are devoted to charitable purposes. The most celebrated of them is the *albergo de poveri* or *reclusorio*, an immense institution, which with its dependencies accommodates upward of 5,000 persons. It is 1,050 feet long, but was intended by its founder Charles III. to cover a still larger ground, to serve as an asylum and an educational establishment for all the poor of the kingdom. To some extent it is made to answer this purpose; boys and girls are educated there and brought up to trades, and the boys generally enlist in the army. The greatest among the other hospitals is the *santa casa degl' incurabili*, or hospital for incurable dis-

eases, but open to the sick of all descriptions; it is in high repute as a medical school, and accommodates about 2,000 patients. The hospital Della Annunziata is chiefly intended for the reception of foundlings. There are annually about 2,000 foundlings out of 15,000 births, and they are better cared for in Naples than in other parts of Italy.—Prominent among the educational institutions is the university, which contains 54 different professorships and about 1,500 students. The Chinese college, founded by Father Ripa, a missionary in China, is intended for the training of young Chinese, who, after having completed their education, are employed as missionaries in their native country. The college of music, in which Bellini was educated, enjoys a high reputation, and has for its present director Mercadante. It gives free instruction to 100 pupils, and admits others at a small remuneration. The national school of medicine and surgery is attended by upward of 100 students, contains a pathological museum, and communicates by a subterranean passage with the practical medical school at the hospital for incurables, in which place the academy of medical and surgical science holds its sittings. The *società reale Borbonica* comprises academies of science, of archæology, and of the fine arts, and the two former publish their transactions. There is also an academy for naturalists (*accademia degli aspiranti naturalisti*); and the *accademia Pontaniana* is devoted to letters as well as to science. The observatory of Naples, situated on the Capodimonte hill, about 500 feet above the level of the sea, is an elegant building, completed in 1820, after the plans of Piazza, under whose direction it has achieved great celebrity, and who has been succeeded by Gasparis. The botanic garden, completed in 1818, is under the direction of Professor Tenore, and chiefly remarkable for its collection of trees. Naples possesses 4 great public libraries, the Borbonica, the Brancacciana, the university library, and the Girolomini; beside which there are a great number of private libraries.—The greatest glory of Naples, however, is the Museo Borbonico, situated in a building originally intended for the cavalry barrack, and afterward remodelled from the designs of Fontana for the use of the university, and for some time the seat of the academy of science. It is still called *palazzo degli studii pubblici*, or simply *studii*. The name *museo reale Borbonico* was given to it by Ferdinand I., who, after its enlargement in 1790 for the purpose of receiving the royal collection of art, caused all the antiquities and pictures in the royal palaces of Portici and Capodimonte to be brought into it in 1820. The museum consists of 16 collections, comprising on the ground floor ancient frescoes, mosaics, and mural inscriptions, Egyptian antiquities, ancient sculptures, inscriptions, the Toro Farnese, and bronzes; on the staircase, ancient glasses, pottery, cinque-cento objects, and re-

served cabinet; upstairs, the papyri, gems, medals and coins, small bronzes, vases, paintings, and the library. The collection of ancient frescoes contains more than 1,600 specimens found at Herculaneum and Pompeii, and is constantly increased by the result of ceaseless excavations. The collection of ancient sculpture is one of the most interesting of the museum, particularly the portico with the statues of the Roman emperors, that of Agrippina being considered by Winckelmann superior to those of the Villa Albani or the capitol, and the colossal bust of Julius Cæsar in Carrara marble being regarded by Visconti as the finest representation known of him. In the hall of Flora is the Flora Farnese, one of the masterpieces of ancient sculpture. In the hall of the Muses is the famous vase of Greek marble, which was found in the bay of Gaëta among the ruins of ancient Formiæ, and which is covered with bass-reliefs representing the birth of Bacchus, by the Athenian sculptor Salpion. One of the most unique works in the hall of Adonis is the "Hermaphrodite Faun" in Parian marble, found in the ruins of Pompeii. The greatest work in the hall of Jupiter is the Torso Farnese, or the Torso of Bacchus, from the Farnese collection, hardly inferior in beauty to the Torso Belvedere, and attributed by some authorities to Phidias. A fragment of Psyche, found in the amphitheatre of Capua, and supposed to be the work of Praxiteles, is regarded as the most exquisite representation of that subject extant; and in the same hall is a bass-relief representing Bacchus intoxicated, which is regarded by Winckelmann as the finest bass-relief of Grecian art. The hall of Atlas contains statues and busts of Homer, Socrates, Solon (one of the most admired in the collection), Demosthenes, Herodotus, Cicero, and other illustrious men. The hall of Tiberius contains the bust of Seneca, known as the Farnese Seneca, and a Vestal, known under the name of the Zingarella; and among the most remarkable works of art there is the quadrangular pedestal of Greek marble erected in honor of Tiberius by 14 cities of Asia Minor, which he had rebuilt after their destruction by an earthquake. The cabinet of the Venus Callipyge has for its principal ornament the statue of that goddess, found in the golden house of Nero, and which passed for a long time as one of the Venuses executed by Praxiteles. The collection of inscriptions, or the *museo epigrafico*, possesses about 1,200 inscribed monuments from Cumæ, Herculaneum, Pompeii, Stabia, Baia, and other ancient localities near Naples. This part of the museum also contains the group of the Toro Farnese, regarded by Pliny as one of the most remarkable works of antiquity. The Farnese Hercules, executed by the Greek sculptor Glycon, and highly popular among the ancients as the Hercules of Glycon, belongs to the other noticeable works of this collection. It was found in 1540 among the ruins of the baths of Caracalla, by Pope Paul III., who employed Michel

Angelo to supply the missing legs, which were executed by Guglielmo della Porta, a sculptor of Milan, from Angelo's model in terra cotta. The original legs have since been found and restored to the statue. The gallery of bronzes is the most extensive collection of the kind. Among its principal treasures of art is the finest bronze statue in the world, representing Mercury in repose, found in Herculaneum; and the most graceful of the bronzes found in Pompeii represents the dancing faun. Among the finest busts there are those of Berenice, of Scipio Africanus, and of Seneca. Almost all the works in this collection are from Herculaneum and Pompeii. The collection of ancient glass includes nearly every article into which glass can be worked, and contains about 4,000 specimens, including the window glass found in the villa of Diomed at Pompeii. The most beautiful of the vases there was found in 1837, full of human ashes, in the tomb attached to the house of the mosaic columns at Pompeii, and has been often compared to the Portland vase. The collection of terra cottas contains more than 5,000 articles of ancient Roman pottery, including the Volscian bass-reliefs found at Velletri, and 3 *tasse* of great beauty, one of them adorned with the bust of a matron, and bearing the inscription: *Bibe amice de meo*. The cinque-cento collection contains pictures brought from India and miscellaneous objects from the South sea islands, and a large number of sacramental vessels. Among its most distinguished articles are a sacramental pix in bronze, said to have been designed by Michel Angelo, a bronze bust of Dante, and a superb silver chest (the *cassetta Farnese*), with rock crystal and bass-reliefs illustrative of mythological subjects and of events in the life of Alexander the Great. The "reserved cabinet" contains works of art which are not considered appropriate for public inspection, and can be seen only by special permission from the government. Alexandre Dumas, immediately after his appointment by Garibaldi in 1860 as director of the museum, and during his brief tenure of this office, is said to have caused this room to be thrown open to the public. The "room of the papyri" includes the contents of one of the most remarkable discoveries at Herculaneum—a library with more than 1,700 rolls of writings, some of which were on first sight destroyed by the workmen employed in the excavation as mere pieces of charcoal. Paderni was the first to discover that the supposed sticks of charcoal were nothing less than MSS. disfigured by the effects of the fire. After various experiments, a machine was invented by Father Piaggi for unrolling the papyri, which has not yet been supplanted by a more effective method of operation, although Sir Humphry Davy endeavored to find one by the resources of chemistry. The bulk of the library seems to have been composed of dissertations on the Epicurean philosophy. Nearly

one third of the papyri have been unrolled and deciphered. The cabinet of gems contains the collection of cameos and intaglios, consisting of 1,600 specimens, the famous *tazza Farnese*, nearly a foot in diameter, and numerous curious and precious articles (*oggetti preziosi*) of gold and silver, almost all found in Herculaneum and Pompeii. In the collection of medals are about 40,000 coins of Magna Græcia, and Sicilian and mediæval coins. The museum of small bronzes contains, among a great variety of articles suggestive of the domestic life of the inhabitants of Pompeii and Herculaneum, a very beautiful candelabrum 8 feet high, a room filled with sacrificial vessels, surgical and musical instruments, and the renowned Heracleian tables, found in the 18th century near the site of ancient Heracleia. The mosaic pavements in this section of the museum are of peculiar interest. The collection of sepulchral vases comprises upward of 8,000 specimens, the most beautiful of which are the three found at Nola, consisting of the vase of Cassandra, the Bacchanalian vase, and the "Burning of Troy," with the principal incidents of the Iliad, which is the finest of them all. The gallery of paintings comprises about 900 works of Italian and foreign artists, and the private collection of the prince of Salerno. Among the masterpieces (gallery of *capi d'opera*) are Bassano's "Raising of Lazarus;" Annibale Carracci's *Pieta*; Claude Lorraine's "Egerian Landscape;" Correggio's "Marriage of St. Catharine;" Domenichino's "Guardian Angel;" Albert Dürer's "Nativity;" Raphael's "Holy Family" (*Madonna col divino amore*); Giulio Romano's "Holy Family" (*Madonna della gatta*); Titian's celebrated "Magdalen in Prayer," and the same artist's masterly portrait of Philip II; a copy of the "Last Judgment," by Marcello Venusti, executed in the Sistine chapel under the direction of Michel Angelo himself, who presented it to Cardinal Farnese; and pictures by Andrea del Sarto, Zingaro, and other eminent artists; copies of Correggio by Annibale Carracci; and a most remarkable and touching picture called the *Madonna del coniglio* from the rabbit introduced into it, or the *Zingarella* (gypsy) from the turban worn by the Virgin during the flight out of Egypt. The gallery contains, among a great number of inferior works, several fine productions of Byzantine, Neapolitan and various other Italian schools, including Raphael's two cartoons of Moses on Mt. Sinai and the holy family; Titian's nude figure of Danaë; Salvator Rosa's "Christ disputing in the Temple;" Roderigo's (Il Siciliano) masterpiece representing "St. John the Baptist and St. Francis contemplating the Trinity;" Andrea di Salerno's crowning work of the "Adoration of the Magi;" Bernardo Gatti's "Crucifixion;" Matteo Giovanni da Siena's "Massacre of the Innocents;" Rembrandt's portrait of himself; Vandyke's portraits of the princess of Egmont, of a magistrate, and of an unknown man; Van

Eyck's "Village Festival;" Wouverman's "Bivouac on the Banks of a River;" and other works by Dutch and Flemish masters. In the prince of Salerno's private collection are a number of works by celebrated artists. The royal palace contains Raphael's "Madonna and Child," and other valuable works of art. It was partly destroyed by fire in 1837, and has since been enlarged and repaired by the late King Ferdinand. The altar of its chapel is remarkable for precious marbles and for Fancesca's statue of the conception. The suburban villa of the ex-king of Naples (*palazzo reale di Capodimonte*) contains a gallery of modern pictures, chiefly by Neapolitan artists.—The private palaces of Naples are far inferior in architectural beauty to those of Florence and other cities of upper Italy, but almost all of them contain museums of works of art. The most beautiful private palace is the Palazzo Gravina, in the Strada di Monte Oliveto, built at the end of the 15th century by Ferdinando Orsini, duke of Gravina, after the design of Gabriele d'Agnelo, and now the property of the government, and used as the general post office. The *palazzo dei ministri*, called also San Giacomo, from its being on the site of the ancient monastery of that name, between the Strada di Toledo and the Largo del Castello, was begun in 1819 and completed in 1825 for the purpose of conducting all the public business in one and the same building. It may be compared to the offices of Downing street in London brought under one roof, and contains 6 courts, 846 apartments, and 40 corridors, covering not less than 5 acres of ground. The Palazzo Pianura, near the church of San Paolo, was the residence of the poet Marini. The Palazzo Santangelo is remarkable for its fine statuary and collection of coins and medals, illustrative of the numismatic history of the Two Sicilies. The Palazzo Monticelli, a fine specimen of the domestic architecture of the 15th century, was long the residence of the mineralogist Monticelli, whose collection of Vesuvian productions was purchased by the university after his death. The Palazzo Cellammare, now the property of the duke of that name, is surrounded with extensive pleasure grounds. The Palazzo Carafa is now partly converted into barracks and partly occupied by the royal topographical office. The Palazzo Calabritto is now the residence of the British consul and the place of worship for the members of the church of England. Among the other private palaces, the Palazzo Caranico is regarded by some authorities as the masterpiece of the architect Fuga; and the Palazzo Bisignano, in the Strada Costantinopoli, still bears the traces of its original magnificence. Naples abounds with fine villas, as the Villa Regina Isabella on the Capodimonte hill, and the Villa Angri on the Posilippo hill, with superb views on the bay; the villas Belvedere, Floridiana, and Ricciardi, or Villa de' Camaldoli, on the Vomero; and the Villa Ruf-

fo, near the castle of Sant' Elmo, noted as having been the residence of Cardinal Ruffo during Nelson's career in Naples. In the immediate environs of Naples are the Grotta di Pozzuoli or di Posilippo, consisting of a tunnel about 2,250 feet long and 21½ feet wide, excavated in the older volcanic tufa, and containing near the top of the entrance the celebrated Roman columbarium known as the tomb of Virgil. The environs abound with many other remarkable sights, interesting to the classical scholar, archæologist, and naturalist, as well as to the admirers of the beautiful and picturesque in nature, the vicinity of Vesuvius and other volcanic localities presenting scenes of matchless grandeur.—The principal places of amusement are the theatres. The San Carlo, adjoining the royal palace, is the largest Italian opera house in the world. It was designed, by order of Charles III., by Medrano, a Sicilian artist, built in the short space of 8 months by Angelo Carasale, a Neapolitan architect, and opened in 1737. It was burned down in 1816, but rebuilt after 7 months, without altering the original form. It has 6 tiers of boxes of 32 each, and the pit accommodates more than 1,000 persons. It is opened on alternate nights with the *teatro del fondo* in the Strada Molo, which is under the same management as the San Carlo, and likewise exclusively devoted to operas and ballets. The oldest theatre in Naples is the *teatro de' Fiorentini*, now the popular stage of the Italian drama. The opera buffa is represented chiefly in the *teatro nuovo*. The *teatro della Fenice* is devoted both to opera buffa and melodrama. The *teatro Partenope* is a popular theatre, in which farce and comedy are performed twice a day in the Neapolitan dialect. The most characteristic and amusing theatre of them all is that of San Carlino in the Largo del Castello. This is the home of Pulcinello, or of the Neapolitan clown. The performances take place in the morning and evening in the Neapolitan dialect, and are attended by all classes of the population.—The Neapolitans, like the ancient Grecians, combine their devotion with pleasure; and the great popular religious festivals, as the *festa di Piedigrotta* on Sept. 8, and the *festa di Monte Vergine* on Whit-Sunday, both in honor of the Holy Virgin, are scenes of great rejoicing as well as compunction. At the latter place, which is near Avellino at the shrine of the Madonna di Monte Vergine, the inhabitants of Naples meet pilgrims from every part of the country. On the road they beguile the time in dancing the Tarantella and singing national songs; and a great number, who cannot go so far as Monte Vergine, make the pilgrimage to the Madonna dell' Aro, which is 7 m. from the city, at the foot of Mount Somma. Beside the two festivals in honor of San Gennaro, the *festa di S. Antonio Abbate* is celebrated on Jan 17, and continued on every succeeding Sunday until Lent, for the blessing of the animals; and Easter, Ascension day, and the festival of

Corpus Christi also give rise to solemn processions and imposing ceremonies. From Christmas to Feb. 2, the day of the purification, the leading churches and some private families exhibit *presepi* or representations of the nativity. The mountain minstrels from the Abruzzi (*sampognantori*), with their bagpipes, brown cloaks, pointed hats, and sandals, come to Naples at the Christmas season to perform hymns and carols beneath the figures of the Virgin, and enhance the picturesque appearance which the city presents at that season. No other people in Europe are so fond of pleasure, and at the same time so devoted to their religious usages, as the Neapolitans. An English writer says of the general characteristics of the people and of Neapolitan life: "Even the lowest class enjoy every blessing that can make the animal happy—a delicious climate, high spirits, a facility of satisfying every appetite, and a conscience which gives no pain. Here tatters are not misery, for the climate requires little covering; filth is not misery to them that are born to it, and a few fingerings of macaroni can wind up the rattling machine for the day. . . . The people seem in general peaceful and contented, unconscious of want at least; they consume little, and that little is cheap. For 8 grains a day (8 cents), a man has his fill of macaroni; and for 3 grains more he may have his *frittata* (very good fish, or vegetables fried in oil) at any of the innumerable stands of itinerant cooks about the streets, which is not the only luxury of the gastronomic kind within his reach. A glass of ice water costs 1 grain, and if properly seasoned with grape juice and sugar, 2 grains. The price of these things is kept down by government, ice or hardened snow being abundantly supplied at the public expense from natural ice houses in certain cavernous rocks above Stabia and Sorrento, and even on Vesuvius. The ice in baskets is made to slide down the mountain, along light ropes into boats, which sail across the bay during the night and land their precarious cargoes before day. The lower people have clubs, where they assemble 20 or 30 together and contribute each one grain for wine for an evening. The nobility are numerous, and delight in splendor and display, although their means are very limited. Titles are here so common that you find at every corner *principi* without a virtue or a ducat. The fondness for the use of carriages is great. Women at all above the lower ranks do not walk; those who cannot afford a carriage are doomed by pride to perpetual imprisonment in their own houses, or only go to church with one or two poor devils hired for the occasion, who put on antiquated livery and carry a book or a cushion. The roofs of the houses, which are flat and adorned with flowers and shrubs in boxes, afford air and exercise to the women. Thus living in idle retirement, their mind is exclusively bent on the means of procuring a lover, and the tales of

Boccaccio convey a likeness of their moral habits and manners."—The number of the city clergy in 1860 is 6,341; they are generally poor. The scholars and savants, artists, jurists, medical men, and the higher middle and professional classes of Naples generally, constitute a very intelligent and refined society; and its men of science and scholars are celebrated in Italy for their devotion to their respective branches of study. The number of strangers, chiefly from England, is great at all times, but particularly during the winter, notwithstanding the frequently dangerous effect of the climate upon foreign constitutions, especially upon consumptive patients.—Naples has 3 ports: the Porto Piccolo, the last remains of the ancient port of Palæopolis, and now only suited to small craft; the Porto Militare, a new harbor with a depth of water of 5 fathoms, bounded N. by the Porto Grande and S. by a mole, which runs in a S. E. direction into the sea for a distance of 1,200 feet; and the Porto Grande, the principal port, but with only 8 or 4 fathoms in its deepest part, having suffered from the silting of the sand and shingle. Between the Porto Grande and Porto Piccolo is the *inma colatella*, with the offices of a branch of the board of health and the captain of the port. On the other side of the Porto Piccolo is the custom house. The Mandracchio district, on the S. E. of this latter port, is inhabited by the dregs of the Neapolitan population, resembling in their want of education the poor people who cluster round some of the back alleys and lanes of the streets near the Thames in London.—The principal imports of Naples are sugar, coffee, and other colonial produce; coal, salted fish, cotton, woollen, silk, and flax goods; iron, tinware, hardware, and a great number of miscellaneous articles. The chief exports are oil, grain, silk, almonds and dried fruits, hemp and flax, madder, wool, cream of tartar, and liquorice. The movements of shipping in 1855 were as follows:

Countries.	Entrant. vessels.	Clearance. tonnage.
Austria.....	17	3,510
Belgium.....	14	2,530
France:		
sailing vessels, 142, tonnage 34,045	584	158,939
steamers, 892, " 129,387		
Great Britain:		
sailing vessels, 295, " 64,314	454	122,773
steamers, 159, " 53,458		
Holland.....	44	8,489
Naples, kingdom of:		
sailing vessels, 4,354, tonnage 895,335	5,172	970,504
steamers, 218, " 75,179		
Norway.....	9	1,773
Papal States:		
sailing vessels, 706, tonnage 89,156	641	55,101
steamers, 185, " 15,945		
Sardinia:		
sailing vessels, 130, " 11,434	408	120,371
steamers, 273, " 109,487

Tuscany.....	95	10,224
United States.....	19	5,971
Total.....	7,718	1,482,667

showing an increase of 1,602 vessels and 862,353 tons over 1854. In 1856, however, the shipping declined to 7,435, tonnage 1,118,524 (including 4,909, tonnage 410,196, in the coasting trade); and in 1857 it fell to 4,892, tonnage 685,075 (France 617, Great Britain 381, Sardinia 296, other countries 618, and coasting trade 2,982 vessels). The principal merchants of Naples are all more or less engaged in the banking business. At the head of the bankers stands the house of the Rothschilds, one of whose original branch establishments was founded at Naples under the direction of the late Baron Charles. The bank of the Two Sicilies is the government bank, guaranteed by the possession of landed property, and chiefly intended, like the bank of Hamburg, for receipts on deposit and not for the issue of notes on credit. There is also a discount office at Naples under the auspices of the government. Merchants are arranged by the chamber of commerce into 6 different classes, and credit to a certain amount at the custom house for the payment of duties is granted to them accordingly. Ship building is carried on to some extent. The anchovy and tunny fisheries are in active operation. Naples possesses iron and glass works and royal type foundries; and the principal other manufactures are macaroni, silks, embroideries, carpets, broadcloth, chemicals, soaps, perfumery, artificial flowers, corals, china, hats, carriages, gloves, &c.—For municipal purposes the city is divided into 12 districts, viz.: Mercato, Pendino, Porto, San Lorenzo, and Vicaria, the most populous, in the old or E. part of the city; San Ferdinando, in the central part; Chiaia and San Giuseppe, in the W. end; San Carlo all' Arena, in the N. part; Stella, Avvocata, and Monte Calvaria, in the upper part on the Capodimonte and Sant' Elmo hills. Every district has a commissary of police, and the number of military posts is 66, beside extensive barracks for infantry and cavalry. Naples is the seat of the general government, including a sanitary and educational department and one for the superintendence of the national archives, an immense collection of historical, municipal, judicial, and financial documents. Beside a prison for debtors, there are 5 prisons in Naples, the alleged abuses in which were stated by Mr. Gladstone in 1851 in his letter to the earl of Aberdeen, particularly referring to the sufferings of Baron Piorio and other political prisoners.—The principal antiquities of Naples are the catacombs, which are of greater extent than those of Rome. (See CATACOMBS, vol. iv. p. 285.) The environs abound with other celebrated relics of antiquity, but in the city proper there are not many of them, excepting the fragments of the temple of Castor and Pollux, of the Julian aqueduct, now called Ponti Rossi, and a few other remains. The greatest authority on Neapolitan inscriptions is Mommsen's *Corpus Inscriptionum Neapolitanarum* (Leipsic, 1851).—Several of the learned Neapolitan antiquaries

claim for Naples a Phœnician origin, but it is generally considered to have been originally a Greek city and colony of Cumæ, although the account of its first foundation, under the name of Parthenope, is regarded by many authorities as a mythical tradition. According to several accounts the city was, after its increase through settlers from various parts of Greece, divided into an old town (Palæopolis) and a new town (Neapolis). But the identity of the connection between the two names is not yet clearly established. Niebuhr places the situation of Palæopolis near the site of the present town of Pozzuoli, and Livy refers to them as close to each other; but long before his time (330 B. C.) Palæopolis is mentioned as having been engaged in hostilities with Rome, and the name seems soon afterward to have disappeared from history, and to have become merged in Neapolis, which early became a faithful ally and dependency of Rome, and noted for the courage of its citizens from their successful resistance to the attack of Pyrrhus in 280 B. C., while the strength of its fortifications caused Hannibal to leave the place unmolested during the second Punic war. It retained to a far greater extent than other Italian cities its Greek culture and institutions, and many of the higher classes of Romans resorted to Neapolis for their education, on account of the beauty of the climate and the scenery, and of its hot springs. It recovered quickly from the calamities of the civil war of Marius and Sylla (82 B. C.). Under the empire it continued to be a favorite resort of the Roman nobility. Nero made his first public appearance as an actor on the stage of Naples, and the voluptuous character of the city caused it to be called by Ovid *in otia natam Parthenopen*. The celebrated villa of Vedius Pollio and other villas lined the coast on both sides of the city. The great tunnel under the still existing Monte Posilippo was then as now an object of admiration. The chief glory of the city was its association with Virgil, who is supposed to have resided there for a considerable period, and whose tomb is said to have been still extant there in the times of Statius and Silius Italicus; which latter poet also died in Neapolis, while the former resided there and speaks of the city as his birthplace. After the fall of the empire it escaped the ravages of the Vandals; and though conquered by Theodoric (A. D. 493), it seems to have retained its prosperity under this Gothic king. In 536 it was taken after a protracted siege by Belisarius, and besieged and retaken by Totila (542), but recovered by Narses in 553. In 572 it was constituted a separate duchy, forming a dependency of the exarchate of Ravenna. In the beginning of the 8th century it threw off its allegiance to the Byzantine emperors, and for about 400 years enjoyed an independent government under dukes of its own election, though often engaged in hostilities with the Lombard dukes of Benevento, to whom it was obliged to pay tribute. When the duchy of Benevento was

divided into 8 principalities, the prince of Capua endeavored to gain the supremacy, and succeeded in seizing Naples (1027); but Duke Sergio, aided by a band of Normans, compelled him to evacuate it a few years afterward. The Normans were then encouraged to settle in the vicinity of the city, and eventually, after having conquered the whole of south Italy and Sicily, they reduced Naples after a protracted siege; and the city, which was the last to be subdued by the Normans, acknowledged Roger I. of Sicily as its sovereign (about 1187). On the extinction of the Norman dynasty Naples became subject to the house of Swabia from 1198 to 1268; and under the Anjou dynasty Naples superseded Palermo as the seat of the government. In 1442 the last king of the Anjou dynasty was conquered by Alfonso of Aragon. Under the Aragonese and Spanish kings it was ruled by viceroys till the peace of Utrecht, when it was annexed to the possessions of the house of Hapsburg. Carlo, son of Philip IV. of Spain, became master of the city and kingdom in 1785, and founded the dynasty which, except during the period of the French supremacy and the reign of Murat, occupied the throne until Sept. 7, 1860, when Naples was taken possession of by Garibaldi in behalf of the king of Sardinia. The king of Naples, Francis II., had previously fled from the city; and Victor Emanuel, king of Sardinia, made his entrance into it on Nov. 7. Naples has been often alarmed by earthquakes, and more recently in 1857 and 1858; but, although the surrounding country was laid waste, the city itself was not injured.

NAPOLEON BONAPARTE. See **BONAPARTE**.

NARBONNE, a city of France, in the department of Aude, near the coast of the Mediterranean, with which it is connected by a canal, 83 m. E. from Carcassonne, and 54 m. S. W. from Montpellier; pop. in 1856, 12,742. The most remarkable edifices are the cathedral of St. Just, a handsome Gothic structure founded in the 13th century, the church of St. Paul, an ancient building in the Romanesque style, and the archiepiscopal palace. Manufactures and trade are flourishing. The ancient Narbo Martius was founded by the Romans in 118 B. C. Many of the soldiers of Cæsar's tenth legion having been settled there, it was thence frequently called Decumanorum Colonia. It was taken by the Saracens in 719, and held by them for nearly half a century. In the middle ages it was one of the most flourishing towns in France. Hardly any remains of the Roman period now exist. Varro Atacinus, the Latin poet, and the Roman emperor Aurelius Carus, were natives of Narbonne.

NARBONNE-LARA, Louis, comte de, a French soldier and statesman, born in Colorno, in the duchy of Parma, in Aug. 1755, died in Torgau, Germany, Nov. 17, 1818. His father was gentleman of the bedchamber and his mother lady of honor to the duchess of

Parma, daughter of Louis XV. On the death of the duchess in 1760, his mother became attached in the same capacity to Mme. Adelaide at the French court, and the son was educated with the royal princes. He entered the military service, became a colonel in 1785, and was employed for some time in the ministry of foreign affairs under Vergennes. In 1789 he favored the new opinions, and became very popular in the department of Doubs, where in 1790 he was placed in command of the national guard; but he was always loyal to the royal family. He accompanied the king's aunts when they left Versailles in 1791, and, after seeing them safe out of France, returned to Paris. Through the influence of Mme. de Staël, with whom he had an intimate friendship, he was appointed minister of war, Dec. 6, 1791, but was dismissed in March, 1792, and joined the army. After the attack on the Tuileries, Aug. 10, 1792, when he was present in the capital and displayed great courage, he fled to London, where he wrote a memoir to the convention in behalf of Louis XVI. He returned to France in 1800, was restored to his rank as general of division in 1809, and was governor at Raab and Trieste, and minister plenipotentiary at the court of Bavaria. He accompanied Napoleon as special aide-de-camp to Russia, was ambassador to Vienna in 1813, minister to the congress at Prague, and finally military commander at Torgau.

NARCISSUS (Gr. *ναρκη*, torpor), the name of a genus of beautiful flowering plants of the natural order *amaryllidaceæ* (R. Brown), used at funerals among the ancients for the lethargic effects of their fumes. The narcissi have truncated bulbs, linear leaves, which are either flat or channelled, a naked, often compressed or angular scape surmounted by a one-leaved bract or spathe, which bursts open on one side and shows one, two, or more white or yellow flowers, each supported by a pedicel. The flower is composed of a perigone consisting of 6 petaloid, lanceolate, or oval segments united at base, and 6 stamens of unequal length, those which are opposite the sepals being the longest, and all surrounded by a sort of cup (*corona*), usually of a different color and varying greatly in length and proportion in different species. According to the Linnæan idea, this cup is the nectary; but, as has been shown by Robert Brown, who has studied the morphological characters of the order, it is no more than a modification of another series of stamens by the expansion of the filaments, which cohere at their edges. The ovary is usually compressed, and is surmounted by a simple style.—The species of narcissus are numerous, and are much esteemed for the garden, giving it a cheerful appearance in early spring. The daffodil (*N. pseudonarcissus*, Linn.), which grows spontaneously on the high pastures of the range of the Jura mountains in Europe in immense quantities, also occurs in Great Britain, and is considered one of the most beautiful native

plants of that kingdom. There is a variety with double flowers in our gardens, and sometimes employed for edging to flower borders, or else planted in clumps in some warm and sunny bank, where its large, showy blossoms exhibit themselves in April. The true daffodil of the poets is *N. poeticus*, found wild in Europe and in Great Britain, abundant especially in many places at the foot of the Jura range, and seen in most old gardens. The edge of the cup is beautifully bordered with a narrow crimson line. Its perfume is pleasant, especially in the double-flowered variety, where the cup and stamens are obliterated in the multiplication of the other organs. The two-flowered narcissus (*N. biflorus*, Curtis) resembles this, but the cup has no tinted line, and the two flowers from the same spathe are a normal characteristic. There is a curious species known as "butter and eggs" (*N. incomparabilis*), having both yellow and white petals, which in the double-flowered variety naturally suggest the trivial name. This is sometimes called the orange phoenix in the Dutch flower catalogues. A still more remarkable species is the hoop petticoat (*N. bulbocodium*), where the cup is very much expanded and stands widely inflated beyond the petals. The jonquil narcissus (*N. jonquilla*, Linn.) is a pretty species with yellow blossoms, sweet-scented, and with foliage looking like that of the rush (*juncus*), whence the specific name. The polyanthus narcissuses of the flower catalogues are beautiful varieties of the *N. tazetta* (lt. *tazza*, cup, the corona being regularly cup-shaped). The style of this species is large and conspicuous, the scape is strong and tall, and from the spathe 6 to 10 flowers issue. Those known as the *grand monarque* and the *grand primo* have white blossoms with citron-colored cups; the *soleil d'or* has yellow and orange flowers, the *staaten general* yellow; and the double Roman with double cups is in much esteem.—The culture of the narcissi is simple, requiring a good and deep soil, and the removal of the offsets from the bulbs by occasionally taking them up and transplanting afresh in the autumn. Some of the finer kinds are rather tender for outdoor cultivation, especially in the northern United States; but they succeed well by forcing, and are handsome plants for the greenhouse or parlor. The odor from the flowers is apt to be offensive in close apartments.—The bulbs of the narcissus are said to abound in farina, and to contain an emetic principle to such an extent that those of the *N. poeticus*, *jonquilla*, and some others, were called *bulbi vomitarii* by the old herbalists. Similar properties exist in *N. odoratus*, *pseudonarcissus*, and *tazetta*; and in Europe they are administered in doses of 5 to 10 grains to produce nausea, and of 80 grains as an emetic. The extract is the best form in which the active principle can be exhibited medicinally; 2 or 3 drachms will destroy life in the course of a few hours. By some it has been employed in the treatment of whooping cough, but ac-

cording to Laenneo, though sometimes effectual, it is not more so than belladonna. The flowers are likewise employed in preparations on account of their sedative qualities, and those of the *pseudonarcissus* are not only emetic but a dangerous poison, occasionally producing serious consequences in infants who are allowed to swallow them.—The different forms of the narcissus have been carefully studied and arranged by Robert Brown, and again by the Rev. William Herbert ("Appendix to the Botanical Magazine," London, 1831). The genus is there divided into 6 other genera, after the mode adopted by Haworth (*Narcissiarum Monographia*, London, 1831), which, though convenient for their determination, has not met with much favor from botanists in general.

NARCISSUS. I. A mythical youth, son of the river god Cephissus and the nymph Liriope, who was remarkable for his beauty, but wholly inaccessible to love. The nymph Echo died of grief because he would not reciprocate her affection. One of his rejected admirers begged Nemesis to punish him, and the goddess caused him to fall in love with the reflection of his own figure in a spring. Under the influence of this passion he pined away, and after death was changed into the flower which bears his name. II. A freedman and secretary of the Roman emperor Claudius, over whom he acquired unbounded influence. For some time he used his power in subservience to the wishes of the empress Messalina; but when he found that she meditated his destruction, he determined to anticipate her, and revealing to Claudius her marriage with Caius Silius, convinced him that his own safety required her immediate sacrifice. The emperor consented to her imprisonment, but as he manifested reluctance to have her put to death, Narcissus sent a tribune to despatch her. Agrippina, whose intrigues in favor of her son Nero Narcissus had thwarted, had him removed to Campania, where he was murdered by her orders, A. D. 54. He is said to have amassed a fortune of 400,000,000 sesterces, equivalent to \$18,500,000. III. A Roman athlete, with whom the emperor Commodus was in the habit of contending in the arena, and who was afterward employed by Marcia to strangle his patron. For this crime Severus, on his accession, had him given to the lions.

NARCOTIOS (Gr. *vapov*, torpor), substances which when taken into the system affect the cerebral functions, stimulating and then producing drowsiness, which may be succeeded by stupor. Opium and morphia are familiar examples. Sedatives differ from narcotics in having no exciting influence.

NARD. See SPIKENARD.

NARRAGANSET BAY, on the S. E. coast of Rhode Island, extends from Point Judith on the W. to Seconnet on the E., and N. to Bullock's Point, 6 m. below Providence, being 38 m. long by from 8 to 12 m. wide. It receives the Pawtuxet, Providence, Pawtucket, and Taunton

river, and contains a number of islands, the principal of which are Rhode Island, Conanicut, and Providence. It is easily accessible, and affords excellent harbors and roadsteads. Newport, Bristol, Warren, and other towns are on its borders. It is well supplied with light-houses, and strongly fortified.

NARRAGANSETS, a tribe of Indians who formerly occupied the territory now comprised in the state of Rhode Island and the eastern part of Long Island. Shortly after the arrival of the pilgrims they manifested symptoms of hostility; and as an expression of sentiment Conaniticus, their chief, sent to Plymouth a bundle of arrows wrapped in the skin of a rattlesnake; to which Bradford, the governor, replied with the same skin filled with powder and shot. This significant retort secured, if not the good will, at least the peaceableness of the sagacious chief. In the Pequot war they aided the colonists, but not unanimously. In the winter of 1675, during King Philip's war, that chief having taken refuge with the tribe, the colonists, apprehending that they would join his cause, made a secret attack upon their principal fort, killing about 1,000 warriors, destroying all their provisions, and exposing those who escaped to cold and famine, of which very many died. The Narragansets from this time waged incessant war with the whites, and were soon exterminated.

NARROWS, THE. See **NEW YORK.**

NARSES, a general and statesman of the Byzantine empire, born about A. D. 473, died in Rome in 568. His original condition was that of a slave and a eunuch in the household of Justinian. He rendered important services to his master during the Nika sedition in 532, was appointed imperial treasurer, and was subsequently sent on several embassies. In 538 he was placed in command of the reinforcements which were sent to Belisarius, then waging war against the Goths in Italy; but his jealousy of Belisarius, whom he is supposed to have had instructions from Justinian to thwart, paralyzed the Roman arms and led to the capture of Milan by the Goths. Narses was consequently recalled in 539, and for the next 12 years his name is hardly mentioned in the Byzantine annals; but in the imperial councils he continued to exercise a predominant influence. He obtained command of a second expedition against the Goths in Italy in 552, and near Rome gained a complete victory over King Totila, who perished with 6,000 of his soldiers. This triumph led to the surrender of Rome and several of the strongest fortresses in central Italy. A vast barbarian army under Teias, the successor of Totila, was soon afterward defeated on the banks of the Sarno, near Naples, after a battle of two days, in which Teias was slain. The Franks and Alemanni, to the number of 75,000, now descended from the Alps, and spread themselves over the whole peninsula, devastating and destroying wherever they came. Narses waited until they had be-

come demoralized and weakened by rapine, and then attacked them at Casilinum in Campania, on their return northward, with such vigor that out of 80,000 men only 5,000 are said to have escaped from the battle. This victory utterly ruined the barbarian power in Italy, which once more became a province of the empire. Narses was rewarded by the appointment of governor of the conquered territory, and, fixing his residence at Ravenna, ruled it with the title of exarch for 15 years. Soon after the accession of Justin, being dismissed from office, he invited the Lombards to invade Italy, probably anticipating that he would be restored to power in order to repel them. In this he was disappointed, and he is said to have died of grief at the ruin which his treachery brought upon the country.

NARUSZEWICZ, ADAM STANISLAW, a Polish historian and poet, born in Lithuania in 1788, died at Janowiec, Galicia, in 1796. He was educated in a Jesuits' school, entered that order in 1748, travelled through Germany, France, and Italy, was appointed professor at Warsaw, and after the dissolution of the order became bishop of Smolensk, and subsequently of Luck. By the advice of his patron, King Stanislas Augustus Poniatowski, he devoted himself especially to the critical study of Polish history, and his "History of Poland," of which vols. ii. to vii. appeared during his lifetime (Warsaw, 1780 *et seq.*), and fragments of the first volume after his death, gained him the surname of the Polish Tacitus. Among his other works are a life of Gen. Chodkiewicz, a history of the Tartars, a translation of Tacitus, idylls, satires, and other poems, all of which belong to the best productions of the Polish literature of that flourishing period.

NARVA, a town and port of European Russia, in the government of St. Petersburg, on the left bank of the Narova, 80 m. S. W. from St. Petersburg; pop. about 5,000. It is surrounded with a rampart, and has 11 Greek and Lutheran churches, manufactories of nails, and productive fisheries. It was founded in the 18th century, and was formerly a member of the Hanseatic league, and celebrated for its commerce previous to the foundation of St. Petersburg. The mass of the people are of German descent. Near this town Charles XII., on Nov. 30, 1700, with an army of 8,000 Swedes, defeated more than 60,000 Russians under Peter the Great.

NARVAEZ, RAMON MARIA, duke of Valencia, a Spanish soldier and statesman, born in Loja, Andalusia, Aug. 4, 1795. He was early engaged in military operations, and was wounded during the capture of Castelfolli in 1822. In 1828 he was compelled to withdraw before the French army of intervention, and lived in retirement until about 1884, when he was again wounded in the battle of Mendigorria. In 1836 he acted under the orders of Espartero, and the reputation which he then gained by defeating the formidable Carlist gen-

eral Gomez (Nov. 25, 1886) led to his advancement. In 1888 he succeeded, by his rigorous measures against the brigands who infested the province of La Mancha, in restoring tranquillity to that part of the country. He was appointed captain-general of Old Castile and general of an army of reserve. He had also been elected to the cortes as member for Seville, and on the formation in that city of a revolutionary junta by Cordova, he repaired thither to aid that general in his movements against Espartero, between whom and himself there existed a strong feeling of jealousy; but the insurrection was suppressed, and Narvaez was compelled to seek refuge in France (1840). While there he continued his machinations against the Spanish dictator, in conjunction with Maria Christina; and in 1843 he placed himself at the head of the Christinos, landed at Valencia, defeated Gen. Seoane at Torrejon de Ardoz (July 22), and made his entry into Madrid, which led to the overthrow of Espartero. In 1844 he became prime minister, and at the same time he was created field marshal, count of Canadas Altae, and duke of Valencia. Maria Christina was permitted to return to Madrid, and the opponents of the constitution of 1845 were put down by the iron rule of Narvaez. His arbitrary disposition gave offence to many members of his own party, and brought him into collision with Maria Christina herself. He resigned in Feb. 1846; but so indispensable was his energy and his military ability in quelling disturbances and in ruling the country, that, after having officiated for a short time as ambassador in Paris, he was recalled to power in 1847, but soon again dismissed on account of ceaseless quarrels with Maria Christina. On Oct. 20, 1849, he was once more recalled, and confirmed in power in 1850 by the support of a majority of the people. The attitude of the nation toward foreign powers began to assume greater dignity under the administration of Narvaez, who opposed the British government's attempt to interfere in Spanish affairs with a firmness which led to the withdrawal of the British minister (Sir Henry Bulwer) from Madrid, and to the interruption of diplomatic relations between the two governments until a reconciliation was effected by King Leopold of Belgium. His great influence in the government provoked at length the jealousy of the queen, and caused him to tender his resignation, Jan. 10, 1851, to become ambassador to Vienna. After Espartero's withdrawal from power (July 14, 1856), and O'Donnell's brief term of office, Narvaez was again called upon to preside over the cabinet (Oct. 12), but without special office, the portfolio of foreign affairs being confided to the marquis of Pidal. The concordat of 1851 with the holy see, which had been modified on various subsequent occasions, was restored to its original character immediately after his advent to power (Oct. 13). The outbreak at Malaga on Nov. 16 was put down by force of arms, and all parts

of Spain except Catalonia were relieved from martial law. A general amnesty to the Carlist rebels of 1855 and 1856 was promulgated, April 8, 1857. Narvaez now impaired his popularity by strengthening the influence of the crown in the senate, making the dignity of senator hereditary, and admitting as members to it the dignitaries of church and state. He also caused stringent laws to be enacted against the liberty of the press, and introduced laws for the administration of municipal and provincial affairs after the model of those of France, which were adopted by the cortes, but alienated from him the sympathies of a considerable portion of the conservative party. Finally he tendered his resignation, Nov. 1, and his cabinet was succeeded by the Armero administration, Nov. 15, 1857.

NARWHAL, a cetacean mammal, of the genus *monodon* (Linn.), frequenting the arctic seas, and occasionally straying to northern Europe; its popular name is sea unicorn. It has no proper teeth, but in the males, and sometimes in the females, there are 2 tusks arising from the intermaxillary bone; these are true incisors, but only one, usually the left, is developed, the other remaining rudimentary in most cases; the former is long, pointed, spirally twisted and grooved, and directed straight forward, growing through life from a permanent pulp as in the elephant. The tusk, of solid ivory and 6 or 8 feet long, is a most formidable weapon in such an active and powerful animal, and is sometimes driven deeply into the timbers of a ship. According to Mulder there are 2 other small teeth, contained in the gum of the upper jaw. In the only well ascertained species (*M. monoceros*, Linn.) the body may attain a length of 15 or 16 feet, and the tusk from 6 to 10 additional; there is no well marked separation between the head and body; the forehead rises suddenly, and the blow-hole is on the top of the head; the eyes and mouth are small, and the lips unyielding; the pectorals are small for the size of the animal; the caudal is transverse, bilobed, and about 4 feet wide; instead of a dorsal fin there is a low fatty ridge 2 or 3 feet long in the middle of the back. The prevailing color is dark gray above with numerous darker spots, white on the sides and below, on the former with grayish spots; some specimens are very light-colored, and the young are said to be bluish gray. The food consists principally of cephalopod mollusks, and, on the authority of Scoresby, of flat and other fishes, which it transfixes with its horn; other uses of this weapon are for breaking the ice for the purpose of obtaining air, and for defence. Narwhals are sometimes seen in bands of 10 to 20, sporting about whaling ships, elevating their tusks above the water, and playing about the bows and rudder; they are migratory, and their appearance is hailed with delight by the Greenlanders, who consider them the certain forerunners of the right whale; and this, the result of their ex-

perience, is probably due to both using the same kind of food. They are harpooned for their ivory, oil, and flesh; the last is considered a delicacy as food by the Greenlanders. The blubber is from 2 to 4 inches thick, and yields a very superior oil. The ivory of the tusk is very hard and white, and takes a high polish; it was formerly a valuable article of commerce, when the origin of the horns was less known; a famous throne of the kings of Denmark is said to be made of the ivory of narwhals' tusks. Ignorance, superstition, and exaggeration have made a variety of fabulous animals from the basis afforded by the tusk or horn of the narwhal.

NASEBY, a village in Northamptonshire, England, where was fought a decisive battle between the royal forces commanded by Charles I. and those of the parliament under Fairfax, June 14, 1645. Early in June Fairfax, who was besieging Oxford, alarmed at the intelligence of the capture of Leicester by the royal army, moved off through Buckinghamshire into Northamptonshire, without any certain knowledge of the course which the king was taking. Early on the morning of the 14th the hostile armies, about equal in numbers, confronted each other, the parliamentarians occupying a strong position near Naseby, and the king's troops being drawn up one mile south of Harborough. The royal centre was commanded by the king in person, the right wing by Prince Rupert, and the left by Sir Marmaduke Langdale. Fairfax, supported by Skippon, commanded the centre of his army, with Cromwell on his right wing and Ireton on his left. Yielding to the impetuous counsels of Rupert, backed by the young nobles and gentry, Charles gave the order for an attack, and Rupert with his cavaliers charged with such fury upon Ireton that the left wing of the parliamentary army was broken and put to flight, its leader after a stout resistance being wounded and taken prisoner. Rupert, however, "incorrigible in his rashness," repeated the error whereby the battles of Edgehill and Marston Moor had been lost, and, instead of supporting his royal kinsman, detached himself from the main battle to pursue the fugitives. The royal centre was meanwhile hotly engaged with the troops under Fairfax and Skippon, the generals on both sides displaying a valor and skill which for a long time rendered the issue uncertain. On the royal left Cromwell, after an obstinate encounter, routed the forces of Sir Marmaduke Langdale, and, leaving a few squadrons to watch the fugitives, fell suddenly upon the rear of the royal centre, which, unsupported by either of its wings, almost immediately surrendered. One regiment alone held out for the king, but was finally broken by repeated charges. At this moment Rupert returned from his needless pursuit of Ireton's troops, with his men and horses exhausted and the time for effective aid gone by. Charles, who during the battle had, according to Hume, "displayed

all the conduct of a prudent general and all the valor of a stout soldier," urged them by a final charge to redeem the day; but the appeal was disregarded, and the king was only enabled to insure his personal safety by a precipitate flight. The royalists lost 800 killed and 4,500 made prisoners, beside their artillery and ammunition and several thousand stand of arms. A number of private letters between Charles and his queen, subsequently published under the title of "The King's Cabinet Opened," also fell into the hands of the parliamentarians. The latter lost 1,000 killed. This battle is vividly described in one of Macaulay's ballads, of which it is the subject.

NASH, a N. E. co. of N. C., bounded S. W. by Contentny creek and N. by Swift creek, and intersected by Tar river; area, 640 sq. m.; pop. in 1850, 10,657, of whom 4,056 were slaves. The surface is uneven. The productions in 1850 were 824,146 bushels of Indian corn, 118,449 of sweet potatoes, 845 bales of cotton, and 5,888 lbs. of tobacco. There were 4 grist mills, 8 saw mills, 8 turpentine distilleries, 17 churches, and 726 pupils attending public schools. Capital, Nashville.

NASH. I. ASNER, an American lawyer and politician, born in Prince Edward co., Va., died in Philadelphia in 1786. He went in early life to Newbern, N. C., where he was a prominent lawyer for many years. He represented Newbern in the first provincial congress, which met there Aug. 25, 1774, and throughout the revolution was active in the whig cause. He was one of the provincial council in 1775, and of the congress and the committee that formed the state constitution in 1776; was elected to the house of commons from Newbern in 1777, and from Craven co. in 1778. In 1779 he was speaker of the senate, and in December of that year was chosen governor of the state. The period of his administration was by far the gloomiest portion of the revolutionary war in North Carolina, and he seems to have been of a too easy temper or too feeble health for such times. His first assembly, April 17, 1780, made Gen. Caswell the commander of all the militia of the state, though the constitution made the governor the commander-in-chief; and at its session in September it appointed a board of war to manage the military operations of the state, a still larger invasion of his prerogatives. When the assembly met in January, it made the governor a member only of a "council extraordinary," to which the supreme executive authority was confided. In the spring of 1781 he declined to serve longer, and was succeeded by Gov. Burke. From 1782 until his death he was a member of the continental congress. II. FRANCIS, an American soldier, brother of the preceding, died in 1777. While clerk of the superior court for Orange co., N. C., he held a captain's commission under the crown. In this capacity he served under Gov. Tryon against the regulars, and in the battle at Alamance in 1771. He was a

member of the provincial congress which met at Hillsborough, Aug. 21, 1775, and was appointed by that body lieutenant-colonel of one of the two regiments then raised for the continental service. In Feb. 1777, he was made a brigadier-general by the continental congress, joined Gen. Washington, and commanded a brigade at the battle of Germantown, Oct. 4 of the same year, where, though in charge of the reserve, he was mortally wounded by a cannon ball. III. FERNIXO, an American jurist, son of Gov. Abner Nash, born in Newbern, N. C., Feb. 9, 1781, died in Hillsborough, Dec. 5, 1858. He was graduated at Princeton in 1799, and at once applied himself to the study of the law. In 1804-'5 he was a member of the house of commons, in which he represented his native town. In 1808 he removed to Hillsborough, where he resided during the rest of his life. In 1814-'15 he represented Orange co. in the legislature, and in 1827-'8 the town of Hillsborough. He was appointed judge of the superior court in 1818, resigned in 1826, and was reelected in 1836. In 1844 he succeeded Judge Gaston on the bench of the supreme court, of which he became the chief justice upon the resignation of Judge Ruffin. This place he occupied till the close of his life.

NASH, JOSEPH, an English water color painter, born about 1818. He has a great reputation as a painter of architecture, and in his "Architecture of the Middle Ages" (fol., 1838), and "Mansions of England in the Olden Time" (4 vols. fol., 1839-'49), lithographed in colors from his drawings, has produced two of the most magnificent illustrated works ever published. He has occasionally attempted historical scenes from Shakespeare and Scott, and miscellaneous subjects, such as the "Queen's Visit to Lincoln's Inn Hall" (1846), &c.

NASH, RICHARD, better known as Beau Nash, born in Swansea, Glamorganshire, Oct. 18, 1674, died in Bath, Feb. 8, 1761. After a preliminary education at Caermarthen school, he was entered at Jesus college, Oxford, where his career was chiefly distinguished by dissipation. To preserve him from an imprudent marriage, he was at 17 years of age removed from the university, and a commission in the army was procured for him; but wearying of the monotony of barrack life, he entered himself a student of law in the Middle Temple. His life in reality was devoted to pleasure, and with resources supplied from the gaming table he became a leader of fashionable society and an accomplished man about town. On the occasion of an entertainment given by the members of the Middle Temple to William III., he conducted the pageant with so much tact and address that the king offered to knight him. Nash, sensible of his uncertain means of support, declined the honor. In 1704 he visited Bath, then just rising into importance as a watering place, but which had been placed under the ban of a Dr. Radcliffe, who, in retaliation for

an alleged insult, had threatened to write down the waters. At this juncture Nash stepped forward to the assistance of the inhabitants, and, getting himself appointed master of ceremonies, succeeded in a short time in securing for the place the reputation of an agreeable resort for valetudinarians as well as mere seekers of pleasure. Decency of dress and civility of manners were enforced in the public resorts, an elegant assembly room was built, streets and buildings were improved, and in process of time a handsome city was established in place of what had been only a dull provincial town. Nash himself shared in the prosperity which he had promoted, and, from the influence which he wielded and the deference in which he was held by citizens as well as visitors, was styled the "king of Bath." Supporting himself still by the gaming table, where he played with skill and with uniform fairness, he lived in great pomp, travelling, while in the heyday of his prosperity, in a coach and six with outriders, and dispensing charities with reckless profusion. It is mentioned to his credit, that notwithstanding his own habit of gambling he took pains to put young and thoughtless persons on their guard against indulgence in the practice. Toward the close of his life his glory perceptibly waned, and after the act of parliament against gambling had deprived him of his principal means of support, he lived in comparative indigence. He was honored by a public funeral, and a marble statue of him was placed in the pump room of the king's bath. Nash was ungainly in person, with coarse and ugly features, and dressed in a style of tawdry magnificence. A life of him by Goldsmith, published anonymously in 1762, is included in Peter Cunningham's edition of Goldsmith's works (4 vols. 8vo., London, 1854).

NASH, THOMAS, an English pamphleteer and dramatist, born in Lowestoft, Suffolk, in 1558, died in London in 1600 or 1601. He took the degree of B. A. at Cambridge in 1584, but was subsequently expelled for satirizing the authorities. For several years he travelled on the continent without any settled employment. In 1589 he fixed his abode in London. The prelatists and Puritans being then engaged in a war of vituperation, Nash espoused the cause of the former, and wrote a series of bitter pamphlets against their opponents, the principal of which are entitled: "Pap with a Hatchet," "An Almond for a Parrot," "A Countercuffe to Martin Junior," and "Martin's Month's Minde." He aided Marlowe in writing "Dido, Queen of Carthage," and produced in 1592 a comedy of his own styled "Summer's Last Will and Testament," which was acted before Queen Elizabeth. Nash's dramas were so ill received that he sank into extreme poverty. He describes his forlorn condition in his "Pierce Penilesse, his Supplication to the Divell," which appeared in 1592. He had recourse once more to his old trade of pamphleteering, and assailed

the unfortunate Dr. Gabriel Harvey with all the satire and pungency of which he was master. The doctor made a stout defence, but he was no match for Nash, and the war became so fierce that the archbishop of Canterbury ordered the books of both combatants to be seized. In 1597 Nash produced a satirical play called "The Isle of Dogs," the representation of which led to his confinement in the Fleet prison.

NASHUA, an important manufacturing city of Hillsborough co., N. H., at the junction of the Merrimack and Nashua rivers; pop. in 1860, including Nashville, at one time a separate municipality, 10,065. The Nashua river has here a fall of 65 feet in about 8 m., affording great water power. There are several large manufacturing associations, of which the most extensive is the Nashua manufacturing company, chartered in 1823, with a capital of \$1,000,000. It has 4 mills, which contain 40,000 spindles and 1,200 looms, consume 5,500,000 lbs. of cotton, and produce 15,600,000 yards of cloth per annum, employing about 150 males and 850 females. The Jackson company, with a capital of \$600,000, runs 3 mills with 22,000 spindles and 700 looms, consuming 3,500,000 lbs. of cotton, and producing 9,000,000 yards of cloth per annum. The Harbor manufacturing company, with a capital of \$75,000, runs 5,000 spindles and 100 looms, and manufactures 1,100,000 yards of cotton cloth per annum. There are also an extensive bobbin and shuttle factory, 2 large iron foundries, 2 large machine shops, a forging shop, a card and fancy paper manufactory, an edge tool manufactory, and a watch factory. There are also corporations for the manufacture of iron, locks, &c. Nashua contains 10 churches (1 Baptist, 3 Congregational, 1 Episcopal, 2 Methodist, 1 Roman Catholic, 1 Unitarian, and 1 Universalist), 8 banks, 1 savings bank, and 2 newspaper offices. It has communication by railroad with all the principal cities of New England, the Nashua and Lowell, the Worcester and Nashua, the Nashua and Concord, and the Nashua and Wilton railroads all centring here.

NASHVILLE, a city, port of entry, and the capital of Tennessee, and seat of justice of Davidson co., situated on the Cumberland river, 200 m. above its junction with the Ohio, in lat. 36° 9' 33" N., long. 86° 49' 3" W.; pop. in 1850, 18,140; in 1860, 23,715. The city is built chiefly on the south side of the river, on the slopes and at the foot of a hill rising about 200 feet above the water. The Cumberland is navigable by steamboats of 1,500 tons for 50 m. above the city, and by smaller boats to the falls, 500 m. There are 5 railroads radiating from Nashville, viz.: the Tennessee and Alabama, Louisville and Nashville, Edgefield and Kentucky, Nashville and Chattanooga, and Nashville and north-western. The city is generally well built, and there are numerous imposing public and private buildings. One of the finest of the former is the new capitol, situated on an eminence 175 feet above the river

and constructed inside and out of a beautiful variety of fossiliferous limestone. It is 8 stories high, including the basement. At each end there is an Ionic portico of 8 columns, each 4 feet 6 inches in diameter and 88 feet 5 inches high, and each of the sides has also a portico of 6 columns. A tower rises above the centre of the roof to the height of 206 feet from the ground. It has a quadrangular rusticated base, 42 feet high, surmounted by a circular cell 37 feet high and 26 feet 8 inches in diameter, with 8 fluted Corinthian columns, designed from the choragic monument of Lysicrates at Athens. The dimensions of the whole building are 188 by 288 feet, and it cost over \$1,000,000. It is approached by 4 avenues which rise from terrace to terrace by broad marble steps. The edifice is considered the handsomest state capitol in the Union. The new court house is a large building on the public square, with an 8-columned Corinthian portico at each end, and a 4-columned portico at each side. The state bank is a handsome Doric building. Among the other prominent edifices are the gaol, penitentiary, theatre, odd fellows' and masonic halls, city hospital, university, and school houses. There are two fine bridges over the Cumberland river: one, a railroad bridge of wood, with an immense draw of 280 feet, and 2 stationary spans, each of 200 feet, was finished in 1859 at a cost of \$240,000; the other, a wire suspension bridge of more than 700 feet span, and 110 feet above the water, was begun in 1850, and cost about \$100,000. The city water works were constructed in 1833, and the total expense up to 1860 has been more than \$500,000. The water is raised from the river to 4 reservoirs, which have an aggregate capacity of 1,600,000 gallons. Gas was introduced into the city in Feb. 1850.—Among the public institutions, the most important is the Nashville university, incorporated in 1785 under the name of Davidson academy, and in 1806 as Cumberland college. It received its present title in 1826. It has now (1860) about 200 students in the literary department, and 400 in the medical school. The literary department was united in 1855 with the "Western Military Institute," and took the latter name. The students receive in addition to their classical education a quasi-military training. The main building is a handsome Gothic edifice of stone. It has a library of 15,000 volumes. The medical department, opened in 1850, also occupies a fine building, and possesses an extensive museum, beside having the charge of a valuable mineralogical cabinet of 20,000 specimens collected by the late Dr. Gerard Troost. Shelby medical college is a new and flourishing institution. The female academy, founded in 1816, has about 450 pupils. A public school system went into operation in 1855, and there are now 8 large schools, with an aggregate attendance of 2,000 pupils. The Roman Catholics have 4 schools and a theological seminary. The historical society has a good museum and library. The

state library in the capitol has 40,000 volumes, and the mechanics' library association 5,000. A young men's mercantile library association has recently been formed. The principal benevolent institutions are the city hospital, Protestant and Catholic orphan asylums, house of industry, hospital of the sisters of charity, workhouse established in 1859, and the Tennessee blind asylum founded in 1844. The penitentiary is a handsome stone edifice built around an open court, and has about 400 convicts. There are 27 churches, including a Roman Catholic cathedral, 8 banks, a savings bank, 8 insurance companies, and several large hotels, one of which, the Maxwell house, now building (1860), will accommodate 600 guests. A paid fire department, with 3 steam fire engines, was introduced in 1860. The periodical press comprises 5 daily, 8 weekly, and 8 monthly publications.—The commerce of Nashville is very large, being carried on by river and railroads, and by turnpike roads, to the construction of which the city has devoted a great deal of attention. The revenue of the port amounts to about \$40,000 a year, but the government has not erected a custom house. The tonnage of the district, June 30, 1859, was 5,120, all enrolled and licensed; there was no return of the value of imports and exports. The average annual shipments are 30,000 bales of cotton, 6,000 hhds. of tobacco, 2,000,000 bushels of wheat, 6,000,000 of Indian corn, 10,000 casks of bacon, 25,000 hogs, and 2,500 tierces of lard. The neighborhood is a famous stock-raising country, and has a high reputation for blood horses, jackasses, mules, cattle, sheep, hogs, and Cashmere goats. The leading business of the city is in dry goods, hardware, drugs, and groceries. Book publishing is carried on more extensively than in any other western town, and the publishing house of the southern Methodist conference is one of the largest book manufactories in the United States. The manufacturing are less important than the commercial interests. There are 3 flour mills, 8 or 10 planing mills, and 8 or 10 machine shops. The value of taxable property is about \$15,000,000. Seven miles from the city is the state lunatic asylum, and 12 m. E. is the Hermitage, the celebrated residence of Andrew Jackson. The municipal government is vested in a mayor, 8 aldermen, and 16 councilmen.—The first permanent settlement at Nashville was made in 1779-'80, and the town was incorporated in 1784, received a city charter in 1806, and was made the state capital in 1812.

NASMITH, DAVID, a Scottish philanthropist, born in Glasgow, March 21, 1799, died in Guildford, England, Nov. 17, 1839. He began his career by imparting religious instruction to prisoners, and laboring to establish Sunday schools and Bible societies. In 1821 he became secretary-general to the united religious and benevolent societies of Glasgow, and afterward engaged in the formation of associations for the moral and religious improvement of

young men in large towns, 70 of which associations he was instrumental in establishing in the British isles, France, and America, between 1823 and 1826. A still more important project of his was the institution of town and city missions. The Glasgow city mission, established in 1826, and which may be regarded as the model of all succeeding ones, comprehended 8 denominations of Christians, and had in its employ 8 missionaries, before the first year of its existence expired. In 1828 he entered regularly on his career as a missionary, visiting Dublin and the principal cities of the south of Ireland. In 1830 he travelled over the greater part of the United States and Canada, and on returning to Europe proceeded to France, and formed missions in Paris and Havre. In 1835 he removed to London, where a mission was established on a very humble scale, only 4 missionaries being at first employed, the aggregate of whose salaries amounted to £297 per annum. In 1855 it had 320 missionaries, and the sum total of their salaries exceeded £28,000. He continued to exert himself to the last for the advancement of his religious and philanthropic projects, and was engaged in organizing a town mission in Guildford when he was seized with the sickness that caused his death.—See Dr. Campbell's "Memoirs of David Nasmith" (London, 1844).

NASSAU, a N. E. co. of Fla., bordering on the Atlantic, separated from Georgia on the N. and N. W. by St. Mary's river, and bounded S. by the Nassau river; area, 576 sq. m.; pop. in 1850, 2,164, of whom 1,077 were slaves. It has a level surface and sandy soil. The productions in 1850 were 404,805 lbs. of rice, 29,812 bushels of Indian corn, 279 bales of cotton, and 44 hogsheads of sugar. There were 3 grist mills, 1 saw mill, 1 tannery, and 1 turpentine manufactory. Amelia island, included in the county, occupies the whole of the coast. Capital, Nassau Court House.

NASSAU, an island in the Pacific ocean, in lat. 11° 30' S., long. 165° 30' W., discovered by Capt. Sampson, of the American whaler whose name it bears, in 1835. It is low and apparently uninhabited, but wood and water are plentiful. It is supposed to be identical with Ranger island, which an English whale ship so called reported in 1848 to be in lat. 11° 35' S., and long. 166° 45' W.

NASSAU, the capital of New Providence, the most important of the Bahama islands, in lat. 25° 5' N., long. 71° 21' W.; pop. about 7,000. It is the seat of government of the Bahamas, and has a good harbor for vessels drawing 12 to 15 feet of water. The town is built on a rather steep hill, but is well laid out, and contains handsome residences and public buildings. It is a place of considerable trade. The chief exports are cotton, pimento, and salt; and the imports consist of provisions, lumber, &c. The climate is remarkably mild and healthy, and the place is resorted to by invalids from the north.

NASSAU, a German duchy, bounded by the Prussian Rhenish provinces, the grand duchy of Hesse-Darmstadt, the electorate of Hesse-Cassel, Hesse-Homburg, and Frankfort; area, 268 sq. m.; pop. in 1859, 439,454, comprising 229,708 Protestants, 202,087 Roman Catholics, 530 German Catholics, 188 Mennonites, and 7,016 Jews. The Westerwald mountains cover nearly the whole N. and the Taunus mountains the whole S. part of the duchy. The valleys of Nassau, on the shores of the Rhine and Lahn, are among the most beautiful in Germany. Nassau also contains the famous watering places Ems, Wiesbaden, Schwalbach, and other noted mineral springs. Among the best known wines produced in Nassau are those of Hockheim (whence the general name of hock), Marcoobrunn, Rudesheim, Asmannshausen, and above all those of Johannisberg, the property of the Metternich family. The other products are fruit, hemp, flax, grain, tobacco, iron, lead, copper, and other minerals. The forests abound with game and with timber and fire wood. The smelting and manufacturing of metals form an important branch of industry. There are also manufactories of leather, paper, and several other articles.—Nassau is divided into 28 bailiwicks, and governed by a duke, who, according to the new constitutions of 1817 and 1848, is assisted by a ministry and by a chamber. The receipts amounted in 1859 to about \$2,000,000, the expenditures to \$2,200,000, and the public debt to nearly \$5,000,000. The federal contingent of Nassau consists of 5,498 soldiers. The Protestants of the duchy are subject to the bishop of Wiesbaden, and the Catholics to the bishop of Limburg. Capital, Wiesbaden. The summer residence of the duke is Biebrach.—In Germanic antiquity Nassau was inhabited by various tribes of Alemanni. After their incorporation with the Frankish empire various families rose into prominence, among which was that of Lurenburg. Rupert I. of Lurenburg married a countess of Arnstein, and his son Walram I., together with his nephew, first assumed the title of count of Nassau, after a small rural settlement of that name, which is mentioned in a public record as early as A. D. 794. Walram's grandsons, Walram II. and Otho, became the founders of the Walram and Otho or Gueldrian line. The German princes of Nassau are descendants of the former, and the Dutch princes of Orange of the latter, hence called Nassau-Orange. Walram II. was the father of Adolphus of Nassau, who was king of Germany from 1292 to 1298. His grandsons Adolphus II. and John I. divided their inheritances into several branches, which were eventually reunited by Louis II., who died in 1625. His sons again divided the country into several branches, some of which are now extinct, while that of Nassau-Weilburg is the more immediate source of the present line of dukes, who acquired their sovereignty by joining the confederation of the Rhine (1806). The treaty of 1814 restored to them

the territory on the left bank of the Rhine, which they had lost in 1795. All the German possessions of the Nassau-Orange line were acquired by the dukes of Nassau in exchange for territory ceded by them to Prussia. They also acquired at that time the hereditary right to the succession of Luxemburg, which however they sold to Holland in 1839 for about \$350,000. More liberal institutions, which had already been projected and partly called into life in 1847, were secured to the duchy by the revolution of 1848, when the domains of the crown became public property, and when the upper house (*Herrenbank*) was supplanted by a popular legislative assembly, and a constitution was promulgated. The subsequent reaction in German politics gave rise in Nassau to the withdrawal of the radical members from the chambers, after which a new electoral law (Nov. 1851) was passed, the effect of which was to purge it of the democratic element, and to give a majority to the government.—The present duke Adolphus was born July 24, 1817, succeeded his father William Aug. 20, 1839, and married in 1844 a daughter of the grand duke Michael of Russia, who died in 1845. His second wife, a daughter of Prince Frederic of Anhalt-Dessau, whom he married in 1851, has borne him William, the crown prince (1852), and Prince Francis (1859).

NASSAU or POGGY ISLANDS, two islands off the W. coast of Sumatra; pop. about 1,000. The northern island is situated between lat. 2° 32' and 2° 52' S., and the southern between 2° 50' and 3° 20' S., and both are included between long. 99° 37' and 100° 41' E. They consist of high steep hills, covered with timber of very large size, and well suited for nautical purposes. The sago tree constitutes the chief article of food. The natives are divided into small tribes, each tribe occupying the banks of a river and living in one village.

NAST, WILLIAM, D.D., an American clergyman, born in Stuttgart, Germany, about 1800. He was educated at the university of Tübingen with a view of entering the ministry of the established church, but preferred literary pursuits, and after graduating became connected with the press. In 1828 he came to America, was engaged as a teacher at West Point, and subsequently became a professor in Kenyon college, Ohio. In 1835 he joined the Methodist Episcopal church, and was soon after licensed to preach. At the conference of the same year he was appointed to Cincinnati, O., with a view of establishing a German mission in that city. This mission proved very successful, and in 20 years German Methodist churches have been established in almost every part of the United States, and in various parts of Germany and Scandinavia. Dr. Nast has edited the "Christian Apologist," and translated a large number of Methodist works into German, beside writing several valuable books in that language. He is now engaged, in connection with his editorial duties, in writing a com-

mentary on the New Testament in the German language, parts of which have appeared.

NATAL, a British colony on the S. E. coast of Africa, about 300 m. N. E. from British Caffraria, from which it is separated by a thinly inhabited country called Caffraria Proper; pop. according to the "Cape Almanac" for 1858, 108,700, including 6,550 whites. It lies between lat. 28° and 31° S. and long. 29° and 31° E. It is bounded N. and N. E. by the rivers Tugela and Umzimyati, which separate it from the country of the Zooloo Caffres; S. E. by the Indian ocean; S. and S. W. by the river Umzimkooloo, which divides it from Caffraria Proper; and W. and N. W. by the Kahlamba or Drakenberg mountains, dividing it from the Orange River republic. (See BOXES.) Its length is about 200 m.; breadth from the sea to the mountains about 100 m.; area, 18,000 sq. m. For police purposes the colony has been divided into 6 districts, 3 of which are in the coast division, and 3 in the interior. The settled parts are divided into counties, but the region inhabited by natives only has not yet been so divided. There are two towns, Pietermaritzburg, the capital, and D'Urban, the port, beside a number of villages scattered over the colony. Pietermaritzburg contains 500 houses, with a white population of about 1,600. D'Urban has 450 houses, and a white population of about 1,200. The latter town stands on the N. side of Port Natal, a circular basin about 10 m. in circumference, communicating with the sea by a narrow channel. Its mouth is obstructed by a sand bar, which since recent improvements admits vessels drawing from 15 to 20 feet of water; and there is no doubt that the depth is capable of being further increased.—The country rises from the sea coast in a series of terraces to an elevation of several thousand feet, and presents many varieties of climate, soil, and scenery. Along the Indian ocean is a belt of undulating or hilly land about 15 m. broad, producing sugar, coffee, indigo, and almost every other tropical plant, together with the mulberry, olive, vine, oats, beans, potatoes, and Indian corn, and diversified with occasional tracts of forest. Succeeding this belt is a higher tract displaying the productions of a temperate climate; still further inland is a fine grazing district, and back of this a succession of hills extending to the foot of the Kahlamba mountains, which rise abruptly like a wall 8,000 feet above the sea, and nearly 4,000 feet above the country at their base. The climate is exceedingly pleasant and healthful. In the neighborhood of the coast the weather is warm, the average temperature being about 74° in summer and 68° in winter; but in the elevated districts it is much cooler. The rainy season continues from March to the end of September, during which violent thunder storms are frequent. The grazing country produces abundant crops of wheat, oats, and other cereals of the temperate regions, and excellent apples, pears, walnuts, peaches,

apricots, and nectarines. From the coast upward the whole is well watered by numerous streams and several considerable rivers, none of which are navigable. All the rivers are low in the dry season, but become full in a few hours in rainy weather, and rush down like torrents. Along the coast the soil is sandy, with masses of erupted rocks and sandstone interspersed. The high lands are composed of stratified sandstone, with a vein of granite running in a N. E. direction; and the soil is mostly a friable loam. The coast line, extending from high water mark 5 or 10 m. inland, is said to be peculiarly adapted for the growth of cotton; and it is estimated that 1,000 sq. m. of this district are capable of producing the most valuable of the cottons of America without the accompanying drawback of a climate unsuited to the English constitution. Mr. McLeod, in his "Travels in Eastern Africa," says: "The yield of one acre having 6,000 plants on it averaged 2½ lbs. of seed cotton per plant, which, when reduced by the cotton-cleaning gin, gave 1½ lbs. of clean cotton per plant. There are at the lowest computation 640,000 acres on the lower or coast line terrace of the colony which will produce cotton of this quality, so that our Liverpool merchants may look forward to a supply of no less than 4,800,000,000 lbs. of cotton from one of the smallest and latest acquired of our colonies." There are also 1,280,000 acres capable of producing sugar; the saccharine qualities have been proved to be stronger than the Mauritian sugars, and not surpassed by the best Trinidad. The virgin soil is said to yield 3 to 4 tons of sugar per acre. Natal promises to prove very rich in mineral resources. Iron ore is found in many places, and copper, tin, and lead have been discovered. Coal is also found, but it is not of a very good quality. The hippopotamus, crocodile, leopard, hyæna, elephant, buffalo, and eland, several varieties of antelope, and snakes, are all found in different parts of the country.—The white population comprises about 3,400 of British and 2,800 of Dutch descent, and a small German settlement of about 350 on the banks of the Umgem. The colored population are Zooloos, of the same family as the Caffres. They are a pastoral people, and disinclined to agricultural labor; they are as noted for their honesty as the Caffres are for their cattle-stealing propensities. The recorder of Natal states, in 1859, that colonial history presents no instance of 6,000 to 7,000 colonists living in such security amid 100,000 aborigines. Agriculture is progressing, and in 1859 there were about 50,000 acres under cultivation, producing upward of 600,000 bushels of Indian corn. There were in 1859 7 sugar mills of great power in operation. The exports amounted to £15,000 in 1850, £20,000 in 1852, £45,000 in 1855, £78,000 in 1857, £91,000 in 1858, and £100,000 in 1859. They include beef, pork, tallow, hides, grain, flour, butter, wool, arrowroot, ivory, &c. The imports in 1856 amounted to £102,513, a consid-

erable proportion of which was machinery for the manufacture of sugar and flour.—In 1855 there were 81 schools, attended by 1,295 scholars, supported or assisted by government. A superintendent of education was appointed in 1859, and £2,022 was voted for educational purposes in 1860. There are several schools under the care of missionaries, and some excellent ones both for Europeans and natives established under the auspices of the English bishop; £5,000 per annum is set apart from the revenue for the education of the natives. There are public libraries and mechanics' institutes at Pietermaritzburg and D'Urban. There is a handsome cathedral at the capital, a large church at D'Urban, and several churches at other places, belonging to various denominations. There is also a Roman Catholic bishop. The American mission is composed chiefly of Presbyterian and Congregational ministers; and there are about 10 stations in different places.—Natal has a lieutenant-governor (in 1860, John Scott), under the general control of the governor of the Cape of Good Hope. The revenue in 1855 was £34,050, and the expenditures £33,895. There is a council composed of 4 chief officers, and 12 members who are elected by the people. The qualification for voters is the possession of freehold property worth £50, or the occupation of a house or land at a rent of £10 a year; all voters are eligible to membership. The Roman-Dutch law is in force, but trial by jury, both in criminal and civil cases, has been introduced. A constitutional charter was promulgated for the colony in 1859, similar to that of the Cape of Good Hope, and municipal institutions were at the same time granted to the principal towns.—The Portuguese discovered the coast of Natal on Christmas day, 1498, and named it in honor of the day. It was visited and favorably reported upon, toward the close of the 17th century, by Dampier, Woodes Rogers, and several Dutch navigators. Subsequently a Dutch expedition purchased the territory from some native chiefs. Its actual colonization, however, was not projected till 1828. In that year Mr. Thomson, a merchant of Cape Town, and Lieuts. Farewell and King of the English navy, in the course of a trading voyage to the E. coast of Africa, put into Natal harbor. In 1824 Lieut. Farewell, having visited it again, obtained from the king of the Zooloos, who had conquered the country, a grant of land around Port Natal, where he hoisted the British flag and took possession. In 1834, in consequence of an application to the governor of the Cape of Good Hope from the Zooloo king for a white settlement to be formed at Natal, a few emigrants proceeded from that colony. In 1835 the American missionaries commenced operations in the territory; but nothing was done on a large scale till about 1838, when the emigrant Dutch farmers who were dissatisfied with the British rule in the Cape Colony ascended to the sources of the Orange river, and found

their way across the Quathlamba range. In 1840 so many of these people had arrived in Natal that it was estimated there were 600 men among them capable of bearing arms. They founded Pietermaritzburg with a view to make it the capital of their settlement, which they called the republic of Natal, and delegated the necessary powers of government to a council of 24 with a president at their head. The men capable of bearing arms were enrolled as a militia subject to the council. When the English government, in 1845, declared their sovereignty to extend over Natal, and sent a military expedition to take possession of the country, after some resistance the more resolute of the emigrants, under Pretorius their leader, abandoned the territory rather than live under the British rule, in which they had lost all confidence in consequence of inconsiderate interference with their titles to lands.—See "Ten Weeks in Natal," by John William Colenso, bishop of the diocese (Cambridge, 1858); McLeod's "Travels in Eastern Africa" (London, 1860); and "The Colony of Natal," by Robert James Mann, M.D. (London, 1860).

NATCHEZ, a city and the capital of Adams co., Miss., situated on the E. bank of the Mississippi river, 280 m. by water above New Orleans, in lat. 31° 34' N., long. 91° 25' W.; pop. in 1860, 6,616. It is built on the summit of a bluff, 150 feet above the water, and on the narrow strip of land between the foot of the hill and the river. The latter portion of the city, called Natchez Landing or Natchez-under-the-Hill, was formerly notorious for crime and licentiousness, but has since redeemed its reputation. It communicates with the upper quarters by broad and well graded roads. The streets of the city are regular, lighted with gas, generally gravelled in the roadway, and lined with shade trees. The houses are principally of brick, and the private residences are adorned with gardens. The brow of the bluff along the whole front of the city is occupied by a park. There are 8 churches (1 Baptist, 1 Episcopal, 1 Jewish, 1 Methodist, 3 Presbyterian, and 1 Roman Catholic), a court house and gaol, a city hospital, a U. S. marine hospital, and a number of good schools. The Natchez institute, supported by a municipal tax, comprises a primary department, a grammar school, and a high school; it is conducted by a superintendent and 15 teachers, and has 616 pupils. Two daily newspapers are published in the city. In the vicinity are the seats of many wealthy families. The business of Natchez is mainly in cotton, which is brought to this market from the adjoining counties, and in the supply of provisions and implements for the neighboring plantations. Daily steam packets communicate with New Orleans, Vicksburg, and Memphis, and a stage line connects at Brookhaven with the New Orleans and Jackson great northern railroad. The climate of Natchez is pleasant and salubrious. The winters are temperate, though

variable, and the summers are long and equable. The thermometer seldom rises above 90°.—The site of Natchez was selected by a party sent by Lemoine d'Iberville in 1700 as the chief place of a number of proposed settlements in the lower Mississippi territory, and the name of Rosalie was given to it in honor of the countess of Pontchartrain, whose husband had been one of Iberville's patrons. No settlement was made however until 1716, when Lemoine de Bienville, Iberville's brother, built Fort Rosalie on Natchez bluff. In November, 1729, the fort and adjacent settlements were destroyed by the Natchez Indians and the inhabitants massacred; but a few months later a force of French and Indian allies drove out the Natchez and rebuilt the fort, which continued to be a French military and trading post until it passed into the hands of Great Britain by the treaty of 1763. It was now called Fort Panmure. In 1779 it was occupied by the Spaniards, who kept possession of it until March, 1798, although by the treaty of 1783 it was rightfully included in the territory of the United States. In April, 1798, the territory of Mississippi was created by act of congress, and Natchez became its capital. In 1820 the seat of government was removed to Jackson. In 1840 a large part of the city was laid in ruins by a tornado.

NATCHEZ, a tribe of Indians once residing in the western part of Mississippi, near the bank of the river of that name. Each of their villages had a sacred building, sometimes dignified by the title of temple, in which were placed the fetiches of the tribe and the bones of the dead; it also contained an altar upon which burned a perpetual fire. Near by was the hut of the chief, who derived his descent from the sun, and around it were the cabins of the people, over whom he ruled with almost absolute authority. Whenever a great chief died, a number of persons of the same age were strangled to accompany him in his journey to the other world. The nation was also divided into nobles and plebeians. Except in these particulars, and the peculiarity of their language, there was nothing to distinguish them from other tribes. Historical research fails to confirm the traditional account of their greatness, the degree of their civilization, and their emigration from the south. The French in that region gradually encroached on them, and, irritated at last by their demands, the Natchez rose on the morning of Nov. 28, 1729, and murdered every Frenchman in the colony. But while rejoicing in their success, they were attacked, Jan. 28, 1730, by the Choctaws under Le Sueur, and a few days later Soubis at the head of the French troops completed the work of destruction. Part of the tribe escaped across the Mississippi river to the vicinity of Natchitoches, but their fortress could not long withstand the force sent against it. The chief and over 400 of the tribe were taken prisoners and sold as slaves, while some were incorpo-

rated with the Chickasaws and Muskogees, and others fled further west. Thus perished the nation of the Natchez, which is chiefly indebted to Châteaubriand's *Les Natchez* for the interest connected with its fate.

NATCHITOCHES, a N. W. parish of La., intersected by Red river and bounded E. by a branch, ~~the~~ line bayou; area, 2,260 sq. m.; pop. in 1853, 13,798, of whom 7,670 were slaves. It has a level surface and fertile soil, especially near the rivers. The chief productions in 1850 were 15,574 bales of cotton and 894,011 bushels of Indian corn. It contained 4 saw mills and 1 tannery, and in 1853 18 churches. Red river is navigable for steamboats through the parish.—NATCHITOCHES, the capital, is situated on Red river at the foot of a bluff, about 500 m. by water from New Orleans; pop. in 1850, 1,261. It has an active commerce, and contains a U. S. land office.

NATIONAL LEGISLATIVE ASSEMBLY, the 2d of the great representative bodies which governed France during the revolution. It sat from Oct. 1, 1791, to Sept. 21, 1792, and was preceded by the constituent assembly and followed by the national convention. Its composition was completely democratic. It embraced no partisans of absolutism and privilege, but it had three parties, the right, centre, and left. The right were strict constitutionalists, led by Dumas, Ramond, Vaublanc, Beugnot, and others, and supported by the *bourgeoisie* and the club of the Feuillants. The left were the Girondists, who were disposed to defend the revolutionary movement in every way, unlike the right, who would only defend it by the laws; their principal orator was Brissot, and their main reliance the populace. The centre was attached to the new order of things, but inclined to moderation. It was soon, however, identified with the left, which obtained the control of the assembly, and in March, 1792, succeeded in forcing Louis XVI. to accept a Girondist ministry. They passed decrees against the emigrants and the priests who refused to take the oaths to the constitution, and obtained a declaration of war against Austria; but as Louis could not conquer his dislike to them, their ministry was dismissed in June and succeeded by one formed from the Feuillants. The populace sided with the Girondists; and on June 20 a mob of 80,000 persons, after presenting a threatening petition to the assembly and upbraiding it with the disasters of the republican arms, invaded the Tuileries and subjected the king to various insults. On July 5 the assembly declared the country in danger, the citizens armed themselves, a camp was formed at Soissons, and the revolutionary enthusiasm rose to the highest pitch. On Aug. 10 the mob attacked the Tuileries, and the memorable conflict ensued with the Swiss guard, who maintained a brave defence until Louis ordered them to cease firing, when the exasperated insurgents put them to the sword. In the mean time the king had gone to the

legislative chamber, where the assembly resolved upon his suspension, and committed him to the Luxembourg, whence the commune transferred him to the Temple. Royalty was now virtually at an end, though the king's trial did not take place until the meeting of the national convention, which the assembly had resolved to call together. The Girondist ministry was restored, and the arbitrary period of the revolution was inaugurated by the supremacy of the commune over the representative assembly, and the massacre (Sept. 2, 8, and 4) of the prisoners in the Carmes, Abbaye, Conciergerie, Force, &c.

NATIONS, LAW OF. See LAW OF NATIONS.

NATRON. See SODA.

NATURAL BRIDGE. See BRIDGE, NATURAL.

NATURAL HISTORY, strictly speaking, is the history of universal nature or of all natural objects, their qualities and forces, their laws of existence, their origin (as far as possible), and their mutual relations to each other and to man. The study of the physical forces of nature, however, has been separated into distinct branches of science, under the names of natural philosophy, chemistry, astronomy, &c.; leaving for natural history proper the investigation of the structure, properties, and uses of the inanimate bodies called minerals, and of the various kinds of living things, both animal and vegetable, including their description, collection, preservation, determination, and arrangement in a natural series, and embracing as principal divisions zoology, botany, and mineralogy. For details on these divisions, see the articles ANIMAL, BOTANY, COMPARATIVE ANATOMY, GEOLOGY, MINERALOGY, PHYSIOLOGY, ZOOLOGY, and the various animal and vegetable classes in their respective order. It is principally a science of observation, its phenomena being beyond the control of experiment; by observing the same objects in the various positions and relations in which they occur in nature, the naturalist by degrees arrives at a knowledge of the general laws which regulate the phenomena and conditions of existence, and will finally be able to make out a natural classification in zoology, botany, and mineralogy. At present natural history is little more than a grand catalogue of nature's works, with here and there a satisfactory division founded on permanent and essential characters; the present systems of classification are dictionaries, as it were, in which from the known properties of the objects we seek to discover their names, instead of being, as in ordinary lexicons, directed by the names to the properties. The aim of natural history is to take the earth when it was without form and void; to notice the consolidation of its crust, with its strata of igneous origin, its layers of deposition from ocean and fresh water, its volcanic outpourings, its upheaval of mountains, its subsidence of ocean floors, its modification by flood and glacier, and the other grand phenomena of phys-

ical geology; to people the waters, the land, and the air with diverse, strange, and often gigantic forms; to clothe its surface with the rich vegetation of the carboniferous and other floras; to watch the gradual introduction of mammals and the preparation of the earth for the appearance of man, the highest of created things on this planet; and to recognize in all this the carrying out of a premeditated plan. Whether this living nature has been the result of a succession of distinct creative acts, as has been until recently believed by most naturalists, or whether, as Darwin maintains, all living things have been evolved by natural causes from a few primordial types introduced by the single primary creative act, the grand panorama of animated nature in either case suggests to the mind the idea of a plan foreseen from the beginning, and executed determinately and intelligently. The study of natural history has engaged some of the most brilliant minds from the time of Aristotle to the present day; among others Pliny, Bacon, Linnaeus, Buffon, Cuvier, Humboldt, and Agassiz. It has now assumed a place in our courses of instruction, and its teachings have important relations not only to the intellectual, but to the moral, æsthetic, and material interests of a community. Its successful cultivation requires a knowledge of mathematics, chemistry, optics, and other divisions of physics, and the higher departments enter boldly the realm of metaphysics; indeed, there is hardly a branch of human knowledge which will not find occasion for its employment in the pursuit of natural history. Its objects are infinitely diversified, and their number inexhaustible; no one need fear lest he meet with no portion of its broad domain uncultivated, for the field is immense and the laborers comparatively few; the objects are generally beautiful, and their interesting relations always present, ever increasing, and never wearisome and unprofitable. The descriptions of nature sparkle like gems in the languages of all nations, in poetry sacred and profane, ancient and modern; the most beautiful and instructive teachings of the Bible, perceptible even to childish comprehension, are illustrated by reference to the phenomena of nature. Beauty of form, proportion, and color, grace of movement, the sweetest sounds, the most delicious odors and savors, the most enchanting landscapes, and whatever is beautiful in the world about us, can only be known in perfection in the works of nature; painting, sculpture, architecture, and domestic adornment borrow their choicest ornaments from nature's portfolio, and are successful only so far as they imitate her beauty. The importance of the study of natural history in a utilitarian point of view, especially of the departments of mineralogy and geology, can hardly be overestimated in a country which contains such vast supplies of coal, iron, copper, lead, silver, gold, salt, coal oil, and other mineral resources as America; not only that they may be obtained

in the most economical manner where they exist, but to prevent the useless outlay of capital where, according to well ascertained laws, they should not be looked for. In agriculture, engineering, draining, the sinking of wells, the introduction of new plants and animals useful in the domestic and ornamental arts, and other plans and processes upon which the prosperity, healthfulness, and even the settlement of large tracts of country depend, indispensable aid is derived from natural history. Agriculture is admitted to be the great and unfailing source of national wealth, and has been defined as "natural history applied; geology, botany, and zoology are its basis, and in proportion as these are understood, will there be success."

NATURAL PHILOSOPHY, a name now very generally given to that familiar aggregation of at least 10 separate branches of natural science, the common characteristic of which is that they treat of the properties, and the laws of the phenomena, of bodies considered in the mass, or as bodies and not as substances. Chemistry, on the other hand, considers bodies as substances, or in reference to their nature and composition. The term is in itself vague and ill-chosen; but its objects and limits are perfectly defined. It evidently originated in the modern dividing into distinct sciences of a body of knowledge, most of which, except the mathematics, at one time passed under the name of philosophy. It was at first the name of the science of the material universe, as distinguished from mental science, or metaphysics. More recently, the separation of the science of organized from that of unorganized matter has taken from it the subject of physiology. Excluding, further, chemistry, and the derivative sciences, as geology, &c., that which remains, and which is now understood as coming under the term natural philosophy, is the coördination of two general subjects, mechanics and physics. For the three branches of the former of these, and its relations to other sciences, see **MECHANICS**. The recognized direct branches of physics are 7: somatology, treating of the properties and strictly molecular phenomena of bodies, acoustics, optics, magnetism, electricity, thermotics, or heat, and meteorology. Mechanics includes the cases of the action of forces on masses, from without them; physics, those of the action on masses of forces which are molecular, or which modify the physical condition of the bodies themselves. Thus, all these 10 branches of science have to do with entities of two sorts: material masses (without reference either to composition or to life), and forces. A material mass is that which has extension, impenetrability, and inertia, and hence also ponderability. A force is any energy or cause capable of moving or in any way changing such material mass. Thus, in a true philosophy, the old definitions of masses and agents, as being ponderable and imponderable matters, are abandoned. Imponderables are mere negations. But all observation shows

that energies or forces are coextensive with material masses; and that neither can nor does, in the universe as revealed through our senses, ever exist apart from the presence of the other. Faraday has recently given the key to the most exact physical conception now existing on this point, when he treats of the "forces in matter." These forces, it will readily be seen, are all susceptible of being grouped under 4 species—the mechanical, physical, chemical, and vital. Phenomena due to the first two classes belong to natural philosophy. The recognized primitive physical forces are those of molecular repulsion, cohesion, gravitation, light, actinism, magnetic and electrical forces, and heat. From the first two of these, modified by affinity, result adhesion, capillary attraction, diffusion, and osmose. Physical as well as mechanical phenomena and laws run through and help to constitute astronomy, the various sciences relating to the earth, physiology, &c. The several departments of natural philosophy, and most of the separate physical agencies, will be found treated under the appropriate titles.

NATURALIZATION, the act of investing an alien with the rights and privileges of a native-born citizen or subject. It is of two kinds, collective and personal. A collective naturalization takes place when a country or state is incorporated in another country by gift, cession, or conquest. Thus, when England and Scotland were formed into one kingdom in the reign of Queen Anne, it was declared by the 4th section of the act of union that subjects of the United Kingdom possessed thereafter all the rights, privileges, and advantages enjoyed by the subjects of either kingdom; and when Louisiana was ceded by France to the United States in 1803, it was provided by the 8d article of the treaty that its inhabitants should be entitled to all the rights and privileges of citizens of the United States; and a similar effect took place when the republic of Texas was annexed to and formed into one of the states of the American Union. There have been instances, moreover, where nations have conferred generally upon the subjects of other nations all the rights enjoyed by their own subjects. Such a privilege was conceded by France to Spain by the Bourbon family compact of 1761; and formerly in France the Dutch and Swiss had by treaty stipulations the rights of natives. Personal naturalization is where the privileges of a subject or citizen are conferred upon an individual by the license or letters patent of a sovereign or the act of a legislative body, or are obtained by the individual himself under a general law upon his complying with certain conditions prescribed by the law.—The practice of naturalizing foreigners existed among the states of antiquity, and is found in the rudest forms of human society. The North American Indians frequently adopted Europeans, and more frequently members of other tribes taken

in war. Carver, the traveller, while dwelling with the Naudowassies in 1766, was admitted a member of the tribe, and elevated to the rank of chief. In Athens, by the laws of Solon, none but those who were banished from their country for ever, and had taken up their permanent abode with their families there with the design of practising a trade or profession, could be enrolled on the list of citizens. Afterward, however, citizenship was conferred upon foreigners eminent for their virtue or talents, but was deemed so great a distinction that the proposal had to be canvassed at two assemblies of the people. If approved of at the first, it had to be ratified at the second by a vote of at least 6,000 citizens. The voting was by balloting with pebbles at the close of the assembly, and if favorable the name was inscribed upon the register of the tribes, and the cause for which the privilege was conferred was specified in a decree, which any citizen was at liberty to impugn if insufficient. Sometimes the right was granted to the inhabitants collectively of another state, by which all who crossed over into Attica became thereupon citizens. This naturalization conferred every civil and political privilege except that of holding the office of archon or priest, and in the early stages of the republic was but rarely granted even to requite the most signal services, as it was esteemed the most splendid distinction which the state could bestow, and one which the greatest merit could scarcely expect to receive. At a later period, however, it was more common, and Isocrates laments the facility with which the state threw away its nobility upon strangers. When the number of citizens had greatly diminished by war, the loss was supplied by the naturalization of aliens, large bodies of whom resided at Athens engaged in commercial and mechanical pursuits. This was done after the battle of Chæroneia; and when the disastrous defeat at Syracuse had nearly depopulated the state, the deficiency of citizens was made up by an extensive naturalization of foreigners. This was done by the vote of the inhabitants of a deme (township or ward) at its public meetings, after which the name was inscribed upon the *lexiarchic* register or roll of the qualified citizens of the deme kept by the demarch. Perhaps no state in proportion to its population ever naturalized so many aliens.—In Rome, during the republic, citizenship was conferred by a vote of the senate upon aliens who had rendered eminent services to the state, of which several striking examples are mentioned by the Roman historians. After the social or Marsic war, 90 B. C., the right was extended to all the people of Italy. Under the emperors, down to the reign of Antoninus (Caracalla), foreigners petitioning for citizenship were naturalized by an imperial decree; but under a constitution promulgated by Antoninus all the free inhabitants of the various provinces comprising the empire became thereafter Ro-

man citizens; and as that empire embraced the civilized world, there could be few or no instances thereafter of personal naturalization.—The mode of obtaining naturalization, and the conditions upon which it will be granted, differ in different countries. In the United States the power of conferring it is exclusively vested in the confederated sovereignty of the states. This power has been sometimes exercised by a collective naturalization, in cases where foreign territory has been acquired and in respect to certain Indian tribes; but the mode in which individuals obtain it on their own application is regulated by acts of congress. The policy of this country upon the subject, which is characterized by a desire to admit all foreigners of good character to a full participation in all the rights enjoyed by our own citizens, after a period of probation sufficiently long to enable them to become acquainted with the nature of our institutions, is to be traced back to an early period of our colonial history. It was not derived, like many of our laws, from the enactments or the example of Great Britain, but grew out of the necessities attendant upon the settlement of a new country. At the period when the colonies were founded, the policy of England for more than a century had been hostile to conferring political privileges upon foreigners; and so illiberal was its course in this respect through the whole period of our colonial history, that one of the acts of tyranny charged upon George III. in the declaration of independence was, that he had endeavored to prevent the population of the states by obstructing the laws for the naturalization of foreigners, and by refusing to pass others to encourage their migration hither. The only mode by which a foreigner in England could obtain naturalization investing him with all the rights of a subject was by act of parliament. He could obtain letters of denization by the king's special license, which was granted with certain restrictions. In the 7th year of the reign of Queen Anne an act was passed for naturalizing foreign Protestants, by which persons of this class could be admitted to all the rights of subjects upon receiving the sacrament and taking the oaths of abjuration and allegiance; but it was repealed in the short space of 8 years. The rights of foreigners settled in the colonies were in a very precarious state. By the law of England they could neither hold nor transmit real property, nor exercise any political rights; and by the navigation act, unless they were naturalized or made free denizens by the king's letters patent, they were forbidden to exercise in any of the colonies the occupation of a merchant or a factor. To remedy this state of things and encourage immigration, the colonial legislatures exercised the right of passing naturalization laws. Maryland was the first colony that took this course. In 1666 she enacted a law for the naturalization of the Dutch from Cape Henlopen, and the French Protestant refugees who had

settled in the colony, and continued to pass laws for the naturalization of aliens to the time of the revolution. In 1671, in the reign of Charles II., the colony of Virginia passed an act for the naturalization of any one desiring to make that commonwealth his constant residence, who might apply by petition to the general assembly; the act commenced with the declaration that "nothing could tend more to the advancement of a new plantation nor add more to the glory of a prince than being the gratuitous master of many subjects, nor any better way of producing that effect than the inviting the people of other nations to reside among them, and by a communication of privileges." Five acts were afterward passed, naturalizing a number of aliens who had petitioned for the privilege. In 1680 the governor was authorized to grant letters of naturalization to any foreigner settled in the colony upon his taking the oath of allegiance. In 1705 a law was passed, adding the test oath to the oath of allegiance to secure the Protestant succession, and in 1738 another act naturalizing any alien who might settle upon the Roanoke. In South Carolina, in 1690, the proprietors proposed to admit the French Protestants who had settled in the province to all the privileges enjoyed by others. The measure, however, was strenuously opposed by the native and English inhabitants, who insisted that it was contrary to the law of England to admit aliens to the rights of subjects, as no power but the British parliament could remove their legal disability. But the mild and patient demeanor of the new settlers gradually overcame all national antipathies, and awakened such general respect and esteem that, in 1693, the legislature of the colony with great unanimity passed a naturalization act, without even affecting to be disturbed by any scruples respecting the exclusive power of the British parliament. The colony of New York passed an act in 1683, declaring that all actual inhabitants of the province professing Christianity, of whatever foreign nation, should be entitled to all the privileges of natural-born subjects upon taking the oath of allegiance. Delaware in 1700 passed an act empowering the governor to declare any alien, previously settled or thereafter coming to settle in the province, naturalized upon taking an oath to be true and faithful to the king and to the governor of the province, and declaring that all Swedes, Dutch, and other foreigners settled in the colony before its acquisition by the English were to be deemed fully and completely naturalized. Pennsylvania also passed a naturalization law in the same year, and South Carolina in 1696. These laws were not favorably regarded in England. They were looked upon as encroachments upon the royal prerogative or the rights of parliament; and even in the colonies the more strenuous loyalists denounced them as disregarding the navigation acts, as tending to an undue increase of the inhabitants, thereby creating formidable antago-

nists to English industry and nursing a disposition to rebellion. In 1715 the colony of New York passed an act for the naturalization of all foreign Protestants then inhabiting the province. The act was referred by the board of trade to Northey, the English attorney-general, who condemned this mode of naturalizing "in the lump," but recognized the right of the legislature to naturalize particular aliens by name, after inquiring into each case specially; and thereafter down to 1778 some 14 acts were passed, by which an immense number of aliens were naturalized by name. In 1740 an act was passed by the British parliament for the naturalization of foreign Protestants settled in the colonies of America. It required a residence there of 7 years without having been absent at any time for more than two months, and all naturalized under it, except Quakers or Jews, had first to receive the sacrament of the Lord's supper in some Protestant communion. This was undoubtedly designed to supersede colonial legislation, but it did not have that effect. The long period of residence required was very objectionable in a new country, and the Catholics who had settled extensively in Maryland were excluded from its provisions. The colonial legislatures still continued to pass naturalization laws, and the difficulties growing out of the subject continued to increase until the separation of the two countries. During the revolution and until the adoption of the federal constitution, the power of naturalizing aliens was exercised by the states. The constitution of the state of New York, adopted in 1777, declared that it should be in the discretion of the legislature to naturalize all such persons and in such manner as they should think proper. The legislature enacted no general law, but continued to pass acts for the naturalization of persons by name down to the year 1790. Application was made by petition, and the names of all the petitioners whose applications were granted were included in one general act passed toward the close of each session. After the breaking out of the revolution, and especially after the independence of the United States was recognized by Great Britain, it became necessary both here and in England to determine who of those born in the colonies were to be deemed aliens. It was decided in the English courts that all persons of this class, adhering to the American government during the war and until after the treaty of 1783, ceased thereafter to be subjects of Great Britain, and were aliens; but in the American tribunals it was held that the colonies acquired all the rights and powers of sovereign states when they declared their independence on July 4, 1776, and that the people of the respective states ceased upon that day to be subjects of Great Britain, and became members of the new social compact then formed; that none were excepted unless, within a reasonable time after that event, they placed themselves under the protection and power of the government of

Great Britain in such a way as to indicate an election on their part to remain in allegiance to that country. It was conceded by the tribunals of both countries that all persons born in the colonies had a right upon the happening of such an event as the revolution to elect to which government they would adhere; the point upon which they differed being that the English courts considered the date of the treaty of 1783 as the period when we ceased to be subjects, while our courts adopted as the era the day of the declaration of independence. In some of the states laws were passed soon after the declaration of independence, setting forth that all abiding in the state after that event, or after a certain specified period, and deriving protection from the laws of the state, owed allegiance to it. This was the case in New York, Massachusetts, Pennsylvania, and New Jersey. In other states no special laws were passed, but each case was left to be decided upon its own circumstances according to the voluntary acts and conduct of the party. It was also held that persons born in Great Britain who adhered to the American cause until the close of the war, became thereby American citizens; and the natives of the colonies absent and living under the protection of Great Britain at the declaration of independence, but who returned to the country before the treaty of 1783, and continued here afterward, were held to be citizens. In Virginia it was declared by an act of the legislature that natives of any state who had borne arms against the United States during the war had ceased to be citizens of that commonwealth. The question of the alienage or citizenship of those born in the country before or during the war became a very important one, as it involved the right of succession to landed property, and was a fruitful source of litigation until ultimately settled by the tribunals of both countries. In the articles of confederation there was a clause declaring that the free inhabitants of each state should be entitled to all the privileges and immunities of free citizens in the several states; and as each state had the power of determining for itself upon what condition aliens should be admitted, and as in some of the states higher qualifications were required by law than in others, it was felt that great inconveniences would arise in the practical operation of this clause. A single state had the power of forcing into another state any alien upon whom it might confer the right of citizenship, though declared to be disqualified by the laws of that state. One state had but to naturalize him, and then, by the effect of the provision in the articles of confederation, he became a citizen in every other, thereby making the law of one state paramount to that of the rest. No actual difficulty occurred, but the most serious embarrassments were likely to arise at any moment. This inevitable conflict of jurisdictions was pointed out by Hamilton in the "Federalist," and both he and Madison strenuously ad-

vocated the necessity of a uniform rule of naturalization for all the states. Accordingly, when the federal constitution was framed in 1787, a provision was inserted without debate conferring upon congress the power of establishing one uniform rule of naturalization throughout the United States; and at the second session of the first congress after the adoption of the constitution, on March 26, 1790, an act of the most liberal character was passed, authorizing the naturalization of any free white alien after a residence of two years under the jurisdiction of the United States and of one year in the state where he applied for admission; and from that time to the year 1854 some 15 acts have been passed upon the subject. In 1795 the period of residence was increased to 5 years, and a previous declaration upon oath by the alien of his intention to become a citizen was required to be made before a court of one of the states at least 8 years before the applicant's admission. In 1798 the residence was increased to 14 years, with 5 years' previous declaration of intention. In 1802 the residence was reduced again to 5 years and the declaration of intention to 8 years; and in 1824 the declaration of intention was further reduced to 2 years. Though the power to establish a uniform rule of naturalization had been conferred by the constitution upon congress, and congress had exercised it by the enactment of a general law, still it was supposed in some of the states that they had concurrent jurisdiction. It was decided in Pennsylvania that the states still had a concurrent power of naturalizing if they did not contravene the legislation of congress. In 1790 the legislature of Virginia passed a naturalization law, differing from that of the United States. It conferred the right of citizenship upon all who came to the state with intent to reside, upon taking an oath of fidelity to that commonwealth; and provided further that any citizen might expatriate himself and become absolved from his obligations, upon making a public declaration to that effect before a court of justice and departing from the state. But it was held by the supreme court of the United States in 1817 that the power to naturalize was vested exclusively in congress. The soundness of this decision was much questioned at the time, but it is now universally acknowledged to be correct. But though no state can confer upon any alien all the rights and privileges of a citizen of the United States, it may grant him any civil or political privileges within its own jurisdiction not inconsistent with the laws of the United States; and in many, especially in the western states, aliens are allowed to hold land, to exercise the elective franchise, and to enjoy many of the privileges of citizens, a liberal policy which has contributed greatly to the rapid settlement of these states, and to their increase in wealth and prosperity. —The existing laws of the United States upon the subject of naturalization are to be gathered from many statutes, some of them relating to

other subjects; and the want of one general act, in which the whole law should be embodied and clearly expressed, has been very much felt. The qualifications requisite, and the mode of obtaining naturalization, are at present (1860) as follows. The applicant must be a free white person, and must have resided in the United States for the continued term of 5 years next preceding his admission, and one year at least within the state or territory where the court is held that admits him. Two years at least before his admission he must declare on oath or affirmation, before a court of record having common law jurisdiction and a seal and clerk, or before a circuit or district court of the United States, or before a clerk of either of the said courts, that it is *bona fide* his intention to become a citizen, and to renounce for ever all allegiance and fidelity to any foreign prince, potentate, state, or sovereignty, and particularly by name the prince, potentate, state, or sovereignty of which he is at the time a citizen or subject. This declaration is recorded by the clerk, and a certificate under the seal of the court and signed by the clerk that he has made such a declaration is given him, which is received thereafter as evidence of the fact. If the applicant was a minor under the age of 18 when he came to the country, his previous declaration of intention is dispensed with, and he is entitled to be admitted after he has arrived at the age of 21 years, if he has resided 5 years in the United States, including the 3 years of his minority, and has so continued to reside up to the time when he makes his application, upon complying with the law in other respects. There is some obscurity in respect to the latter provision in the law. Some have thought that the 3 years of minority from 18 to 21 is all that can be allowed as a part of the 5 years' residence demanded by the act, and that one naturalized as a minor was not entitled to be admitted until he had arrived at the age of 28; but it has been decided in the New York common pleas (all the judges concurring) that he is entitled to be admitted at 21, if he had resided here since he was 15; that all that the statute requires is, that he must in every case have resided here between the ages of 18 and 21, and if he has done that and also resided here 2 years before that period began, it is a residence of 5 years within the meaning of the act, and he is entitled to admission at 21. When the applicant has completed the necessary residence, he must prove the fact before one of the courts previously named by other testimony than his own oath. One witness, if he knows the fact, is sufficient. If entitled to admission without a previous declaration of intention, he must declare upon oath and prove to the satisfaction of the court that, for the 3 years next preceding his application, it was *bona fide* his intention to become a citizen; and every applicant must prove (which may be done by his own oath, unless the court should require other testimony) that he has

behaved during the period of his residence as a man of good moral character, attached to the principles of the constitution of the United States, and well disposed to the good order and happiness of the same. The mode of admission is as follows. The applicant goes to the clerk of the court and exhibits the certificate of his having declared his intention. The clerk then prepares a written deposition for the witness, setting forth his knowledge of the applicant's residence and of his good character, and another for the applicant, declaring that he renounces all allegiance to every foreign power, and particularly that of which he is a citizen or subject, and, if he has borne any title of nobility, that he renounces it, and that he will support the constitution of the United States. The parties are then taken before the judge, who examines each of them under oath; and if he is satisfied that the applicant has resided in the country for the requisite period, and is a man of good character, he makes an order in writing for his admission. The depositions are then subscribed by the parties and publicly sworn to in court in the presence of the judge; and the certificate of the declaration of intention, the depositions, and the order of the judge are filed, and constitute the record of the proceeding. A final certificate under the seal of the court, signed by the clerk, is then given to the applicant, declaring that he has complied with all the requisites of the law, and has been duly admitted a citizen, which certificate is conclusive evidence thereafter of the fact. In the case of a minor the previous declaration is dispensed with, but in all other respects the course of procedure is the same. The record of naturalization, if regular upon its face, is conclusive as to the naturalization of the alien, and cannot be contradicted by extrinsic evidence. It may be set aside, however, if fraudulently obtained, by the court where the alien was naturalized. An alien who resided in the United States before June 18, 1812, and has continued so to reside, may be admitted without any previous declaration of intention; but in that case he must prove that he resided here before that period, and continued so to reside, and by the oath of two witnesses, who must be citizens, that he has resided within the limits and jurisdiction of the United States for 5 years immediately preceding the time of his application; and the place or places where he resided during these 5 years, and the names of his witnesses, must be set forth in the records of the court. Similar provisions respecting aliens who resided here at an earlier period were enacted, but they have now become obsolete by lapse of time.—A child born out of the United States is a citizen if the father was one at the time of the birth of the child, but the right will not descend to one whose father has never resided in the United States; and the minor children of persons naturalized, if the children are then dwelling in the United States, become citizens by the

naturalization of the parent. It was formerly questioned whether this latter provision applied except to the children of parents naturalized before the passage of the act in 1802. Chancellor Kent, in his "Commentaries," inclined to the opinion that the act was prospective, and was designed to embrace the children of persons who should thereafter be naturalized, and opinions to the same effect were expressed by many eminent jurists. But the point came up for decision in the court of chancery of the state of New York in 1840, in the case of children who were minors, living with their father in this country, when the father was naturalized in 1830, and whose right to succeed to his estate was denied upon the assumption that they were aliens. Chancellor Walworth decided that they were not aliens, but became citizens in 1830 by the naturalization of their father. After an elaborate examination of the legislation of congress, he held that this provision in the act of 1802 was prospective, so as to embrace the children of aliens naturalized after the passage of the act, as well as the children of those who were naturalized before. A decision to the same general effect was rendered by Judge Daly in the New York common pleas in 1847. In 1850 the point was again raised in Arkansas in a case of much public interest. The attorney-general of the state brought a writ of *quo warranto* to test the right of one Peck to exercise the office of sheriff to which he had been elected, upon the ground that he was not a citizen. Peck relied simply upon the fact that his father was naturalized in New York when he was 11 years of age, and that he was at that time living with his father. The supreme court, after a very careful examination of the question and of the authorities, decided unanimously that Peck was a citizen. Another important question under this provision, is whether both parents should be naturalized to confer the right upon children. The importance of this question is greatly lessened in all cases of naturalization after Feb. 10, 1854, as congress on that day passed an act declaring that any woman entitled to be naturalized, then married or who should thereafter be married to a citizen, should be deemed and taken to be one; but before that time the American courts had repeatedly held that a wife who was an alien did not become a citizen by the naturalization of her husband. In the case before Chancellor Walworth, and in the one in Arkansas, the naturalization of the father was all that was shown. The attention of the court, however, was not called to the point; but in several other cases where it has been raised incidentally, very eminent judges have declared that the naturalization of the father is all that is required, and Chancellor Kent in his "Commentaries" has expressed himself to the same effect. These two questions are of great practical importance, as vast numbers of persons since the enactment of this provision have in-

herited, purchased, and transmitted real property upon the assumption that they were citizens by the naturalization of their fathers, whose rights and the rights which others have derived from them would be disturbed if a different construction were now given to this provision; and although these two questions have not been decided by the highest authority in this country, the supreme court of the United States, it may be assumed, from the decisions that have been rendered, from the concurring opinions of many eminent jurists, and from reasons of public policy, that they are now settled, and the construction above stated universally acquiesced in. If an alien who has declared his intention die before he is naturalized, his widow and children may become citizens by simply taking the oath required of all naturalized citizens to support the constitution of the United States, and to renounce all previous allegiance. In this case the period of residence of the widow and children is immaterial, nor is any distinction made between minor children and adults.—In certain cases aliens are disqualified from becoming citizens. No alien can be admitted while his country is at war with the United States, nor can one be admitted who was legally convicted of having joined the British army during the American revolution, or who was proscribed by any state before 1802, unless with the consent of the state.—By the terms of the law also none but "free white" persons can be naturalized. This is supposed to exclude all that can be denominated colored races, the copper-colored natives of America or Indians, the African races, and the yellow races of Asia. In the celebrated Dred Scott case, decided by the supreme court of the United States in 1856, it was declared that the American Indians were not citizens, but independent tribes living under the protection of the United States; that the Africans imported into this country and their descendants were not the people by whom the government of the United States was established, but a separate and subjugated race dwelling here, who were never intended to be embraced under the denomination of citizens; and that when the right of naturalization was surrendered by the states and confided to the federal government, it was supposed and meant to be confined to persons born in a foreign country under another government, and was not intended as a power to raise to the rank of citizens inferior races born here, such as Indians, negroes, and mulattoes. Upon this latter point the judges differed in opinion, but all of them appear to have conceded that under the existing act of congress none of this class can be naturalized. Indians, however, have been admitted to the rights of citizenship by special treaties. This was done by art. 14 of the treaty with the Choctaws of Sept. 27, 1830, and by art. 12 of that with the Cherokees of May 23, 1836; and in the treaties by which Louisiana, Florida, and California were acquired, members of

the mixed Indian and African races became citizens. In the case of the mixed races a delicate and very difficult question arises as to the degree of mixture or shade of color that will disqualify. In several of the states one having African blood in the degree of one fourth is not regarded as a white person. This appears to be the case in Virginia, Indiana, North Carolina, and Kentucky. In Alabama, persons descended from negro or Indian ancestors to the fourth generation are not considered as white, even though one ancestor in each generation may have been white; but it has been held in that state that the offspring of a white mother by a mulatto father is neither a negro nor a mulatto. In Georgia and Louisiana, if the admixture does not exceed the proportion of one eighth, the person is white; and this was the rule in the *code noir* of France. In South Carolina, a distinct and visible admixture of negro blood is sufficient to disqualify, and this is to be determined upon the evidence of features, complexion, and parentage. In Ohio, persons nearer white than black, that is, all having more than one half white blood, are deemed white. No general rule therefore exists on this subject; and a man either one eighth or one fourth of African blood, who in South Carolina and Georgia would be deemed a mulatto, might be regarded by the courts of Ohio as of the white race, and entitled to be naturalized. In Wisconsin, civilized persons of Indian descent, not members of any tribe, enjoy the same political privileges as white citizens; and in the courts of California it has been held that a Chinese is not a white person within the meaning of the act of congress, and cannot be naturalized.—The residence required by the naturalization laws is a permanent abode in the country; and when that is established or begun, it will not be affected by a temporary absence upon business or pleasure, if the intention to keep up the residence here and return has always existed, and no residence has been established elsewhere. Formerly the words of the statute were: "without being at any time during the said 5 years out of the territory of the United States;" but this very stringent and absurd provision was repealed in 1848. A man's residence may be defined to be the place where he abides with his family, or abides himself, making it the chief seat of his affairs and interests. In the case of seamen, they are assumed to have complied with the conditions of the law if they have sailed exclusively in vessels belonging to the United States for the continuous period of 5 years, and have continuously shipped at least for the period of one year out of some port of the state where the court is situated in which they are naturalized. This is the established practice of the courts of the city of New York, where large numbers of seamen are naturalized annually.—On the question of the right of a naturalized citizen to expatriate himself and renounce his al-

legiance to this country, there is diversity of opinion. The more recent opinions are, that he may if he changes his domicile. (See *ALIENS*.) It was held in New York that he could not expatriate himself if he continued to reside in this country. The case was that of an Englishman naturalized here, and who, being afterward appointed consul for Spain for the port of New York, took an oath of allegiance to the king of Spain and claimed to be a Spanish subject. It was held that he remained subject to the duties and obligations of a citizen of the United States.—No statistics are preserved of the number of persons naturalized annually in the United States. Some idea of the extent to which the right has been conferred, may be formed from the number of persons naturalized in the city of New York. During 10 years, from 1850 to 1860, the number admitted in the superior court and court of common pleas, the two tribunals where nearly all applications are made, has been over 60,000. The largest numbers have been admitted in the years of the presidential election. The statistics of the court of common pleas for the last 5 years are as follows: 1855, 3,200; 1856 (presidential year), 6,684; 1857, 5,580; 1858, 3,110; 1859, 2,880.—In Great Britain, prior to 1844, naturalization could be effected only by act of parliament. Originally it conferred all the rights of a natural-born subject, but by an act dictated by the jealous policy of the government upon the accession of the house of Orange, passed in 1701, it was declared that no one, though naturalized, should be of the privy council or a member of parliament, or hold any office civil or military, or be allowed to receive any grant of land from the crown. It was of course within the power of parliament to grant these privileges specifically in any act, but it was declared that no bill should be received in either house without this disabling clause. As before stated, the king might grant letters of denization conferring certain limited rights, in the exercise of his royal prerogative. This practice existed as early as the reign of Henry II. That monarch granted charters of denization to particular persons of Irish descent, conferring upon them and their posterity all the privileges of English subjects. A great number of these charters were granted to this class of persons afterward, and appear to have been very easily obtained. The Norman rule had so paralyzed the industry of England, that Edward III., in the beginning of the 14th century, encouraged German and Flemish artisans to settle in the country. Companies consisting for some time wholly of foreigners, who were known as the merchants of the staple, carried on the trade in wool; and Italian companies, known as the Lombards, managed and monopolized the trade of the East. To all of this class special privileges were granted, either by charter or by letter of denization, which, it would seem from the preamble of an act passed in the reign of

Henry VIII., made them as free as Englishmen born within the king's dominion. Though contributing greatly to the wealth and prosperity of the country, they were always regarded by the body of the people with great jealousy; and the popular clamor against them and their privileges reached in the reign of Henry VIII. to such a height as to break out in formidable riots, and cause a total change of policy on the part of the government. Laws were enacted imposing restrictions and burdensome duties upon foreigners. In the reign of James I. there was a great influx of foreigners from the Low Countries, and the king was urgently petitioned to adopt exclusive measures against them. He acquiesced to some extent; but so far from sympathizing with the petitioners, he curtly referred to the industrious habits of the strangers as something from which his people might take example. In the reign of Charles II. the policy of the government became more liberal, and an act was passed inviting aliens to settle in the country, and engage in certain trades, with an offer of the privileges of native-born subjects; and in the reign of Anne, as before remarked, an act was passed for the naturalization of all foreign Protestants, commencing with the preamble: "Whereas the increase of a people is a means of advancing the wealth and strength of a nation;" but the clamor against it was so great, especially on the part of the city of London, that it was repealed in 1711 by an act with a counter preamble, declaring the inconveniences and mischiefs it had produced to the discouragement of the natural-born subjects of the kingdom, and to the detriment of its trade and wealth. The practice of granting letters of denization however continued during all this period, but the privileges were more limited. A denizen was, in fact, in a kind of middle state between an alien and a naturalized subject. He could not take lands by inheritance, nor enjoy any immunity in foreign trade, until after he had resided 7 years in Great Britain; and was subject to the same restrictions as to holding office, &c., as naturalized subjects. An exception was made in the reign of George II. in favor of seamen. Any foreign seaman serving thereafter for two years, in time of war, in a British ship, became thereby a naturalized subject. In this state the law remained until the reign of Victoria. Great desire having been expressed for more liberal enactments, a law was passed in 1844, defining the privileges of aliens upon some questionable points, and providing for the naturalization of all aliens residing in or coming to Great Britain with intent to settle. By the provisions of this act any alien may address a petition to the secretary of state for the home department, stating his age, profession, or occupation, the period of his residence, and the ground upon which he desires to be naturalized. The secretary of state is required to investigate the circumstances of each case, to receive all such evidence as may be offered, or as he may desire, and if he think it fit he

may grant the applicant a certificate admitting him to all the rights and capacities of a natural-born subject, except the capacity of being a member of the privy council or of parliament, upon his taking the requisite oaths; and the secretary may add any other restrictions he thinks proper. The applicant must then take the oaths of abjuration, supremacy, and allegiance, before one of the judges of the higher courts or before a master in chancery, and within 60 days thereafter the certificate must be enrolled in the court of chancery. The original certificate, after being enrolled, is duly certified by an officer of the court and returned to the applicant as the evidence of his naturalization. Before the act of 1844 the number of persons naturalized was about 8, and the number who obtained letters of denization about 25 annually. In 1847 a law was passed declaring that the act should not apply to any of the British colonies, and expressly recognizing the right of the colonial legislatures to enact their own laws upon the subject. The act of 1844 was also modified in 1858, so as to enable Jews to take the oath; and an act was passed in 1848, empowering the secretary of state or the lord lieutenant of Ireland to order any alien not a resident for three years to quit the nation, but it was of temporary duration.—The policy of France upon this subject has been restrictive, which may be traced to the unfavorable influence exercised by foreigners at various periods of her history. Many Italian adventurers were naturalized in the reign of Charles VIII., but their characters were so worthless that their certificates of naturalization were annulled by his successor Louis XII. in 1499. At the time of the league great numbers of naturalized Spaniards and Italians mingled in public affairs, and gave such offence, especially as a branch of the clergy, that a law was passed in 1579 prohibiting foreigners from holding ecclesiastical offices. Their participation in the civil administration of the state reached its climax when the notorious Italian Concini, the *protégé* of Maria de' Medici, became a marshal without ever having drawn a sword, and minister, ruling with capricious insolence a people of whose laws he was wholly ignorant. After his tragical end an act was passed in 1629, debarring foreigners from holding a seat in the administration; and the mischief wrought by Mazarin and his foreign camarilla led to a still more stringent law in 1651. No material change took place until the revolution, when in 1791 the legislative body was authorized to naturalize foreigners upon the condition that they fixed their residence in the country, and took an oath of allegiance. In 1798 a law was enacted admitting all to the rights of French citizens domiciled in the country one year, over the age of 21, who supported themselves by their labor, or acquired property, or who should marry a native, or adopt a French infant, or support an aged person, and all others whom the legisla-

tive body regarded as meriting well of humanity. In 1798 a residence of 7 consecutive years was made necessary; and as the country gravitated toward monarchy in 1800, the residence was extended to 10 consecutive years. In 1808 the residence was reduced to one year, if the alien had rendered important service to the state by his talents, inventions, useful industry, or by forming large establishments therein. In 1808 it was provided that naturalization upon the ground of important services to the state, thereafter known as *la grande naturalisation*, should be conferred by a decree ratified by the council of state. In 1814 it was declared that no naturalized subject should be eligible to a seat in the legislative chambers unless he had received the grand naturalization. After the revolution of 1848, the term of residence was reduced to 5 years; but in the following year, 1849, the previous legislation was re-established. As the law now stands, the grand naturalization after a residence of a year, in the cases already mentioned, is conferred by a decree of the emperor, ratified by the senate and the *corps législatif*. In other cases the alien must be of the age of 21, must have resided in France for 10 consecutive years, and must have declared his intention of fixing his residence there. A child of foreigners born in France, or the child of French parents born abroad, may reclaim the rights of citizenship in a year after he arrives at his majority, if he resides in France and declares his intention of there fixing his domicile, or if, residing abroad, he makes a similar declaration and establishes himself in France within the year that he makes his declaration. A foreign woman marrying a native becomes a French subject, and a French woman marrying a foreigner follows the condition of her husband; but becoming a widow, she recovers her nationality if living in France, or if she returns to it with the authority of the emperor and declares her intention of fixing there her residence. A foreigner living in France enjoys the same civil rights that are accorded to Frenchmen in the country to which the foreigner belongs. Citizenship is lost by naturalization elsewhere, by accepting office under another government without the authority of the emperor, or by so establishing one's self abroad as to indicate an intention not to return; but dwelling abroad for commercial purposes does not have that effect. Citizenship may be recovered by renouncing the foreign office and domicile, on due application to the state, upon declaring an intention to fix a residence in France and renouncing all distinctions contrary to its laws. A difference is recognized since 1823 between letters of naturalization and letters of nationality, the first conferring a new right, the latter merely restoring a right that was lost or in abeyance. All Frenchmen, whether naturalized or holding office abroad with the consent of the emperor, who are taken bearing arms against France, suffer the penalty of death; it constitutes no exemption that

they were serving in obedience to the laws of their adopted country. Not only in this provision, but upon naturalization of foreigners generally, the policy of the government is in practice very illiberal, and but few comparatively are naturalized.—In Belgium naturalization is granted by a legislative act. It is of two kinds, grand and ordinary. The first is conferred only where eminent services have been rendered to the state, and the person to whom it is granted is placed in every respect upon an equality with a native. The second naturalization, *ordinaire* or *petit*, admits to every privilege except the exercise of those political rights which are reserved for the grand naturalization. In contradistinction to France, the policy of the government on this subject is distinguished by great liberality. In Holland, by the fundamental law of 1848, a foreigner can be naturalized only by an act of the states-general, approved by the king. In neither Holland nor Belgium is any stated period of residence demanded, or any other special condition required, and citizenship in both may be lost for the same causes as in France, and restored in the same way.—In Sweden, by a law passed in 1858, an application must be made by petition to the king, accompanied by proof of the age of the petitioner, his religion, his native country, the time of his immigration, the places where he has resided in Sweden, and his general good conduct. He must be 21 years of age, of good character, a resident of Sweden for 8 years, must have the means of supporting himself, and must not be of the Roman Catholic religion. If he has been previously admitted into the service of the state, or is known as a man of more than ordinary ability in the arts or sciences, or in the industrial pursuits of agriculture or mining, or if for other reasons it is considered that his adoption as a Swedish subject would prove useful to the state, the 8 years' previous residence may be dispensed with. If all these conditions are duly proved to the satisfaction of the authority to whom his application may be referred by the king, he may be naturalized upon taking the oath of allegiance; and if a native of a country which does not admit a renunciation of allegiance, he must in taking the oath renounce in writing all rights and political privileges he possessed in his native country. In Norway naturalization is granted by the *storting*, the national legislative assembly, in which this power is exclusively vested, the assent of the king in this case not being necessary.—In Denmark a petition must be addressed to the president of the *rigsraad*, the council of state under the constitution of 1857, with a certificate of two citizens that the petitioner has resided one year in the country. An act is then passed by the *rigsraad*, declaring that the petitioner may reside and trade in the kingdom with all the rights and subject to all the duties of a native-born subject. It must be approved by one of the ministers and receive the sanction of the

king. The privilege is almost invariably granted as a matter of course whenever applied for.—In Russia naturalization is effected by taking an oath of allegiance to the emperor before an officer of the administrative department; but naturalized strangers may at any time renounce their naturalization and return to their country.—In the states of the Germanic confederation, there is a provision in the federal constitution of Vienna of 1815, by which the citizen of one German state is entitled to reside in another and do business, free of annoyances from the police or authorities, if he has ample means to live in his new residence, without becoming a burden upon his fellow citizens, and is a man of good character, against whom no criminal or civil proceeding is pending, which must be duly certified. In any one of the states he may be naturalized, as a general rule, if his own government has released him from his allegiance or allowed him to emigrate, if he has discharged all his obligations in his own state, such as paying his debts and fulfilling his military duty, and is of good character. The same conditions apply in the case of aliens from other countries, except that they are not required to show that they have fulfilled all their duties in their native country. Application must be made in writing to the council of the city or village where the applicant resides, showing that he comes within the above requirements. His petition is closely scrutinized, and if favorably regarded it is sent with the report of the council to the highest authority in the state, and a diploma is transmitted signed by the minister of the interior, and given to the petitioner upon the payment of a trifling charge. If the petition is unfavorably regarded by the council, it is sent back with notice that it is denied without assigning any grounds, but the reasons may be learned upon application. An appeal may be taken to the provincial government, but is of little value, as the decision of the local authorities is almost invariably affirmed. In Austria a foreigner acquires the rights of citizenship if employed as a public functionary, but not by mere admission into the military service, nor by receiving a title of distinction or honor, but is treated as a citizen if maintained by the government on account of military services. The right may be conferred by the superior authorities upon an individual after 10 years' residence without interruption, upon proof of the fact and upon taking the oath of allegiance. The authorities, however, may grant it before the expiration of that period upon proof of good moral character and of the applicant's ability to support himself; and foreigners acquire the rights of citizens by entering into business requiring a permanent residence. In the country the temporary possession of a farm, however, of a house or other real estate, or the mere establishment of a manufactory, or a commercial business, or a partnership, does not confer the right. Citizenship is forfeited by emigration. Marriage

with an Austrian confers citizenship upon the wife. In Prussia, by a law of 1842, the superior administrative authorities are empowered to naturalize any stranger who satisfies them of his good conduct, certain exceptions being made with regard to Jews, minors, persons incapable of disposing of themselves, and subjects of other states of the Germanic confederation. As in Austria, citizenship is acquired by nomination to a public office, or by the marriage of a foreign woman with a Prussian, and lost by emigration or accepting office in foreign states. In Bavaria, by the law of 1818, citizenship is acquired by the marriage of a foreign woman with a Bavarian, by a domicile taken up by one who gives proof of his freedom from personal subjection to any foreign state, after a residence of 6 years, and by royal decree; and it is lost by citizenship in a foreign state without special permission, and by emigration. In Württemberg it is obtained by appointment to office, or by acquiring landed property in or near the city or commune where the foreigner has, with the consent of the local authorities, established his residence. He can then apply to the government for the *Staatsbürgerrecht*, which confers all the privileges and subjects him to the obligations of a native. He may fill any office if he is of the Christian religion. Citizenship is lost by accepting office in a foreign state and by emigration. In Hanover the conditions are 5 years' residence in a commune with the approbation of the mayor or bailiff, an irreproachable character, and sufficient means of subsistence; or the right may be obtained by the purchase of a residence or a freehold in any commune, or by the consent of the state, or by holding office under government. A foreign woman married to a native, or a foreign child adopted by one, becomes a subject. In Saxony it is necessary to have had a domicile in a district for 5 years with the consent of the local authorities, or to have owned real property for that period, or to have obtained the freedom of a city; and the alien must have resided in the district, or upon his property, or in the city conferring its freedom, for 5 years.—In the Hanseatic towns but few conditions are imposed. In Bremen resident foreigners of good character are admitted to citizenship upon the payment of \$40; and if the foreigner intends to settle as a master mechanic he must be admitted a member of the appropriate guild. If he designs to engage in commercial pursuits, a payment of about \$400 is required. In Hamburg all who take up their residence, except Jews, are admitted upon the payment of a moderate sum. To do business, however, it is necessary to be a member of some guild. In Lübeck persons of good character, who have the means of supporting themselves, may become citizens after residing sufficiently long to indicate an intention to fix there their permanent residence. In Frankfort-on-the-Main citizenship is conferred for public service, and other-

wise obtained if the government is satisfied as to the good character and ability of the person to support himself. When admitted in any of these free cities, the citizen's or burgher's oath is taken, equivalent to an oath of allegiance.—In Switzerland every man, even a native, is regarded as a vagrant or a man without a home, and chased from canton to canton, unless he is a citizen of some commune. This citizenship is obtained upon the payment of the requisite fee into the treasury of the commune. In the case of foreigners, naturalization is granted by the legislature in some cantons, in others by the executive. No period of residence or qualification is necessary, but the cantons are jealous of foreigners and disposed to be exclusive. In the aristocratic cantons it is almost impossible for any but a wealthy man to obtain naturalization. In Ticino full citizenship is not obtained until 5 years after naturalization; but in Bern, Vaud, Zurich, Geneva, and most of the cantons, it is conferred when the alien is naturalized. A citizen of any community of one of the cantons is on an equal footing with those of any other canton. He may reside, do business, and enjoy every civil and personal right, but not political rights.—In Portugal an application must be made to the king through the secretary of foreign affairs, which is referred to the council of state. The applicant must be over 25 years of age, have resided in the country two years, and have the means of subsistence. The residence for two years is dispensed with upon proof that he has married a Portuguese, or been useful to the state by embarking in commerce, improving any branch of the arts, or introducing any new trade, manufacture, or invention, or by opening or improving a public road; and they are generally dispensed with in the case of mariners, as it has been the constant policy of Portugal to encourage foreigners to enter and augment its marine.—In Spain, by the ancient law of the realm, no foreigner could be naturalized. The constitution of 1837, however, included in its classification of Spanish subjects those who should receive letters of naturalization, and provided for the enactment of a law declaratory of the conditions upon which such letters would be granted. The present state of the law appears to be unsettled or difficult to ascertain. All that can be gathered is that 5 years' residence is necessary, that the applicant must be of the Roman Catholic religion, and that the right of a Spanish subject to renounce his allegiance is recognized by law.—In Sardinia any person who has resided in the country 5 years, and has purchased real estate or engaged in a useful commercial business, may apply to the minister of justice to be naturalized. The application is referred to the councillors of state, and if they report favorably letters of naturalization are granted, which must be signed by the monarch. These conditions must be complied with in every case; even the king has no power to dispense with them. In the Papal States, the pope may naturalize any

person he thinks proper. It is a power, however, but rarely exercised. The usual course is to grant it after 5 years' residence, in cases where the applicant has purchased real estate, or has engaged in some useful commercial business. In the Neapolitan dominions, previous to the changes consummated in 1860, the king, as in the Papal States, naturalized whom he thought proper; but the exercise of the power was very unusual. The general mode was the same as in the Papal States. In Naples and the Papal States none could be admitted but Catholics; but in Sardinia no distinction is made on the ground of religion. The policy of the several Italian states and the disposition of the people are averse to naturalizing foreigners. Every case, even in Sardinia, is closely scrutinized. In 1850, in consequence of extensive emigrations into Sardinia from Lombardy, Naples, and the Papal States, a special act was passed dispensing with the qualification of residence in respect to this class of Italians; but the law has since been repealed. In the republic of San Marino, naturalization is granted without residence on the payment of \$10, the republic engaging to give protection for three weeks to any naturalized citizen taking refuge there.—In Greece the policy of the government has been absurdly restrictive. The course pursued with respect to the disposition of the public lands, and the immigration and settlement of the Greeks of the islands and the Turkish provinces, has been such that no encouragement has been held out to this large body of the Hellenic family to quit the miserable and tottering empire in which they have been so long oppressed. The consequence has been that the population of the kingdom is at present but little over a million, when it might have been two or three millions under a liberal system. The 8d article of the constitution of 1848 defines citizens (*πολίται*) to be those who have acquired or may acquire the characteristics of a citizen according to the laws of the kingdom; and the national assembly that formed the constitution passed a decree, to be of the same force and effect as if incorporated in that instrument, by which it was declared that the government should neither retain nor appoint to places in the public service those who were not embraced in the following classes: 1, the native inhabitants of the Greek state, and those who took part in the struggle for independence to the end of 1827, or who came to Greece and remained there until the end of that year, and those who took a military and decisive part in battles with the enemy by sea or land up to 1829; 2, those inhabitants and combatants of continental Greece or of the islands, who took up arms in the war of independence, and who up to 1837 came and established themselves in one of the demes (districts) of the kingdom; and the descendants of the above classes. Those who established themselves in the kingdom between 1827 and 1838, are declared eligible in two years after the publica-

tion of the constitution of 1848; those who established themselves between 1832 and 1838, after 8 years; and those from 1837 to the end of 1848, the period of the framing of the constitution, after 4 years. In addition to this, by a law subsequently passed, a Greek by birth, though not a native of the kingdom, who possesses a property qualification of 100,000 drachmas (equivalent to \$16,000, a large fortune for Greece), may be elected a member of the *Bουλὴ* (chamber of representatives) if he has resided 6 years in the country, and 3 years in the province for which he is chosen. The number of those not of the Greek race in the kingdom is exceedingly small, and we are not informed whether there has been any legislation by which they can acquire the privileges of citizens.—In Turkey the population are divided into two great classes, the Turks or Mohammedans, the ruling race, and the *Rayas*, denominated "the flock," who with the exception of some few tribes are Christians or Jews. The *Rayas* are organized in distinct communities, having their own municipal regulations, as Armenians, Bulgarians, Bosnians, Servians, Latin Christians, or Jews, under a recognized head, as a bishop, patriarch, or other ruler, who is responsible to the sultan for the good conduct of his community. Resident foreigners may become members of one of these communities with the consent of the body, upon giving due notice to the Porte, and when admitted are entitled to the privileges and bound to the obligations of Turkish subjects. Foreigners, not members of one of these communities, are aliens and under the protection of their respective consuls. The Mohammedans enjoy greater privileges than the *Raya* communities, and foreigners of whatever creed or nation may be received into this class upon embracing Mohammedanism. Their naturalization is both a civil ceremony and a religious rite. It consists in going first to the Porte or the executive authority representing it, in putting on the fez cap, and making a public declaration of faith in the words: "There is no God but God, and Mohammed is his prophet;" and then repeating the same ceremony in the mosque. Circumcision is also a condition; and when the ceremony is gone through, the proselyte is invested with all the rights of a native-born Mohammedan subject. In Egypt, Persia, and throughout all the Mohammedan countries, naturalization is effected in the same way, either by embracing Mohammedanism or by being formally admitted a member of one of the other organized communities.—In the European states, with but a few exceptions which have been mentioned, a naturalized foreigner enjoys every civil and political right, and may hold the highest office. In all of them naturalization is a thing of rather unusual occurrence, the number of foreigners who become permanent residents in any one of them being very limited. Those who do are chiefly devoted to commercial pursuits; and as natu-

ralization, as a general rule, is not essential to enable them to carry on trade or commerce, it is but rarely applied for.—In the different West India islands belonging to European powers, the authority to naturalize is generally vested in the sovereign or regulated by a local law. In the island of Cuba, by the Spanish ordinance of Oct. 21, 1817, the captain-general may grant letters of license for domiciliation to all resident foreigners, upon their taking an oath of fidelity and submission to the law. These letters entitle them to hold real and personal property, and to the same protection in their person and property as Spanish subjects; but for the first 5 years of domiciliation they cannot engage in trade, open a shop, or become owners of ships or vessels, unless in partnership with Spanish subjects. After 5 years of domiciliation they can become naturalized. They must present their original letter of license to the captain-general, and avow their intention to make the island their perpetual residence; and if it appear after due inquiry by the government that they have resided constantly on the island for 5 years, and are of good moral character, letters of naturalization are granted to them after they have sworn fidelity to the Roman Catholic religion, to the crown, and to the laws, and renounced all foreign allegiance to and every privilege received from any other government. When thus naturalized, they and their legitimate heirs and descendants acquire all the rights and privileges, and are placed upon the same footing as natural-born subjects. The provision, however, in respect to naturalization, though still in full force, has become practically a dead letter, as natives enjoy but few privileges which resident or domiciled foreigners do not possess.—In Hayti, by a modification of the civil code adopted in 1860, any person who in virtue of the constitution wishes to become a citizen must within a year after his arrival make an oath before a justice of the peace renouncing allegiance to every other government, upon presenting an official attestation of which at the office of the president of Hayti, he receives from that officer an act recognizing him as a citizen of the republic.—In Mexico two years' residence is required, and one year's previous declaration of intention. This declaration is in the form of a petition to the *ayuntamiento* of the place where the applicant resides. Before he can be naturalized, the applicant must prove before the nearest circuit judge that he is of the Catholic religion, and has a trade, profession, or income sufficient to support him. The documents containing this proof must then be laid before the governor or political chief of the district or territory, and, if satisfactory, letters of naturalization are granted by that officer to the applicant upon renouncing his former allegiance and swearing to support the constitution. Colonists who settle new lands can be naturalized a year after they have settled, and aliens in the naval service upon taking the oath of allegi-

ance. The right is lost by accepting office or by becoming naturalized in a foreign country. —In Brazil 3 years' previous residence is requisite, after which naturalization is effected by a joint resolution, which must pass both chambers of the general assembly and be affirmed by the emperor. By a law passed in 1860 children of foreigners born in Brazil have, during their minority, the political condition of their parents; but on reaching their majority they acquire the rights and become subject to the duties of Brazilian citizens. A Brazilian woman marrying an alien follows his condition, but upon becoming a widow is considered a Brazilian subject if residing in Brazil, or if, returning there, she declares her intention to fix her residence in the country; and a foreign woman marrying a Brazilian has the political condition of her husband. In Peru and in Chili 5 years' previous residence is necessary; but where an alien has married a native, this period is reduced to 4 years. —In the states of Central America the more general rule is, as in Brazil, to naturalize the alien by a legislative act. In Costa Rica an application must be made to the president of the republic, accompanied by proof that the petitioner has resided there 6 years, of his good conduct during that period, and of his having honest means of subsistence. Letters of naturalization are then granted him by the president on his renouncing his previous national allegiance. In Honduras foreigners are naturalized by acquiring real estate and a residence of 4 years; but if one marries a Hondurian wife this period is reduced to 2 years, or a letter of naturalization may be obtained from the legislature for services rendered to the state, for an important improvement in agriculture or the arts, or for introducing a new manufacture in the country. In San Salvador they are naturalized by acquiring real estate and a residence of 5 years, or by contracting marriage with a Salvadorian woman and a residence of 3 years, or by obtaining a letter of naturalization from the legislative body in the same way and for the same causes as in Honduras. In most of the states of Central America naturalization is granted by the legislature to resident foreigners generally upon application without insisting upon any conditions; the clause that it is upon the ground of important services to the state, &c., being usually inserted in the letters of naturalization as a mere matter of form.

NAUDÉ, GABRIEL, a French bibliographer, born in Paris in 1600, died in Abbeville in 1653. He studied medicine at Paris, and was for some time physician to Louis XIII. Afterward he spent some time at the university of Padua, where he obtained a diploma as doctor of medicine; and subsequently he officiated as librarian of several cardinals in Rome and of Mazarin in Paris. Queen Christina appointed him in 1652 royal librarian at Stockholm, but he was compelled to leave Sweden on account of his health, and died on his homeward jour-

ney to France. He was a scholar of extensive erudition, and collected a great number of rare books and MSS. His *Bibliographia Politica* (Venice, 1638) was translated into French in 1642. He wrote a number of other works, chiefly on political and bibliographical subjects. A collection of anecdotes from his table talk was published in Amsterdam in 1708 under the title of *Naudiana*.

NAUMANN, JOHANN FRIEDRICH, a German ornithologist, born in Ziebigk, near Köthen, Feb. 14, 1780, died in Köthen, Aug. 15, 1857. His father was Johann Andreas Naumann, a well known ornithologist, and the son, after attending school at Dessau from 1790 to 1794, returned home and devoted himself to the study of agriculture, botany, geology, and ornithology. Later he turned his attention wholly to the last named science, especially to the study of the birds of Germany, and embodied his observations in a work entitled *Naturgeschichte der Vögel Deutschlands* (18 vols., Leipsic, 1822-'47), embellished by plates, a large number of which he himself engraved; and he was the author of many other ornithological works. He is considered the first of German ornithologists, and the German ornithological society named their journal from him *Naumannia*.

NAUMANN, JOHANN GOTTLIEB, a German composer, born in Blasewitz, near Dresden, in 1741, died in Dresden, Oct. 28, 1801. When 18 years of age he went to Italy, and afterward settled in Venice, where he remained 8 years teaching and composing music. In 1765 he returned to Dresden, and was appointed composer to the elector of Saxony. Shortly after he made a second journey to Italy, returning in 1769 to compose the opera of *Clemenza di Tito* for the marriage of the elector. In 1779 he made a third journey, and resided 2 years at Rome, where in 18 months he composed 5 operas. In his later years he composed much church music. —KARL FRIEDRICH, a German mineralogist, son of the preceding, born in Dresden, May 30, 1797. He was educated at Freiberg, Leipsic, and Jena. After graduating at Jena he returned to Freiberg to hear the lectures of Mohs on mineralogy, made a scientific journey to Norway in 1821 and 1822, and embodied his observations in a work entitled *Beiträge zur Kenntniss Norwegens* (2 vols., Leipsic, 1824). In 1826 he succeeded Mohs in the chair of crystallography in Freiberg, and in 1835 was also appointed professor of geognosy. This position he held till 1842, when he went to the university of Leipsic as professor of mineralogy and geognosy. He has written much on subjects connected with his profession.

NAUMBURG, a fortified German town, in the Prussian province of Saxony, situated on the Saale, near the junction of the Unstrut, 28 m. S. S. W. from Halle; pop. about 15,000. It is an active manufacturing and commercial town, but the once famous fair of Naumburg has lost its importance. Among the principal public buildings are the cathedral, remarkable

for its lofty towers and double choir, and the church of St. Wenzel with a famous picture of Cranach. An annual children's festival is celebrated here, in commemoration of the raising of the siege by the Hussites under Procopius, which according to tradition took place July 28, 1482, in consequence of the entreaties of the children of Naumburg. This event has been dramatized in Kotzebue's *Die Hussiten vor Naumburg*, but its authenticity has been called in question by recent historians. Several treaties were concluded at Naumburg in the 15th and 16th centuries, and the town was of great strategical importance during the 80 years' war and the wars of 1806 and 1818.

NAUTILUS, a name applied to both the tetrabranchiate and dibranchiate orders of the cephalopod mollusks. In the former the true or pearly nautilus is the best known species of the only living genus representing the extinct chambered shells (such as ammonites, orthoceratites, turritiles, &c.) which abounded during the primary and secondary geological ages; in the latter belongs the nautilus of the ancients (the paper nautilus of the moderns), more properly called argonaut. For the characters of the class and orders see MOLLUSCA.—The genus *nautilus* (Linn.) has a discoid, symmetrical, univalve shell, with simple aperture, sutures, and siphuncle. The organization of the pearly nautilus (*N. pompilius*, Linn.) was first made known in Prof. Owen's celebrated memoir in 1832; and afterward by Gray, Grant, De Blainville, Valenciennes, and Huxley, the last in the "Proceedings of the Linnean Society of London," vol. iii. No. 9, for Aug. 1858. The posterior portion of the body, containing the viscera, is soft, smooth, and adapted to the anterior chamber of the shell; the anterior is muscular, including the organs of sense and locomotion, and can be retracted within the shell; the mantle is very thin behind, and prolonged through the calcareous tube of the occupied chamber as a membranous siphon, and through all the divisions of the shell to the central nucleus; on the upper part of the head is a broad triangular muscular hood, the back part excavated for the involuted convexity of the shell, protecting the head when retracted, and used as a foot for creeping at the bottom of the sea with the shell uppermost. On each side of the head are 20 perforated digitated processes of a conical form, each containing a long finely ringed tentacle, whose inner surface is closely set with narrow transverse plates; the eyes, large and prominent, are placed on short pedicels on the side of the head behind the digitations; the subocular processes have no tentacles, and are rudimentary external ears, their cavity extending to the auditory capsule. The mouth has 2 horny mandibles, like the beak of a parrot reversed, the lower overlapping the upper, moving vertically, and implanted in thick muscular walls; the surrounding circular fleshy lip has 4 labial processes, each pierced by 12 canals, contain-

ing each a small retractile tentacle, making, with the 38 digital and 4 ophthalmic, 90 tentacles on and around the head. The internal cartilaginous skeleton is confined to the lower surface of the head, a part of the cephalic nervous system being protected in a groove on its upper surface, and the 2 great muscles which fix the body to the shell are attached to it. The funnel is very muscular, and is the principal organ of free locomotion, the animal being propelled backward by a succession of jerks occasioned by the reaction of the ejected respiratory currents against the surrounding water. The capacious crop opens into an oval muscular gizzard; the intestine terminates in the branchial cavity near the base of the funnel; the liver is bulky, and the bile is derived from arterial blood; there is no ink gland. Sea water is admitted into the pericardium; the branchiæ are 2 pairs, without branchial hearts, the larger branchia supporting 48 vascular folded plates on each side, the smaller 36; the large veins near the heart have clusters of follicles attached to them, according to Owen seeming to be homologous with the so called renal glands of lower mollusks; by some they are considered as diverticula to relieve the circulation during the varying pressures to which the animal is subjected. The tongue is furnished with numerous papillæ and spines. The nautilus, though the lowest of the cephalopods, offers a nearer approach to the vertebrate type than does any other articulate, in the perfect symmetry of the organs, the larger proportion of muscle, the increased bulk and concentration of the nervous centres in and near the head, in the vertical opposition of the jaws, in the gustatory papillæ of the tongue, and in the cartilaginous cephalic skeleton. The food of the nautilus consists of other mollusks and of crustaceans, showing that its natural habitat is the bottom of the sea, where it creeps about shell upward. The parts of the shell progressively vacated during the growth of the animal are successively partitioned off into airtight chambers by thin smooth plates concave toward the opening, with sinuous margins, growing from the circumference toward the centre, and pierced by the membranous siphon. The young animal, before the shell becomes camerated, cannot rise from the bottom; but the older ones can come to the surface by changes in the expansion of the soft parts, by a slight vacuum produced in the posterior part of the occupied chamber, and, according to some, by the exhalation of some light gas into the deserted chambers; they rise in the water as a balloon does in the air, with the ability also of directing the motions to a certain extent by means of the funnel; they float at the surface shell upward, and sink quickly by reversing the shell. The proportion of the air chambers to the dwelling chamber is such that the shell is nearly of the same specific gravity as the water; the siphon communicates with the pericardium, and is probably filled with fluid

from that cavity; it conducts small vessels for the nutrition of the shell, and perhaps for secretory purposes. A large and perfect shell will weigh 6 or 7 oz., and the soft parts 5 or 6 oz. more; the exterior crust of the shell is whitish with fawn-colored streaks and bands, and the interior has a beautiful pearly lustre, and is in request by cabinet makers and jewellers; by removing the external coat by acids, the pearly surface is readily exposed, and shells thus treated and richly engraved were formerly highly prized as ornaments for the mantlepiece and sideboard. This species is so common in the S. Pacific, that at certain seasons of the year they are carried by the winds and currents to the island shores, where they are used, when smoke-dried, for food; in the Papuan archipelago the shells are used as common utensils; they are found from the Persian gulf and Indian ocean to the Chinese seas and the Pacific. In the umbilicated nautilus (*N. umbilicatus*, Lester) the last whorl of the shell does not envelope and conceal the others; the shape is ventricose, the surface reticulated, and the color dusky smoky, with numerous delicate chestnut flammules (5 to the inch). In the *N. scrobiculatus* (Soland.), like the last from the S. Pacific, the surface is smooth and shining, the color ochreous, with 8 chestnut flammules to the inch, and the sides undulated with distinct waves. A nautilus extended in a straight line would be a shell like a fossil orthoceratite; in the ammonites the shell is coiled as in the nautilus, but is strengthened by arched ribs and dome-shaped elevations on the convex surface.—The paper nautilus or argonaut belongs to the octopod group of the dibranchiate cephalopods, or to the *acetabulifera* of D'Orbigny, from the arms being provided with sucking disks. The argonaut differs from the true nautilus in the arms of larger size and more complicated structure, partially connected by membrane at the base; in the larger and more complex eyes, not pedunculated but lodged in orbits; in the gills being only 2 in number, each with a branchial heart; in the funnel being an entire tube; and in the presence of an ink gland and bag for its secretion. In the genus *argonauta* (Linn.), in the females, which alone have a shell as an egg receptacle, the 1st or dorsal pair of the 8 arms are dilated into broad thin membranes, which secrete and sustain the very light, paper-like, calcareous, symmetrical, and single-chambered shell; like the other arms, these are provided with 2 rows of suctorial disks, extending around the whole circumference, by means of which the animal retains the shell in position; the 6 non-palmated arms serve as organs of prehension, of locomotion, as the animal drags itself along the bottom or climbs the rocks in search of food, and as anchors; the shell, as in the nautilus, is carried above the body. The arms are attached to the anterior part of the cephalic cartilage; the suckers are completely under the control of the animal, which can fasten or

relax them instantly. Swimming is effected in a retrograde manner by the ejected currents from the funnel. The skin is soft and tender, and includes a great number of cells containing pigment matter of different colors, whose contractions and expansions, with the surface movements, give it a remarkable power of rapidly changing its tints. There is no internal shell, and it is now ascertained that the external shell is peculiar to the female, and is only an incubating and protective nest for the eggs; it is not the homologue of the internal rudimentary shell of the cuttle fish, nor of the external chambered shell of the nautilus, but rather answers to the cocoon of leeches and other articulates, or to the egg-float of the delicate gasteropod *janthina*; the eggs are attached by thread-like stalks to the involuted spire of the shell, behind and beneath the body of the female. The best known species, the *A. argo* (Linn.), inhabits the Atlantic, Pacific, and Indian oceans, and the Mediterranean, especially about Sicily. In the last named locality Madame Power made the experiments which determined that the argonaut is the maker of its own shell, and not a parasitic occupant like the hermit crab; this question arose from the fact that the animal has no muscular or other attachment to the shell, and has been known voluntarily to quit it, and survive in captivity a considerable time without any attempt to return to it; it also repairs the shell when broken by the agency of the palmated arms. For an account of the arguments for and against parasitism (among the advocates of the former being De Lamarck, Leach, De Blainville, Broderip, and Sowerby, and among those of the latter Cuvier, Duvernoy, Ferussac, and D'Orbigny), and for an extensive bibliography on this animal, see "Proceedings of the Boston Society of Natural History," vol. v. pp. 369-'81 (1856). Leach, who considered the animal a parasite, described it as the genus *oocythoë*. The sexes are distinct; the specimens usually found are all females, the males having been until recently described as parasites under the name of *hectocotylus*; this is a worm-like body, resembling the arm of a cuttle fish, the under surface bordered with 40 or 50 pairs of alternating suckers; for a long time regarded as a parasitic annelid, it is now known to be the spermatophorous arm of the male argonaut, deciduous during sexual congress, and attaching itself within the mantle of the female; in this genus it is the 8d arm of the left side which is thus deciduous and hollowed for the spermatie receptacle. The male argonaut has no shell and no palmated arms, and is only about $\frac{1}{4}$ of the size of the female. The argonaut, according to Rang, rises to the surface shell upward, turning it downward when it floats on the water; by retracting the 6 arms within the shell and placing the palmated ones on the outside, it can quickly sink, explaining why the animal is so rarely taken with the shell. There is a specimen of this rare animal

in Boston, belonging to the family of the late Dr. J. O. Warren. The shell is flexible in the water, but very fragile when dry; a specimen, the largest known, in the cabinet of the Boston society of natural history, is 10 inches long, 6½ broad, and the opening 4 inches wide; this cost the donor \$500. Many species of the genus are described.

NAUVOO, a town of Hancock co., Ill., on a bend of the Mississippi river, near the head of the lower rapids, 52 m. above Quincy and 220 m. above St. Louis; pop. in 1857 estimated at 8,000. It was founded by the Mormons in 1840, and contained about 15,000 inhabitants at the time of their expulsion in 1846 by the neighboring people. The city was regularly laid out with broad streets crossing at right angles, and the houses were built generally of logs, with a few frame and brick buildings interspersed. A temple 180 feet long by 90 wide was erected of polished limestone. The baptistery was in the basement, and held a large stone basin supported by 12 colossal oxen. In 1848 this building was set on fire by an incendiary, and all destroyed except the walls, which on May 27, 1850, were overthrown by a tornado. For a few years subsequent to 1850, Nauvoo was the abode of M. Cabet, the French communist, and a few followers.

NAVAJOES, a branch of the great Apache tribe of Indians in the territory of New Mexico. They occupy a district between the rivers San Juan and Little Colorado, tributaries of the Colorado, but make frequent incursions into the Mexican settlements on the Rio Grande, where they commit great depredations, carrying off thousands of horses, mules, and sheep. In 1846 an expedition under Col. Doniphan was sent against them, which resulted in a treaty of very brief duration. In 1849 Col. Washington marched against them, and reached the cañon de Chellé, a fastness among the mountains exceedingly difficult to approach, where a second treaty was made. But the murder of some of their people by the Mexicans led to a renewal of hostilities on their part, which was not quieted until Col. Sumner with a strong force once more entered their stronghold in 1851, and constructed at Cañoncito Bonito, in the heart of their country, a strong military post which he called Fort Defiance. From this fort Col. Sumner marched with 6 companies of dragoons and a battery of artillery against the Navajoes; but, although several skirmishes took place between them, the Indians avoided a general fight. Finding the troops had permanently established themselves in their country, the Navajoes soon after approached the fort in a formidable body and solicited an interview. It was at once granted, and resulted in an agreement on their part to cease hostilities and depredations against the troops of the United States, the citizens of New Mexico, and the pueblas of Tunice and Moqui. Since that time these Indians have conducted themselves better toward the troops,

but their depredations continue on the Rio Grande. Major Backus, who was in command at Fort Defiance for a year, does not place so low an estimate as some others on this people. In a communication to Mr. Schoolcraft he says: "As a nation they do not deserve the character given them by the people of New Mexico. From the period of their earliest history, the Mexicans have injured and oppressed them to the extent of their power; and because these Indians have redressed their own wrongs, the Mexicans have represented them as a nation of thieves and assassins." These people were formerly represented by the hunters and trappers as considerably advanced in civilization, cultivating the soil, and dwelling in large houses; an error into which they doubtless fell by supposing them to belong to the Pueblo tribes which really possess these arts. The language of the Navajoes clearly identifies them as belonging to the Apache family, and for the advances they have made in the arts they are no doubt indebted to the Moqui, Zuni, and other Pueblo tribes near them. They cultivate to a limited extent, by artificial irrigation, the rich soil in the valleys where they have fixed residences, with rude and very primitive implements of their own manufacture. They raise corn, pumpkins, and melons, and a little wheat. They also raise horses, sheep, and a few horned cattle and goats; but the largest additions to their stock of sheep and mules are by stealing from the settlements near the Rio Grande. This, the Indian agents assert, is not done by the tribe at large, or even countenanced by it, but by bad men of the tribe whose movements the chiefs cannot control. They manufacture their own blankets and other articles for clothing, from wool taken from their own sheep, some of which are of a superior texture, and command from \$25 to \$50 in the shops of Santa Fé and El Paso. These blankets are much sought after both by Americans and Mexicans, who wear them as serapes. Cotton blankets are also found among them, but these are made by the Pueblo tribes further south, who raise their cotton. Unlike the Pueblo Indians, who live in well built houses of adobe or stone, the Navajoes dwell in rude wigwams constructed with poles and branches of trees, and often in the caverns and fissures so common in the rocky cañons (defiles) of their country. As often as they change their grazing grounds, they repair and reoccupy some deserted lodge, but never one in which a person has died. In the winter they remove to the south, where there is little snow and better pasturage for their animals. The Navajo almost lives on horseback; and few men equal him in the management of that animal. There are individuals among them who own from 400 to 500 horses, many of which are worth from \$50 to \$500 each, and some will command a higher price. Major Backus, who spent some years there, was informed by U. S. officers who attended a gathering of them, that they saw at least 2,000

horses near Cienega Juanito, feeding on the plain under the charge of herdsmen, and that in addition at least 500 Indians were mounted during the whole day and night. Col. Eaton of the U. S. army, who was also among this people, has a very low estimate of them, considering them the rudest, least intelligent, and least civilized of all the tribes of Indians he has ever seen. Such progress as they have made he thinks is owing to their intercourse with the Spanish population in New Mexico. The government of this people is patriarchal. "There are rich men among them," says Major Backus, "whose possessions consist of large herds of horses and sheep. Every drove and herd is necessarily attended by herders; hence, every man has many dependants, who are obedient to his will in peace or war. The only elective office among them is that of war chief, and such office, I believe, expires with the occasion that created it. Every rich Navajo may be considered the chief of his clan, or of his own dependants; and these clans are usually friendly with each other, and make cause against a common enemy. In addition to these, there are many who recognize no leader, and who live like vagabonds, stealing indiscriminately, as occasion offers, from friends and foes." Mr. Merriwether, the Indian agent in New Mexico, in his report for 1854 states that "there is one band of the Navajoes who have separated themselves from their tribe, and removed eastward to the neighborhood of the Utahs and Jicarillas," who have committed the depredations referred to. Like all other Indians, the Navajoes are very superstitious. They never eat the flesh of the gray squirrel, yet delight in that of the prairie dog. Their weapons of war are the lance and bow and arrows, the former very long and pointed with a sharp flint or iron. Their arrows are also pointed, and are discharged with great precision. They use a shield made of raw hide, which is almost impervious to a musket ball. On their heads they wear a sort of cap made of deer skin, crowned with feathers, which much resembles an ancient helmet. A Navajo in full costume, with his bow, arrows, lance, and shield, is a very warlike-looking character. The young women are considered the property of their parents until they marry. Prior to the marriage, a contract is made between the groom and the father of the girl. The usual consideration paid is 5 or 6 horses, but for a girl of superior beauty and accomplishments 12 and even 15 horses are obtained. A woman may leave her husband for sufficient cause. They do not maintain a high character for chastity. Mr. Gregg estimates this tribe at 10,000 souls, which Major Backus believes does not differ materially from the truth; while Governor Bent, in a communication to the government in 1846, estimates them at 7,000.

NAVARETTE, or NAVARRETE, JUAN FERNANDEZ, surnamed EL MUDO (the Mute), a Spanish artist, born in Logroño in 1526, died in Toledo,

March 28, 1579. He was of noble parentage. In his third year he lost his hearing from severe illness, and in consequence his speech also. He studied painting in the monastery of the Hieronymites at Estrella, and afterward in Florence, Rome, Naples, and Milan, spending some time at Venice as a pupil of Titian. In 1568 he was appointed painter to the king of Spain. He devoted himself mainly to sacred subjects, and the greater part of his works are in the Escurial. Navarette was well versed in sacred and profane history and mythology as well as in the science and literature of his art. He could read and write well, and expressed his ideas to others, by means of signs, with great clearness. Lope de Vega speaks of him as the Spanish artist who was best able to cope with his Italian rivals.

NAVARINO, or NEOCASTRO, a fortified town of Greece, in the Morea, at the S. extremity of the bay of Navarino, 5 m. N. from Modon, and 8 m. from Old Navarino, which stands on the N. coast of the bay, near the ruins of Messenian Pylos; pop. about 2,000. It has a citadel, situated on a high rock. The chief objects of interest are the remains of an old aqueduct, and some antique marble pillars adorning the front of the principal mosque. The bay of Navarino is about 3 m. long and 2 m. wide, with from 12 to 26 fathoms of water. It is shut in by the island of Sphacteria or Sphagia, famous for the victory achieved there by the Athenian Cleon over the Spartans, 425 B. C. The scene of Byron's "Corsair" is said to be laid in the same island, which has always been a notorious resort of pirates. Here, on Oct. 20, 1827, the combined fleets of Great Britain, France, and Russia gained a decisive victory over the Turkish-Egyptian fleet, which greatly promoted the success of the Greeks in their struggle for independence.

NAVARRÉ (Span. *Navarra*), an administrative province and captain-generalcy in the N. E. of Spain, between Aragon, Old Castile, and Biscay, bounded N. by France and the Pyrénées, E. by the provinces of Huesca and Saragossa, S. by Saragossa and Logroño, and W. by Alava and Guipuzcoa; area about 2,500 sq. m.; pop. in 1857, 808,622. The country generally is intersected by small mountain ranges projecting southward from the Pyrénées; but near the banks of the Ebro, which forms a part of the southern frontier, there are wide and fertile plains. Beside that river, Navarre is watered by its tributary, the Aragon, which, coming from the N. E., receives several smaller streams, running due S. from the mountains, and toward the N. W. by the upper Bidassoa, which falls into the bay of Biscay. While the mountainous region is bleak, cold, and unsuitable for tillage, the valleys are fertile in wheat, maize, barley, and oats. Hemp, flax, oil, wine, and liquorice are also produced; but both agriculture and manufactures in Navarre are yet in a very backward state. The facilities for trade are inconsiderable; the canal of Aragon,

which connects Tudela and Saragossa, is the principal means of intercourse with the adjoining provinces on the E., while the high road from Pampeluna to Madrid is the thoroughfare toward the S.; but Navarre will soon have its share in the railroad improvements now going on in the peninsula. It communicates directly with France through mountain passes or defiles, the most celebrated of which is that of Roncesvalles, where the army of Charlemagne was defeated, and the reputed scene of the death of Roland. In the mountains, beside the Pyrenean limestone, jasper and marble occur in large beds; there are several iron mines, and one of copper, numerous thermal springs, and a quarry of rock salt at Voltierra. The forest trees of the Pyrénées, chiefly consisting of pines, beeches, oaks, and chestnuts, furnish an abundant supply of building timber. Wolves, wild boars, foxes, and wild cats are found in the mountains. The principal occupation of the people is pasturing sheep, goats, and cattle. Wool, grain, and wine are the chief exports, and silk and cotton fabrics and colonial produce the most important imports. The Navarrese are tall and well formed, and evince an independent spirit and great attachment to their religion and ancient privileges. The Castilian language is generally used among them; but the Basque is spoken in the N. and W. districts. Capital, Pampeluna.—This province, which is sometimes termed Upper Navarre, once formed a kingdom, in conjunction with Lower Navarre, which is situated on the northern slope of the Pyrénées, within the limits of France. It was one of the first Christian principalities founded after the conquest of Spain by the Arabs, and in fact, although occasionally overrun by those invaders, was never subdued. It acknowledged for a while the supremacy of Charlemagne and his immediate successor, Louis le Débonnaire; but in 831, under Count Aznar, it vindicated its independence, which was sanctioned in 887 by the diet of Tribur. At the beginning of the 11th century, under Sancho III., surnamed the Great, its limits were considerably enlarged; and it was for a while the most powerful among the Christian kingdoms of Spain. In 1234 it fell by inheritance to Thibault, count of Champagne, whose granddaughter Jeanne in 1273 married Philip the Fair of France; and on the accession of that prince to the throne in 1285, Navarre was united to France. This union lasted 43 years; and on the accession of Philip VI. of Valois, Navarre returned to its own sovereigns. Jeanne, the daughter of Louis X. of France, the lawful heiress, brought the Navarrese crown to the house of Evreux, from which, by intermarriage, it passed in succession to the houses of Aragon in 1425, of Foix in 1479, and finally of Albret in 1484. The whole of Spanish Navarre was in 1512 seized by Ferdinand the Catholic, king of Aragon; and henceforth the kingdom was limited to the small district known as French or

Lower Navarre. By the marriage of Duke Antoine to Jeanne d'Albret Navarre was acquired by the house of Bourbon, and their son Henry of Navarre, in 1589, inherited the throne of France. His successors, until 1880, styled themselves kings of France and Navarre.

NAVARRÉTE, DOMINGO FERNÁNDEZ, a Spanish missionary, born in Penafiel, died in St. Domingo in 1689. He joined the Dominican order, and in 1647 was sent to the Philippine islands, where he became professor of theology in the college of Manila. Subsequently visiting China, he penetrated into the interior of the empire, and was for some years superior of his order in that region; but during a persecution he was apprehended and sent to Canton, whence he escaped to Macao, took ship for Europe, and reached home in 1678. In the same year he went to Rome, and protested to the pope against the policy of the Jesuit missionaries in China, whom he accused of accommodating themselves more than was lawful to the customs of the natives. In 1678 he was appointed archbishop of St. Domingo. He published *Tratados históricos, políticos, étlicos, y religiosos de la monarquía de China* (fol., Madrid, 1676). A second volume of this work, relating mainly to the disputes between the Jesuit and Dominican missionaries, was suppressed by the inquisition, and a third was written but never printed.

NAVARRÉTE, MARTINO FERNÁNDEZ, a Spanish historian, born in Abalos, Old Castile, Nov. 9, 1765, died in Madrid, Oct. 8, 1844. He was educated at Vergara, and in 1780 entered the navy as a midshipman. He cruised with the Spanish fleet in the English channel in 1781, was present at the attack on Gibraltar and the consequent destruction of the Spanish floating batteries in Sept. 1782, and afterward served against the Moors and Algerines. In 1789, being compelled to quit active service on account of his health, he was commissioned by the Spanish government to compile from the national archives a collection of documents on the history of Spanish maritime discovery. He interrupted his labors to return to sea when war was declared with France, and remained afloat until he was appointed in 1797 to a post in the ministry of marine. On the French invasion he retired to Seville, refusing to accept office under Joseph Bonaparte. In 1823 he was made chief of the hydrographical department, and for many years exercised a great influence over Spanish naval affairs, and was the virtual head of the admiralty. In the mean time he had applied himself with unabated zeal to literary labors, proposed the new system of orthography adopted by the Spanish academy in its dictionary, contributed to the transactions of the academy of history and the academy of San Fernando, of the latter of which he was secretary, and wrote a "Life of Cervantes" (Madrid, 1819). The first 2 volumes of the great work to which he devoted the best part of his life were published at Madrid in 1825,

under the title of a "Collection of the Voyages and Maritime Discoveries made by the Spaniards since the Close of the 15th Century." The 3d appeared in 1839, and the 4th and 5th in 1837. The 6th and 7th were left unfinished at the author's death. The first 2 volumes are devoted to the discoveries of Columbus, concerning whom they brought to light an immense wealth of information, consisting of letters, public documents, &c., which were the basis of Washington Irving's "Life of Columbus." The collection, though invaluable as a source of history, has no pretension to being a connected narrative, and is little read. It has received the warmest commendation of Irving, Prescott, and other historians, but its value has sometimes been called in question. Navarrete commenced in 1842, in concert with two other Spanish gentlemen, a "Collection of Unpublished Documents for the History of Spain," which was issued in numbers. Five volumes appeared during his lifetime, and it was continued after his death. He published a treatise on the Spanish discoveries on the Pacific coast of North America, prefixed to a narrative of the "Voyage of the Sutil and Mexican on the Coasts of California" (1802), and left unfinished a general history of the maritime affairs of Spain. His "Dissertation on the History of the Nautical and Mathematical Sciences in Spain" was published by the academy of history in 1846. A collection of Navarrete's smaller works was begun by his sons in 1848.

NAVARRO, a N. E. co. of Texas, bounded N. E. by the Trinity river, by branches of which it is drained; area, 1,400 sq. m.; pop. in 1857 estimated at 7,250, of whom about 2,000 were slaves. It has a rolling surface, with a rich, dark soil along the water courses, and a large portion of prairie. The chief productions in 1850 were 73,040 bushels of Indian corn and 12,197 of sweet potatoes. There were 5 grist mills and 1 saw mill. Capital, Corsicana.

NAVIGATION, the art or system of rules and practices, by means of which vessels are directed in their course upon the water. The science of navigation has grown to its present state by slow degrees, and by contributions from the most opposite sources; from practical and uneducated seamen whose ingenuity has been taxed to supply those deficiencies which experience had made known, and from the most profound and secluded philosophers, whose lives have been passed in "commerce with the skies," either by observing the motions of the heavenly bodies, or by investigating the laws by which those motions are regulated. The most valuable services to navigation, however, have in several cases been performed by those who have combined an experience of the sea with astronomical science, and who therefore were both acquainted with the seaman's needs, and qualified to meet them.—The history of navigation embraces in an important degree what Prof. Guyot calls the

"geographical history of man." As the indispensable auxiliary of commerce, it has taken a large part in human progress, and especially in those discoveries, whether earlier and less connected, or later and more important, which have the nature of sudden leaps or bounds in human affairs. The free and open paths of the sea have proved to be the paths of knowledge and civilization, narrow in the beginning, but afterward widening sufficiently to take in the whole earth. If, indeed, we glance back into the remote ages, we perceive that the most forcible and pregnant illustrations of the condition of man at certain epochs may be derived from the state of navigation at those epochs. Thus, for example, the obscure period of the enterprise of Jason, before any vessels had ventured beyond the *Ægean* archipelago to the west, even so far as the Italian peninsula, is strikingly contrasted with the period of commerce and colonization of the Phœnicians, or with that of later Greece. A vast change took place in the affairs of men when the art of navigation, no longer limited to the shores of the Mediterranean and the coasts of Europe, led the way across the great oceans, and circumscribed the globe. In the history of navigation, as elsewhere, we are obliged to commence with periods and events that are partially fabulous, though founded upon actual occurrences. The expedition of the Argonauts, concerning which the language of the early Greek writers is so mythical, is now regarded as a final and triumphant effort to open the Euxine sea to the national enterprise. "The legend of Prometheus and the unbinding the chains of the fire-kindling Titan on the Caucasus by Hercules in journeying eastward, the ascent of Io from the valley of the Hybrides toward the Caucasus, and the myth of Phryxus and Helle, all point to the same path on which Phœnician navigators had early ventured." (Humboldt.) As the expedition of the Argonauts to Colchis opened the way to the east, so the voyage of Colæus of Samos, who sailed for Egypt, but was driven by easterly storms, "not without divine direction," says Herodotus, beyond the pillars of Hercules into the ocean, extended the commerce and intercourse of the Greeks to the peninsula of Spain (Iberia), and discovered a region which, like the eastern basin of the Black sea, had before been only a ground for mythical conjectures, the way that led to the Elysian fields and the Hesperides. Interposed between this age and the historical period of Grecian navigation and colonization, appear the Egyptians, the Phœnicians with their African colonies, particularly Carthage, and the Etruscans. There is satisfactory proof that the Egyptians navigated not the Nile alone, but the Arabian gulf also; and the canal from Suez, begun before the exodus of the Hebrews (and, after so long a period of neglect and decay, about to be reconstructed, probably, in our own time), had for its object a free access to the Arabian copper

district. The Phœnicians were associated with Egyptians in voyages of greater length; the most remarkable of these is the alleged circumnavigation of Africa. The truth of the account of this event, as given by Herodotus, is confirmed by an observation which seemed to the historian the most incredible, "that those who sailed around Lybia, in sailing from east to west, had the sun on their right hand." Concerning those commercial enterprises of the Phœnicians which were directed toward the east, as well as concerning their wealth, we have the testimony of the prophet Ezekiel, who, in prophesying the dreadful fall and the judgment of Tyre, describes her riches, magnificence, and wide-spread commerce; and a further testimony in the history of Solomon's employing King Hiram and his navy, in bringing from Ophir "gold, great plenty of almag trees, and precious stones." It is chiefly, however, through her colonies that the bold and well directed character of Phœnician navigation manifested itself, and exercised the greatest influence upon human progress. It is impossible now to separate the fabulous from the true in the story of Cadmus; but it is nevertheless probable that "it was through the commercial intercourse of the Ionians with the Phœnicians that the Greeks received the characters of their alphabetical writing, which were long termed Phœnician signs." Phœnician navigation led to the general diffusion of trade throughout the Mediterranean sea, and Phœnician colonies on the south of Spain and in the north of Africa preserved and continued the same spirit of enterprise long after the decline of the parent state, when the course of empire had commenced its march to the westward, and Rome had become the rival of Carthage. But the interest attached to these colonies goes still further. It serves to connect, by a delicate link, the most conspicuous enterprises of navigation in the ancient world with the boldest and most successful voyages of modern times. It was from the vicinity of a Phœnician settlement that Columbus took his departure for the discovery of America. And in this chain of connection there is still another link, which is the discovery by the Phœnicians of the islands of Porto Santo, Madeira, and the Canaries, which moved the "geographical myth of the Elysium further and further beyond the pillars of Hercules, and must be regarded as the first step in that direction (the navigation of the great oceans) in which the efforts of the mariner were long directed before being crowned with success." As the Greeks succeeded the Phœnicians and Egyptians, so they, in turn, were succeeded by the Romans, who had imbibed from the Etruscans a taste for trade. Our object being merely to trace out the gradual expansion of navigation, we shall not give any space to the military enterprises of the Greeks and Romans conducted by sea. The art of navigation was not improved, nor its field extended, dur-

ing the dark ages. The barbarous nations who dismembered the Roman empire, and the Saracens, confined all their expeditions to the Mediterranean sea. The Normans and Danes, in their northern coasting excursions, made chiefly for plunder, added little to the stock of knowledge. Subsequently, the Genoese and Venetians, by their practice upon the sea, whether for trade or war, seemed to be preparing a school for the training of future discoverers, without doing any thing more themselves than changing the forms of vessels, or improving the means of propulsion by a more convenient distribution of the sails and rigging.—Hitherto we have seen that the most prominent feature of navigation is, that it has been limited to enclosed seas like the Mediterranean, to gulfs and archipelagos, and to the coasts. Beyond the sight of land, the mariner had no guide in cloudy nights, and no resource in stormy weather; consequently, the most remote and venturesome expeditions only crept along the shore; and the sea was avoided as much as possible during the winter season, from the middle of November to the middle of March. The discovery of the mariner's compass changed this state of things entirely, by furnishing a never-failing guide, as useful and safe to the navigator in the night as during the day, and in storms as in fair weather. It is uncertain to whom the world is indebted for the first observation of the directing powers of the magnet, and for the equally great boon of their application to the purposes of travelling by land and sea. "In a Chinese work belonging to the first half of the 2d century, mention is made of magnetic cars given, more than 800 years before, to the ambassadors from Tonquin and Cochin China, that they might not miss their way in their homeward journey by land. A century later, Chinese ships used the south magnetic direction, to guide their course in the open sea." (Humboldt.) The introduction to Churchill's "Collection" contends (passionately, we may say) for the honor of the discovery in behalf of Flavio Gioja of Pasitano, near Amalfi, in Campania; whence *Prima dedit navis usum magneti Amalfis*. The date assigned to Gioja's invention is about the beginning of the 14th century. But the use of the compass is mentioned in a politico-satirical poem written in 1190, and by Jacob of Vitri, bishop of Ptolemais, 1204-'15. Dante alludes to it in his *Paradiso*:
Si moese voce che l'ago alla stella.

There can be no doubt that to Flavio Gioja belongs the merit of having invented something by which its adaptation to nautical purposes was very much promoted; but that it was used at sea before his time appears from the nautical treatise of Raymond Lully of Majorca, who says in his *Fenix de las maraxillas del orbe*, written in 1286: "The navigators had an instrument" (probably an astrolabe for observing the sun), "sea chart, and mariner's compass." We may here observe, by the way, that Majorca, always famous for its sailors,

seems to have possessed also men distinguished in nautical science; for a little more than a century later, Henry, duke of Visco, brother of Edward, king of Portugal, sent for one Master James, from the island of Majorca, to teach navigation and make instruments and charts for the sea. But though we are left in doubt as to when the compass was brought into familiar use among the Europeans, we have no difficulty in deciding upon its indispensable importance. Without it, Vasco da Gama and Columbus, and their companions and successors, could not have executed their grand projects of discovery. The discovery of the compass divides the history of the art of navigation into distinct periods: the ancient, when the chief nautical enterprises of trade and war were confined to the Mediterranean, round which interior sea the most civilized and progressive nations were settled (to use the language of Socrates), "like ants or frogs round a marsh" (*Phædo*, Cary); and the modern, when the navigation of the oceans commenced, and the timid adherence to the land was abandoned. Having briefly reviewed the former, it remains for us to give a short account of the rise of the modern art of navigation, and to explain in a popular manner some of its principal processes.—When ships, carrying with them an unfailing guide to direct their course, began to traverse the great seas in all directions, the cross staff and the astrolabe furnished them with the means of measuring the altitude of the sun and stars, and thus of approximately determining the latitude and time. But the most serious inconvenience arose from the unavoidable use of a plane chart, to represent or misrepresent the sphere, the gross distortions and errors of which often misled the mariner, especially in voyages far distant from the equator. Recourse was had to globes to remove this evil, and a famous pair is mentioned which were made in 1592, under the direction of Mr. William Sanderson, a merchant, "commended for his knowledge as well as generosity to ingenious men." On the terrestrial one were described the voyages of Drake, Cavendish, and Frobisher. Mr. Robert Hues, who had been at sea and was a man of letters, wrote, among other meritorious pieces, an elaborate tract in Latin on the use of these globes. The plane chart, however, being so much more easy and convenient in practice, kept its place until the invention of Gerard Mercator, a native of Rupelmonde, in East Flanders, in 1569, supplied the long sought for remedy. Mercator's projection of the sphere upon a plane surface consists in keeping the meridians parallel, but augmenting the length of the meridians between the parallels of latitude, in receding from the equator, in such a manner that the just proportions of the meridians and parallels of latitude to each other are preserved. The great advantage of this projection is, that the directions of the compass, or what in technical language are called the "compass courses,"

are straight lines. The navigator works most conveniently upon a plane surface, and by means of Mercator's projection he is enabled to lay down his courses with a parallel rule, the points being taken from a compass drawn on the chart, and the line being one that cuts all the meridians at the same angle, and marks the magnetic bearing of the objects through which it passes. This is called the rhumb line or loxodromic curve, and the definition of it answers for the definition of the compass course. Such is the suitableness of Mercator's projection to the use of the mariner's compass, that the latter now seems to have been an incomplete discovery until the announcement of the former. It is suggested that Mercator arrived at his invention by simply observing on the globe where the meridians were cut at each parallel of latitude by the rhumb lines; and it is admitted that he never laid down, if he knew it, the mathematical theory on which it rests. This was first announced by Edward Wright, of Oriel college, Cambridge. Shortly after this (1595), the famous navigator, Capt. John Davis, who gave his name to the straits which he discovered, published a small treatise called "The Seaman's Secrets," at the end of which he gives a figure of a staff of his contrivance, to make a back observation; "than which instrument," he said, "the seaman shall not find any so good, and in all climates of so great certaintie." The celebrated Portuguese mathematician, Pedro Nunez, or Nonius, had as early as 1587 published his book, which, with additions, was printed 80 years after by Basil in Latin, and called *De Arte et Ratione Navigandi*. In this he introduces, among much of what was then very valuable matter, his method of the division of a quadrant by concentric circles. Davis's back staff maintained the first place until it was superseded by the quadrant. Another important invention is the log, first mentioned by Pigafetta in the beginning of the 16th century. About the year 1620 logarithms were introduced into navigation by Edmund Gunter, whose scales are of such general repute; and shortly after, Richard Norwood published his method of setting down and perfecting a sea reckoning, with the use of a traverse table. In 1700 Dr. Halley published a general map, on which were delineated the lines of equal variation. It was hailed with great applause, as the means of determining the longitude at sea; how futile this expectation proved is now well known. But of all the gifts to the navigator, by far the greatest of this time is Hadley's quadrant. It has been superseded by the sextant, which does not differ from it in principle, but is very much more nicely constructed, and more accurate, convenient, and generally useful. (See QUADRANT, and SEXTANT.) For a long time the problem of the longitude engaged the attention of the men of science in Europe, and especially in Great Britain. The British house of commons has at various times offered rewards for the solution of this problem,

one of which amounted to £20,000 sterling. Newton's improvement of the theory of the moon led to the construction of Mayer's lunar tables, and to the publication of the "Nautical Almanac and Astronomical Ephemeris," by Dr. Maskelyne, in 1767. The appearance of the latter created a new era in navigation, to which it rendered essential service. The lunar method, as it is called, has since received great additions, corresponding to the advancing state of astronomical knowledge, and the improvement in the instruments of the seaman and the astronomer. The method by the chronometer owes its highest success to the science and ingenuity of English artists and mechanics of the present generation, and that immediately preceding. (See CHRONOMETER, and LONGITUDE.) In our day the art or science of navigation has not failed to receive valuable accessions; such as Sumner's method for determining the position by lines of bearing or of equal altitudes; Chauvenet's (professor U. S. N.) great circle protractor, which furnishes great circle courses immediately by inspection, saving a world of figures, and also solves, in the same way, the problems of nautical astronomy; precise and trustworthy sailing directions and memoirs, like those of Horsburgh, the Blunts of New York, Findlay, and the invaluable memoirs of Kerkhallet; and valuable contributions to our knowledge of the laws of storms by Redfield, Reed, and Piddington, and of the currents and meteorology of the ocean generally, by Berg-haus, Johnston, and Maury.—Thus far we have aimed to give a succinct account of ancient navigation, and a brief sketch of the progress of the art in modern times, just before and after Columbus had received in a dream, near the river Belem, "the keys which opened the gates to the great ocean." A scientific treatise on navigation does not come within the scope of our work; for this we refer the student to the professed teachers and books, and above all to Bowditch's "Navigator," a work which displays a singular power in the practical application of science to the uses and wants of every-day life. But without attempting a scientific treatise, we may give the general reader, in a very few words, a simple conception of the manner in which the place of a ship and her direction are ascertained upon the sea, under favorable circumstances. When the ship has left port, the reckoning is begun by observing the compass bearing and distance of some conspicuous object, as a lighthouse; and from the time of taking this bearing, the reckoning is continued by noting down (generally from hour to hour) the courses sailed, and the distance on each course. The reckoning is made up with these data, from the time of any independent determination of the ship's position, by considering the sum of the distances sailed in the N. and S. and E. and W. directions, and reducing the whole to one residual expression of the actual course and distance made good; this is done by means of a traverse table in-

vented for the purpose. The reckoning here described is called dead reckoning, and is susceptible of error from so many disturbing causes, that it can only be depended upon for a short time. The navigator is provided with simple and easy methods of acquiring a knowledge of his position by independent observations of the sun, moon, and stars. We will look only at the first of these luminaries. The elements of position are the latitude and longitude. The determination of the latitude by the altitude of the sun at noon is readily understood, if it be remembered that if the sun moved always on the equator, the height it reached at noon at any place would depend merely on the distance of that place from the equator; but the sun being removed from the equator more or less, according to the season of the year, the navigator reduces it to that circle by applying the declination which is the astronomical expression in degrees and minutes for the interval of its separation. For this declination and all his astronomical data, he is indebted to the nautical almanac. The longitude is determined by chronometers. A chronometer is expected to keep the time of a certain place, as Greenwich or Paris; but as all chronometers are subject to a slight rate of loss or gain, this rate, and the error at starting, are applied at the moment of observation, to obtain the correct Greenwich time. The change of a degree in longitude is equivalent to a change of 4 minutes in time; the business of a navigator then is simply to compare his own time with the standard time, or the time at Greenwich; he obtains his own time through an observation of the sun when its altitude is changing rapidly. In the case of the determination of the longitude by the lunar method, the clock showing the Greenwich time is in the sky. Such observations are detached and disconnected. The navigator, if set down suddenly in the middle of the ocean, could determine his position as well as if he had proceeded there gradually, and known it from day to day.—We have selected single and plain cases only; but navigation, regarded as an art, is a copious and complex system of rules and practices, involving the use of numerous tables. Bowditch's "American Navigator" is a large octavo of nearly 800 pages, containing over 50 tables. Raper's "British Standard Navigator" (edition of 1849), approved by the admiralty, numbers 900 pages and 74 tables. Navigation, regarded as a science, requires, at the very least, a knowledge of spherical trigonometry and algebra in the mathematics, and of the apparent motions and phenomena of the principal heavenly bodies in astronomy. In addition to the above named authorities, see Peirce's "Plane and Spherical Trigonometry;" Chauvenet's "Trigonometry" and "Manual of Astronomy;" Francœur's *Astronomie pratique*; Boitard and Ansart-Deusey, *Navigation pratique*; Churchill's "Collection," introductory discourse; Dr. Wilson's

"Dissertation," in Robertson's "Elements;" and Humboldt's "Cosmos."

NAVIGATION LAWS, the name usually given to those enactments by which commercial states have endeavored to regulate the navigation which left or visited their ports, seeking always to favor and promote the commerce of the state enacting them. Such laws have existed in some form among all the maritime states of Europe for many centuries. The earliest systematic effort of this kind was probably that of Spain, 250 years ago, to preserve the exclusive possession of her very profitable commerce with her American colonies. In England, so far back as 1879, in the reign of Richard II., a statute was passed prohibiting the king's subjects from importing or exporting merchandise except in English ships. After this time sundry enactments were passed for a similar purpose. But the navigation laws of England, so called, properly began in Cromwell's time. Then the long pending conflict for the supremacy of the seas, between Holland and England, came to a crisis. The contest continued after the restoration of Charles II. But the fatal blow was given to Holland, and the superiority of England made certain, not so much by her naval victories as by the navigation laws, which, originating in the sagacity of Cromwell, and receiving then the form they have preserved until recent times, secured to England, first, the building of all her ships and their navigation by English seamen; next, the absolute monopoly of her colonial commerce; and finally, her full share of the general carrying trade of the world. For these purposes it was provided that no ship should be deemed a British ship that was not wholly built within the dominions of Great Britain, and wholly owned by British subjects, and navigated by a British commander and a crew of which at least three fourths were British subjects; next, that only British ships should carry any merchandise from any port of the British empire to any other; and thirdly, that no goods which were the growth, product, or manufacture of Asia, Africa, or America, should be imported into any of the ports of Great Britain, except in British ships, or in ships of the countries of which the goods were the production. The rigorous execution of these laws, and the consistent adherence to these principles are supposed by many to have done more than any other one cause in giving to Great Britain her enormous commerce. In order to ascertain what were British ships, and secure the execution of these laws, an admirable system of registry was adopted and remained in force in England during almost two centuries, with no substantial change. But in 1850 the principle of free trade was permitted to break down this monopoly to some extent. In the 12th and 13th Victoria it was enacted, first, that ships which are not of British build may become British ships by registry, if wholly owned by British subjects; and next, that any ship may bring to

England any merchandise, excepting, however, that the king or queen of England, by order in council, may interpose such changes, restrictions, or prohibitions upon ships of any country as will put the ships of that country when in British ports on the same footing on which British ships stand in the ports of that country. —This subject was one of the earliest to which the American congress, under the present constitution, turned its attention; and in the winter of 1792-'8 acts were passed which were substantially the same as the English acts, but, so far as they differ, may be considered as more rigorous. These statutes are still in force, having never been materially altered. The maritime nations of continental Europe have their own systems of navigation laws, but these are not in any case quite so stringent as those of England and the United States. During the years which immediately followed the adoption of our constitution, England and France being constantly at war, we had almost the whole carrying trade of the world; and its vast profits laid the foundation of the wealth of this country, and built up its commercial marine with a rapidity unexampled in the history of the world. With all the conflicts of parties and of theories which are inevitable in a free country, we are not aware that any party, or indeed any individuals of influence, have objected to the principles of our navigation laws, or have proposed any changes in them, excepting such as were intended to simplify their operation and make them more effectual.

NAVIGATORS' or SAMOAN ISLANDS, a group in the S. Pacific, between lat. 13° 30' and 14° 30' S. and long. 168° and 173° W. There are 4 principal islands, viz.: Manua, Tutuila, Upolu, and Savaii; and 5 smaller: Rose island, Oloosinga, Ofoo, Manono, and Apolima, beside some islets; area of the whole estimated at 2,650 sq. m.; pop. about 56,000. Rose or Kordinkoff island, the easternmost, is low, small, uninhabited, and the resort of innumerable birds. Manua, or Omanooau, called Opoun by La Pérouse, rises in the form of a regular dome to the height of 2,500 feet; it is 16 m. in circumference, covered with luxuriant vegetation, and inhabited. Oloosinga is a narrow ledge of rocks, 3 m. in length, and 24 sq. m. in area, with a strip of land about 500 yards wide, on which grow breadfruit and cocoanut trees sufficient for all the wants of the natives. It has been made the residence of the chief of Manua since that island became desolated by the wars of the Christian converts with the unbelieving natives. The coral reef around this island is very curious, and consists of two regular shelves, the outer one from 50 to 60 feet wide, and the inner in some places measuring 140. From a distinct mark of high water, which was 20 feet above the ordinary sea tide, it appears to have been upheaved to that height. Ofoo, which lies to the W. of the island just described, is the Fanfoué of La Pérouse, and has an area of about 10 sq. m., with but

few inhabitants. Tutuila is high, broken, of volcanic appearance, 17 m. long and 5 m. wide; area, 240 sq. m.; pop. 8,000. It is hilly, covered with luxuriant vegetation, and thickly settled round the shores, more particularly at the S. W. end, where the village of Leone is situated. This end is lower and more easily cultivated than the E., which is high and rugged; and the only communication between the two is by the sea shore, the hills being too difficult of ascent to pass over. There are many desirable ports or bays on the N. side, where ships may obtain supplies. The best port is Pago-Pago on the S. side, sometimes called Outhbert's harbor, after the commander of the first ship that entered it. Its entrance is narrow and somewhat concealed, but easy of access; it is surrounded on all sides by inaccessible mural precipices from 800 to 1,000 feet high, with the lower parts of the rocks bare, but the upper densely clothed with vegetation. The village of Pago-Pago contains about 80 dwellings, a council house, and a church. Tutuila is the Maouna of Bougainville, and has acquired an ill reputation from the massacre of the comte de Langle, M. de Lamanon, the naturalist, and the rest of a boat's crew belonging to La Pérouse's expedition. This was provoked by one of the natives having been shot on board the *Astrolabe*. Subsequent experience has proved that the bad character given to these people in consequence does not really belong to them. Upolu, Ojalava, Oahtooa, Ojatava, or Opoloo, is 36 m. from Tutuila and about 40 m. long; area, 560 sq. m.; pop. 25,000. The E. portion is much more rugged than the W., and the island is of moderate height, rising gradually in a succession of ridges from a low shore, lined with a coral reef, passes through which lead to snug and convenient harbors. It has been the theatre of a great deal of missionary exertion. Apia, on the N. side, is the chief town of the island. It is pleasantly situated, has a neat church, and several good buildings. The harbor can accommodate about 6 moderately sized vessels; and pigs, poultry, excellent yams, fruit, and fire wood are abundant. It is the seat of a U. S. consul. Manono island, another missionary station, is enclosed within the sea reef of Upolu, at its W. end, and was called by La Pérouse Platte island; area, 9 sq. m.; pop. about 1,100. Apolima, about a mile distant from Manono, forms a sort of natural fortress; area, 7 sq. m.; pop. 500. It is evidently the crater of an extinct volcano, and is a ring of perpendicular cliffs, with an opening at a single point on the N. side, which affords an entrance for but one boat at a time to the basin within. Savaii, the westernmost and largest island of the group, is about 7 m. distant from Apolima. It was called Chatham island by Capt. Edwards, Shavié and Oteewhy by La Pérouse, and Pola by Kotzebue and others. It is about 40 m. in length and 20 m. in breadth; area, 700 sq. m.; pop. 20,000. The shore is low, and the ascent

thence to the centre is gradual, except where the cones of a few extinct craters are seen. In the middle of the island a peak rises above 4,000 feet. Capt. Wilkes saw it at the distance of between 50 and 60 m. The interior of the island is rarely entered even by natives, and has never been penetrated by strangers. The island is said to produce the citron, nutmeg, indigo, coffee, and sugar cane. The bay of Mataatua, at the N., affords good anchorage. The town of Mataatua, beautifully situated in an extensive grove of cocoanut trees, contains about 400 houses and 2,000 people.—All of the Navigators' islands, with the exception of Rose, are of volcanic origin, and have remains of extinct craters, which are peculiarly noticeable at Apolima, Savaii, and on the ridge of Upolu, which is 2,570 feet above the sea. Their soil is rich, and is formed chiefly by the decomposition of volcanic rocks. The climate is moist, and vegetation is luxuriant. During the winter months there are long and heavy rains, attended at times with high wind and gales from the N. Destructive hurricanes also occur. The woods in the interior of the islands are very thick; among them are tree ferns, a species of banian, pandanus, and several species of palms. A species of *cerbera*, bearing beautiful clusters of large and odorous white flowers, yields a quantity of white viscid sap. The breadfruit is the most abundant of all the trees, and grows to a large size; the vi apple, the cocoanut, the wild orange, lemon, banana, taro, paper mulberry, tacca (from which arrowroot is made), coffee, sweet potatoes, pineapples, yams, papaya, two species of wild nutmeg, rattans 90 feet in length, bamboos, wild ginger, and wild sugar cane are abundant; the last is used for thatching houses. Tobacco is grown in small quantities. Efforts are making to introduce the best mode of cultivating sugar cane, and manufacturing sugar. Great attention is paid to the cultivation of the yam. There are no traces among these islands of any native mammalia, except a species of bat (*pteropus ruficollis*); but swine, horned cattle, and horses have been introduced. Poultry of all descriptions is plentiful, and pigeons abound, but are considered sacred and not used as an article of food. There are few game birds, none of the hawk genus, but many singing birds.—Among the Polynesian islands the inhabitants of the Navigators' group rank, in point of personal appearance, second only to the Tongese. The women are not so well formed as the men, and rather inclined to be stout. The average height of the men is 5 feet 10 inches. Some of them have the eyes placed obliquely like the Chinese. They have but little beard, and their hair is strong, straight, and black. Those who have embraced Christianity shave their heads. Both sexes show great kindness and love for their children. They display the greatest ingenuity in the construction of their houses, which are built of the wood of the breadfruit tree, and thatched with wild

sugar cane or pandanus leaves. There is no floor, but the ground is covered with small stones. On the pavement are laid coarse mats, with finer ones spread above, covering about half the area; when not immediately required these latter are rolled up. Mats are suspended about as screens; and at night each person is usually supplied with a mosquito curtain. Many whitewashed houses are now to be seen, for the natives have been taught the use of lime by the missionaries. There are some foreign carpenters on the islands. The food of the natives generally consists of bread-fruit, bananas, taro, sweet potatoes, and yams; an abundant supply of fish is procured from the reefs; and they also eat the chestnut, vi apple, and arrow root, the fecula of which they now manufacture in some quantities. A large wood maggot, which is found on the trees, is looked upon as the most delicious food. The men do all the hard work, even the cookery. The women are held in much consideration; they take care of the house and children, prepare the food for cooking, do all the indoor work, and manufacture the mats and tapa. The people are cleanly in their habits, of a social disposition, and fond of travelling, often undertaking journeys around their islands that occupy 2 or 3 months, during which time they live on the hospitality of those whom they visit. A harbor duty of \$5 is paid by all merchant ships to the chief of Apia. Some cocoanut oil is made. Since the French have taken possession of the Society islands, Apia has succeeded Papeete in Tahiti as a centre of English and American interests. The French have diverted to Tahiti a part of the commerce now rising in the Navigators' islands, but the chief part of the traffic is with Sydney.—The first attempt to introduce Christianity was made by the captain and crew of a vessel which was wrecked on the island of Upolu. They met with some success and built several churches. English missionaries arrived a few years later. They were from the first taken under the protection of the most powerful chiefs, and have established schools in many of the villages. A printing press has been set up at Upolu, a great portion of the Scriptures has been translated and published, and more than half the people have embraced Christianity. In addition to the Protestant missionaries, there are several Roman Catholic establishments. The ancient religion of the islanders acknowledged one great God, but they paid less worship to him than to some of their war gods. They had a god of earthquakes, a god who supported the earth, and gods of lightning, rain, and hurricanes, and also many inferior gods who watched over certain districts; and they had carved blocks of wood and stone, erected in memory of certain chiefs, whom they worshipped. The rule of the hereditary chiefs is acknowledged, and the distinction of the several classes well defined. There is no distinct name for the common

people as a class, but the chiefs in speaking of them always apply some opprobrious epithet. The son of a low-born woman by a chief ranks as a chief, although he has no authority; and the son of a noble woman by a man of mean birth may be either a chief or a commoner. The lands are allotted and distinguished by known boundaries. The natural heir of the former owner succeeds to his lands, and is the feudal chief or leader in war, but his dependants are free to cultivate a portion of his land. Each district and town has its own government. An elderly chief generally presides, or is considered the head of the village, town, or district. The supreme power lies in the high chiefs of the Molo, or "conquering party." They assemble and determine the general laws, and may levy contributions, particularly on those they have conquered.

NAVY, a collective term for the vessels of war belonging to a sovereign or nation. The war fleets of the ancients, though often numerous, were insignificant when compared with those of the present day, in regard to the size of the ships, their powers of locomotion, and their aptitude for offence. The sea-going vessels of Phœnicia and Carthage, of Greece and Rome, were flat-bottomed barges, unable to live in a gale of wind; sea room, in a squall, was destruction to them; they crept along the coasts, casting anchor at night in some cove or creek. To cross over from Greece to Italy, or from Africa to Sicily, was a dangerous operation. The ships, unfit to carry the press of sail to which our modern men-of-war are accustomed, were provided with but little canvas; the oars were relied upon to propel them sluggishly through the waves. The compass had not yet been discovered; latitudes and longitudes were unknown; and landmarks and the pole star were the only guides in navigation. The implements for offensive warfare were equally inefficient. Bows and arrows, javelins, clumsy ballistas and catapults, were the only arms that could be used at a distance. No serious harm could be done to an enemy at sea until the two fighting ships came into actual contact. Thus, there were but two modes of naval fighting possible: to manœuvre so that the sharp, strong, iron-pointed prow of your own ship should be driven with full force against the enemy's broadside in order to run him down; or else to run on broadside to broadside, fasten the two ships together, and board the enemy at once. After the first Punic war, which destroyed the naval superiority of the Carthaginians, there is not a single naval engagement in ancient history offering the slightest professional interest, and Roman dominion soon put an end to the possibility of further naval contests in the Mediterranean.—The real birthplace of our modern navies is the German ocean. About the time when the great mass of the Teutonic tribes of central Europe rose to trample down the decaying Roman empire and to regenerate western Europe, their brethren

on the northern shores, the Frisians, Saxons, Angles, Danes, and Northmen, began to take to the sea. Their vessels were firm, stout sea boats, with a prominent keel and sharp lines, relying mostly on sails alone, and not afraid to face a gale in the middle of that rough northern sea. It was with this class of vessels that the Anglo-Saxons passed from the mouths of the Elbe and Eider to the shores of Britain, and that the Northmen undertook their roving expeditions, extending to Constantinople on the one side and America on the other. With the construction of ships that dared cross the Atlantic, navigation underwent a complete revolution; and before the middle ages had passed away, the new sharp-bottomed sea boats had been adopted on all the coasts of Europe. The vessels in which the Northmen made their excursions were probably of no very large size, perhaps not exceeding 100 tons burden in any case, and carrying one or at the outside two masts, fore-and-aft rigged. For a long time both ship building and navigation appear to have remained stationary; during the whole of the middle ages vessels were small, and the bold spirit of the Northmen and the Frisians had passed away; whatever improvements were made were owing to Italians and Portuguese, who now became the boldest sailors. The Portuguese discovered the route by sea to India; two Italians in foreign service, Columbus and Cabot, were the first since the times of Leif the Northman to cross the Atlantic. Long sea voyages now became a necessity, and they required large ships; at the same time the necessity of arming vessels of war and even merchantmen with heavy artillery, equally tended to increase size and tonnage. The same causes which had produced standing armies on land, now produced standing navies afloat; and it is from this time only that we can properly speak of navies. The era of colonial enterprise which now opened for all seafaring nations, also witnessed the formation of large fleets of war to protect the newly formed colonies and their trade; and a period followed richer in naval struggles and more fruitful to the development of naval armaments than any that preceded it.—The foundation of the British navy was laid by Henry VII., who built the first ship called "The Great Harry." His successor formed a regular standing fleet, the property of the state, the largest ship of which was called the *Henry Grace de Dieu*. This vessel, the largest ever built up to that time, carried 80 guns, partly on two regular flush gun decks, partly on additional platforms both forward and astern. She was provided with 4 masts; her tonnage is variously stated at from 1,000 to 1,500. The whole of the British fleet, at the death of Henry VIII., consisted of about 50 sail, with an aggregate tonnage of 12,000, and manned by 8,000 sailors and marines. The large ships of the period were clumsy contrivances, deep-waisted, that is to say, provided with towering forecastles and poops, which rendered them exceedingly top-heavy.

The next large ship we hear of is the *Sovereign of the Seas*, afterward called the *Royal Sovereign*, built in 1687. She is the first vessel of whose armament we get something like an accurate account. She had 3 flush decks, a fore-castle, a half deck, a quarter deck, and a round house; on her lower deck she carried 30 guns, 42 and 32-pounders; 80 on her middle deck, 18 and 9-pounders; on her upper deck 26 lighter guns, probably 6 and 8-pounders. Beside these, she carried 20 chase guns and 26 guns on her fore-castle and half deck. But on her regular home establishment this armament was reduced to 100 guns, the full complement being evidently too much for her. As to the smaller vessels, our information is very scanty. In 1651 the navy was classed in 6 rates; but beside them there continued to exist numerous classes of unrated ships, such as shallops, hulks, and later bombs, sloops, fire ships, and yachts. In 1677 we find a list of the whole English navy; according to which, the largest first rate three-decker carried 26 42-pdrs., 28 24-pdrs., 28 9-pdrs., 14 6-pdrs., and 4 8-pdrs.; and the smallest two-decker* (fifth rate) carried 18 18-pdrs., 8 6-pdrs., and 4 4-pdrs., or 30 guns in all. The whole fleet consisted of 129 vessels. In 1714, we find 198 vessels; in 1727, 178; and in 1744, 128. Afterward, as the number of vessels increases, their size also gets larger, and the heaviness of the armament is augmented with the tonnage. The first English ship answering to our modern frigate was built by Sir Robert Dudley, as early as the end of the 16th century; but it was not till fully 80 years later that this class of ships, first used by the southern European nations, was generally adopted in the British navy. The particular fast-sailing qualities of frigates were little understood, for some time, in England. British ships were generally over-gunned, so that their lower ports were but 8 feet from the water's edge, and could not be opened in a rough sea, and the sailing capacities of the vessels were also greatly impaired. Both the Spaniards and the French allowed more tonnage in proportion to the number of guns; the consequence was that their ships could carry heavier caliber and more stores, had more buoyancy, and were better sailers. The English frigates of the first half of the 18th century carried as many as 44 guns, of 9, 12, and a few of 18 lbs. caliber, with a tonnage of about 710. By 1780 frigates of 38 guns (mostly 18-pdrs.) and of 946 tons were built; the improvement here is obvious. The French frigates of the same epoch, with a similar armament, averaged 100 tons more. About the same time (the middle of the 18th century) the smaller men-of-war were more accurately classed in the modern way as corvettes, brigs, brigantines, and schooners. In 1779 a piece of ordnance was invented (probably by the British Gen. Melville) which changed to a great extent the armaments of most navies. It was a very short gun, with a large caliber, approaching in its shape a howitzer, but intended to throw solid

wise obtained if the government is satisfied as to the good character and ability of the person to support himself. When admitted in any of these free cities, the citizen's or burgher's oath is taken, equivalent to an oath of allegiance.—In Switzerland every man, even a native, is regarded as a vagrant or a man without a home, and chased from canton to canton, unless he is a citizen of some commune. This citizenship is obtained upon the payment of the requisite fee into the treasury of the commune. In the case of foreigners, naturalization is granted by the legislature in some cantons, in others by the executive. No period of residence or qualification is necessary, but the cantons are jealous of foreigners and disposed to be exclusive. In the aristocratic cantons it is almost impossible for any but a wealthy man to obtain naturalization. In Ticino full citizenship is not obtained until 5 years after naturalization; but in Bern, Vaud, Zürich, Geneva, and most of the cantons, it is conferred when the alien is naturalized. A citizen of any community of one of the cantons is on an equal footing with those of any other canton. He may reside, do business, and enjoy every civil and personal right, but not political rights.—In Portugal an application must be made to the king through the secretary of foreign affairs, which is referred to the council of state. The applicant must be over 25 years of age, have resided in the country two years, and have the means of subsistence. The residence for two years is dispensed with upon proof that he has married a Portuguese, or been useful to the state by embarking in commerce, improving any branch of the arts, or introducing any new trade, manufacture, or invention, or by opening or improving a public road; and they are generally dispensed with in the case of mariners, as it has been the constant policy of Portugal to encourage foreigners to enter and augment its marine.—In Spain, by the ancient law of the realm, no foreigner could be naturalized. The constitution of 1837, however, included in its classification of Spanish subjects those who should receive letters of naturalization, and provided for the enactment of a law declaratory of the conditions upon which such letters would be granted. The present state of the law appears to be unsettled or difficult to ascertain. All that can be gathered is that 5 years' residence is necessary, that the applicant must be of the Roman Catholic religion, and that the right of a Spanish subject to renounce his allegiance is recognized by law.—In Sardinia any person who has resided in the country 5 years, and has purchased real estate or engaged in a useful commercial business, may apply to the minister of justice to be naturalized. The application is referred to the councillors of state, and if they report favorably letters of naturalization are granted, which must be signed by the monarch. These conditions must be complied with in every case; even the king has no power to dispense with them. In the Papal States, the pope may naturalize any

person he thinks proper. It is a power, however, but rarely exercised. The usual course is to grant it after 5 years' residence, in cases where the applicant has purchased real estate, or has engaged in some useful commercial business. In the Neapolitan dominions, previous to the changes consummated in 1860, the king, as in the Papal States, naturalized whom he thought proper; but the exercise of the power was very unusual. The general mode was the same as in the Papal States. In Naples and the Papal States none could be admitted but Catholics; but in Sardinia no distinction is made on the ground of religion. The policy of the several Italian states and the disposition of the people are averse to naturalizing foreigners. Every case, even in Sardinia, is closely scrutinized. In 1850, in consequence of extensive emigrations into Sardinia from Lombardy, Naples, and the Papal States, a special act was passed dispensing with the qualification of residence in respect to this class of Italians; but the law has since been repealed. In the republic of San Marino, naturalization is granted without residence on the payment of \$10, the republic engaging to give protection for three weeks to any naturalized citizen taking refuge there.—In Greece the policy of the government has been absurdly restrictive. The course pursued with respect to the disposition of the public lands, and the immigration and settlement of the Greeks of the islands and the Turkish provinces, has been such that no encouragement has been held out to this large body of the Hellenic family to quit the miserable and tottering empire in which they have been so long oppressed. The consequence has been that the population of the kingdom is at present but little over a million, when it might have been two or three millions under a liberal system. The 3d article of the constitution of 1843 defines citizens (*πολιται*) to be those who have acquired or may acquire the characteristics of a citizen according to the laws of the kingdom; and the national assembly that formed the constitution passed a decree, to be of the same force and effect as if incorporated in that instrument, by which it was declared that the government should neither retain nor appoint to places in the public service those who were not embraced in the following classes: 1, the native inhabitants of the Greek state, and those who took part in the struggle for independence to the end of 1827, or who came to Greece and remained there until the end of that year, and those who took a military and decisive part in battles with the enemy by sea or land up to 1829; 2, those inhabitants and combatants of continental Greece or of the islands, who took up arms in the war of independence, and who up to 1837 came and established themselves in one of the demes (districts) of the kingdom; and the descendants of the above classes. Those who established themselves in the kingdom between 1827 and 1833, are declared eligible in two years after the publica-

frequently to have led the Israelites astray; and Saul, after having, in obedience to the divine command, "put away those that had familiar spirits and the wizards out of the land," procured the woman of Endor to evoke the spirit of Samuel, saying to her: "Bring me him up whom I shall name unto thee." (1 Sam. xxviii. 3-8.) Isaiah denounces also those who sleep upon tombs for the purpose of having communications from the departed by means of dreams; and, as if to prevent any attempt at evocation of the departed, the Jews were taught to consider simple contact with a dead body unclean. The establishment of the Christian religion brought the necromancer, whose occupation in an earlier age had been of a religious character, or at least a lawful one, under the ban of the church; and the emperor Constantine, while he permitted the pagan priesthood upon certain occasions to consult their augurs, prohibited under severe penalties the evocation of the dead. Julian the Apostate, however, subsequently encouraged the practice, which was so common among the unconverted in the early history of the church, that, according to Mr. E. Rich, as appears from passages in the writings of the fathers, one object of the experiences to which the Christian neophyte was subject, was his introduction to a lawful communion with the spirits of the departed. The necromancer of the middle ages seems to have been merged in the sorcerer, who practised what was called the "black" or "forbidden art," and summoned not merely the spirits of the dead, but, by means of potent spells, demons and infernal spirits whose presence was full of danger and terror to the evoker. As late as the close of the 15th century public schools of necromancy are said to have been in existence in Seville, Toledo, and Salamanca, in caverns and other subterranean retreats, the entrances to which Isabella the Catholic caused to be securely walled up.—The latest form of necromancy will be found treated under the head of SPIRITUALISM. See also MAGIC.

NECTAR, according to the Greek and Roman mythologists and poets, the beverage of the gods, imparting health, vigor, youth, and beauty to all who drank it. It is described as a red wine, which like that of mortals was drunk mixed with water. It was served at the banquets of the immortals by Hebe or Ganymede. According to a few ancient writers it was the same as ambrosia, being not the drink but the food of the gods. In the Iliad, Thetis is represented as preserving the body of Patroclus from decay by anointing it with both ambrosia and nectar.

NECTARINE, a fruit considered by botanists as in no way distinct from the peach except in its having a smooth skin. It is the product of the *amygdalus Persica*, variety *lavis* of De Candolle, and like its parent species occurs in two sorts, viz.: the freestone nectarine, with the flesh parting from the nut, and the clingstone nectarine, with the flesh adhering to the

nut. The best varieties are known under the names of early violet, Elruge, Boston, Hunt's tawny, Roman, &c., requiring the same treatment in cultivation as is appropriate to the peach. Royle, in his "Illustrations of Botany," &c. (London, 1889), mentions the nectarine as being seen in the gardens of northern India, where it is called the smooth peach; but from whence it was introduced is uncertain. In the northern part of the United States the nectarine is sometimes forced in peach houses with success; and some of the hardier sorts will thrive in the open air.

NECTARY, a term now in disuse, employed by the Linnæan botanists to designate that part of the flower which secretes a sugary fluid similar to or precisely the same as honey. The use of this fluid was supposed to be that of attracting insects, so that fertilization might be rendered certain by their rubbing their bodies against the pollen grains and thus transferring them to the stigmata. This idea is now abandoned, and the nectary is not considered an essential or distinct organ, the secretion in question differing in no particular functional aspect from other secretions in other parts of the plant. Malpighi in 1671, Tournefort in 1694, and Vaillant in 1718 noticed this honeyed secretion in particular parts of flowers; but the last especially did not regard the parts as deserving any distinct name. Linnæus, however, in 1750, in his *Philosophia Botanica*, claims the merit of having first detected and exposed these organs. With him the corolla of a flower consisted of the petal and the nectary; the latter was called the melliferous part peculiar to the flower. Frequently it was only a gland or glandular bodies in the bottom of the calyx, at the base of the petals or stamens, as in *berberis*, *caltha*, and the siliqueous plants, *erica*, *fuchsia*, &c.; or scales in the base of the corolla, as in *sedum* and *crassula*; or a sort of pitcher (*urceolus*) in the same position, as in *eucomis* and *ruscus*; or a fleshy ring surrounding the germen, as in *nicandra*, *crocus*, and *salvia*; or the base of the petals becoming a sort of fleshy gland, as in *fritillaria*; or pits in the tube of the corolla or in the petals, as in *hydrophyllum*; or processes from the stamens, as in *viola* and *fumaria*; or pores on the ovary, as in *acilla* and *ruta*; or a swelling of the bottom of the corolla, as in *lonicera* and *antirrhinum*; or sub-tubular, honey-bearing claws, as in *myosorus* and *ranunculus*; or a terminal spur, as in *aquilegia* and *impatiens*; or the labellum of the *orchis* family was considered the nectary, and even the cup of the *narcissus*. The nectar itself was guarded by the *nectarilyma*, in the shape of hairs, scales, rings, connivent and concrete anthers; or lodged securely in the *nectarotheca*, pocket-like swellings; or designated and pointed out to insects by the *nectarostigma*, in the forms of spots, lines, or processes of more vivid tints.

NEEDLE, a slender steel instrument, pointed at one end and with an eye at the other,

used for carrying the thread in sewing. Among uncivilized people, at a very early period, rude attempts were made to form needles or bodkins of bone and ivory, by means of which their garments might be stitched together. The use of needles was known to the ancient Egyptians, a few having been found in their tombs. These were of bronze and of large size, being from 8 to 4 inches in length; but Wilkinson states that such as were employed in their fine work must have been of a very minute kind. Pliny mentions needles of bronze for sewing and knitting as being in use in his day. The Spanish or steel needle was introduced into England in the time of Queen Elizabeth; but the process by which it was made was kept secret, and the art was unknown until the year 1650, when it was again revived by Christopher Greening at Long Orenden in Buckinghamshire. Great improvements have since been introduced in needle making; and the "fine steel needles" of that period bear but a faint resemblance to the delicate and highly tempered needles of the present time. The manufacture of needles is now carried on to a great extent in many villages in England, but principally at Redditch, about 14 miles from Birmingham; and from this obscure place a large portion of Europe, the British colonies, and the United States are supplied. They are also made at Aix la Chapelle and at Borcette, a town not far distant, the latter place being the principal seat of the manufacture on the continent.—Though extremely simple in its form and appearance, the needle requires a multitude of operations for its construction, passing through the hands of nearly 100 workmen. The wires of various sizes being furnished in coils to the needle maker, he selects such as are of equal diameter and clips them into pieces, each of the length of two needles, with large shears, which are fastened to the wall of the cutting room. These, being cut from the coil, are of course more or less bent. To straighten them, many thousands are enclosed within a couple of rings, and, after being heated to redness, are laid, still retained in the rings, on an iron plate. The workman then takes what is called a smooth file, having two slots cut lengthwise in it, into which the edges of the rings are inserted. Holding this instrument by the ends, he rolls the rings backward and forward until the wires by their friction against each other become perfectly straight. The wires are next pointed by applying them to small, rapidly revolving grindstones. A workman is seated by each stone, holding in his left hand a number of wires, so arranged that the ends project slightly over the fingers and hand, and by a peculiar motion of the right hand he so rolls the wires over the stone as to produce a symmetrical point, occasionally dipping them in water to keep them cool. This operation soon ruins the health of the grinder, the fine dust from the steel penetrating the lungs, and producing a disease known

as "grinders' asthma." A physician in Redditch has observed during a long practice that out of many thousand men employed in pointing, scarcely one reaches the age of 40. Many ingenious methods have been contrived to remedy this evil, but the grinders are unwilling to adopt them, as by lessening the risk they fear a decrease in their wages; and the only precaution they take is that of tying a large handkerchief over the mouth. The needle manufacturers are now introducing ventilating shafts which purify the air from the injurious dust. The wires being pointed at both ends, the centre of each is flattened, and a groove is formed on either side, with a small indentation at the spot where the eye of the needle is to be made, which operation is performed by means of a stamping machine. A bed of iron which contains the under half of the die or stamp is supported on a heavy stone, the upper half being attached to the bottom of a hammer, of about 12 lbs. weight, which is raised with the foot by means of a lever. The wires are dropped, one at a time, upon the iron bed, and the hammer is made to fall upon them with a sharp blow. The raised faces of the stamp produce indentations on the opposite sides of the wire; and though the operator adjusts each piece separately, yet he can stamp 2,000 wires or 4,000 needles in an hour. The work of eyeing the needles is performed by boys, who use small hand presses for the purpose. The needles are arranged in the form of a fan, and placed on an iron slab. The upper arm of the press is provided with a couple of steel points or cutters which are brought down to punch the eyes, the boy constantly moving the wires in his hand so as to bring a fresh one under the cutter. So expert do they become in this business, that it is said they can pierce one human hair and thread it with another. Another method is sometimes adopted for eyeing the needles. The wires, after being pointed at the ends, are cut in two, and laid parallel to each other in boxes. The head of each separate wire is then flattened with a small hammer on a block of steel, which hardens it so much that it is necessary to soften it by heating before the eye can be made. The piercer, who is generally a child, then places the ends on a block of steel, and with one blow of a hammer by means of a sharp punch pierces the eye. The needle is turned over and the operation repeated in order that the two sides may be alike. The groove is formed afterward by means of a small file. This method is little practised, being neither so economical nor so expeditious as that first described. In the former process, after the wire is perforated, the needles are strung on fine wires, and the bur formed by stamping out the eyes is filed off. The lengths are next separated between the eyes by bending the lines of needles backward and forward. The points then being held firmly in a hand vice, the heads are filed to their proper shape. This completes the soft

work, as it is called. The next process is hardening. The needles are now in a black, soft, dingy state; and in order to harden them they are placed on iron plates and brought to a red heat, when they are plunged into cold water or oil, after which they are again heated to a less temperature and more gradually cooled. Meanwhile, they are kept in constant motion until, changing to a blue color, they are seen to be of the proper temper. Such of the needles as have become distorted are detected by rolling them upon a smooth steel surface with the finger. These are straightened by being tapped upon an anvil with a small hammer. The scouring or cleaning is accomplished by laying the needles in heaps upon pieces of canvas, scattering upon them a quantity of soft soap, emery, and oil, and rolling them into bundles which are secured by being closely wound with twine. Each bundle is from 2 to 3 feet long and from 3 to 4 inches thick. These are placed in a scouring machine, which resembles a common mangle, and rolled backward and forward for 50 or 60 hours. The canvas becoming worn requires renewing every 8 hours, and fresh polishing materials are then added. The scouring and cleaning is continued for the best needles 7 or 8 days. When taken out of the canvas they are laid on tin plates, and a little girl is employed to place the heads all one way. This is done simply by wrapping a piece of wash leather around the fore finger, and pressing it against one end of the pile of needles, thus catching all the points which lie in that direction. All the imperfect needles are then removed, the remainder are placed in rows upon metal plates with the eyes projecting over the edge, and a red-hot iron plate is brought sufficiently near to produce a dark blue film upon the heads, which indicates a proper temper. The very delicate operation of drilling, or removing the jagged portions from the interior of the eye, follows. This is performed by a woman who has before her a 3-sided steel drill, revolving rapidly. Taking the needles in her hand and arranging them in the form of a fan, she brings them successively under the action of the drill, first on one side and then on the other, after bevelling off the sharp edge of the eye where it communicates with the groove, which is called counter-sinking. The drilling of the eye is a modern improvement, and requires a very steady hand. The points are finished upon a small rotating stone, and then polished on a wheel covered with buff leather, slightly coated with polishing paste. Lastly they are counted into quarters of hundreds, folded in colored papers, and labelled. For exportation these are made up into packets containing from 20,000 to 60,000 each. The processes above described apply only to the finer sorts of needles. In the heavier kinds, such as harness, upholsterers', sail, mattress, and book-binding needles, many of these operations are omitted. The French needles are generally made of iron wire which

is converted in the course of the process by cementation into steel. The manufacture by this method is less difficult, but the needles are decidedly inferior to the English.—The imports of needles into the United States in the year ending June 30, 1859, amounted to \$254,794, of which \$217,884 were from England.

NEEDLES, THE, a cluster of 5 pyramidal rocks in the English channel, lying off the W. extremity of the isle of Wight. They are composed of thick strata of chalk alternating with very thin strata of black flint. The waves are continually producing changes in their form. About 80 years ago the principal one, which was 120 feet in height, fell down, and almost entirely disappeared.

NEEF, or NEES, PETER, the elder, a painter of the Flemish school, born in Antwerp in 1570, died in 1651. He was a disciple of Henry Steenwyck the elder, and like him was distinguished for his excellence in perspective and architectural views. He painted principally the interiors of churches and temples, and with such skill and delicacy that the most magnificent edifices would be represented in the small space of a cabinet picture, and the various decorations finished with the utmost precision and correctness. Many of these views are represented by torchlight. As he was deficient in designing figures, he often employed the Francka, Van Thulden, Jan Breughel, or Teniers to paint them; and his pictures, decorated by the two last, are consequently greatly enhanced in value.

NEELE, HENRY, an English poet and miscellaneous author, born in London, Jan. 29, 1798, committed suicide, Feb. 7, 1828. He was the son of an engraver in the Strand, and in early life was articled to an attorney. Before his clerkship had expired he published a volume of poems, remarkable for their melancholy character. In 1827 he delivered a series of lectures on English poetry from Chaucer to Cowper. His other works are: "Dramatic Scenes," "The Romance of English History," and "Literary Remains," published after his death. He was engaged upon another work, when his intense application to study brought on a fit of insanity, during which he killed himself.

NEEMUOH, a town of Hindostan, in the territory of Gwalior, built on rising ground near the boundary between Malwah and Mewar, 871 m. S. W. from Delhi; pop. about 4,000. It is an important British military station, and has an extensive cantonment and a small fort. A mutiny of native troops took place here, June 8, 1857, and on Nov. 8 the British garrison was attacked by 5,000 rebels, who besieged them ineffectually for about a fortnight, and were finally driven off after attempting an assault.

NEES VON ESENBECK, CHRISTIAN GOTTFRIED DANIEL, a German botanist and naturalist, born near Erbach in the Odenwald, Feb. 14, 1776, died March 16, 1858. He was educated at the gymnasium of Darmstadt, and from

1796 to 1799 at the university of Jena, where he studied medicine and the natural sciences, and became acquainted with Fichte and Schelling. After practising for a time as a physician, he was appointed in 1818 professor of botany at Erlangen, and in August of the same year was elected president of the Leopoldine academy of naturalists. In 1819 he was called to the newly founded university of Bonn, and with the help of his brother laid out the botanic garden there; and in 1830 he went to Breslau as professor of botany and director of the botanic garden. The latter years of his life were disturbed by his participation in the revolutionary movements in Germany. In 1848 he went to Berlin, but was exiled from that city in Jan. 1849. In Jan. 1851, he was suspended from the professorship in the university of Breslau in consequence of his connection with a political society called the fraternity of laborers, and by a royal decree was deprived, March 13, 1853, of his office. Without property, suspected by government, and surrounded by a numerous family, he was obliged to rely for support on the aid of his friends, and to sell his valuable library, and his herbarium, consisting of 80,000 specimens. One of the most distinguished of German botanists, he was honored with numerous dignities, and was elected a member of 77 learned societies. Goethe, in his "Metamorphosis of Plants," had advanced the theory that the various parts of the flower are all modifications of one common type, the leaf; and this theory Nees von Esenbeck demonstrated to be scientifically true in his *Handbuch der Botanik* (3 vols., Nuremberg, 1830-'31). Among his other botanical works are: *Die Algen des süßen Wassers* (Bamberg, 1814); *Das System der Pilze und Schwämme* (Würzburg, 1816); *Die Pflanzenweltansichten*, written in conjunction with Bischof and Rothe (Erlangen, 1819); *De Cinnamomo* (Bonn, 1828); *Bryologia Germanica*, with 43 colored plates, in conjunction with Hornschuch and Sturm (2 vols., Nuremberg, 1823-'31); *Agrostologia Brasiliensis*, forming the first part of Martius's *Flora Brasiliensis* (Stuttgart, 1829); *Enumeratio Plantarum Cryptogamicarum Javæ et Insularum adjacentium* (Breslau, 1830); *Genera et Species Asteroacearum* (Nuremberg, 1833); *Systema Laurinarum* (Berlin, 1836); *Flora Africa Australioris Illustrationes Monographica* (Glogau, 1841); and *Systema Hepaticarum*, in conjunction with Gottsche and Lindenberg (Hamburg, 1844-'7). He began his long projected illustrated manual of universal natural history with a volume entitled *Die allgemeine Formenlehre der Natur* (Breslau, 1852). He early applied himself to the study of cryptogamous plants, in regard to which his researches were minute and extensive. His great work in this department is the *Naturgeschichte der Europäischen Lebermoose*, also mentioned under the title of *Erinnerungen aus dem Riesengebirge* (4 vols., Berlin and Breslau, 1833-'38). In the latter part of his life he devoted himself to speculative thought, and

published (1841) *Die Naturphilosophie*, which he intended as the first part of a "System of Speculative Philosophy."

NEFF, FELIX, a Swiss missionary, born in Geneva, Oct. 8, 1798, died there in 1829. He early entered the army, and was advanced to the rank of sergeant; but forsook the military career in 1819 to become a missionary in the valleys of the upper Alps. In 1821-'2 he visited the destitute districts of Grenoble and Mens in France; and in April, 1823, went to England, where he was ordained an Independent minister. After returning to Switzerland he resumed his labors in the Alpine glens, dedicating churches, organizing schools, and aiming incessantly to benefit the people; and the hardships to which he subjected himself finally destroyed his health. His life has been written by A. Bost (London, 1855).

NEGOTIABLE PAPER, either promissory notes or bills of exchange, payable to a payee or his order. In the article EXCHANGE, BILL OF, some of the general rules of the law of negotiable paper have been stated. In explanation of the central principle and foundation of this very peculiar system of law, we will briefly consider its origin and history. The earliest commerce must have been by barter, and therefore limited to the exchange of superfluities between neighbors. Then money was invented and used as the representative of all value and all property; and he who had any thing to spare could exchange it for money, in which its value was vested, and this value could be retained by him who held it until he wished to exchange it for something he needed to use. It was an immense step thus to obtain a representative of all value; and the utility of it grew with the increasing commerce of the world, and was found adequate to the wants of this commerce until a few centuries ago, when the next step was taken, and something was found which is the representative of the representative of all value; and to this last invention the enormous increase of commerce since it came into use must be ascribed. As a bag of coin represented the value of 100 oxen, now a strip of paper represents the value of barrels of gold. But while the principal benefit of negotiable paper is due to the fact of this perfect representation of all value, there are two other utilities attached to it of almost equal importance. One of these is the facility it offers for paying distant debts without transfer of money or property, by making debts in one place pay debts in another, through the instrumentality of bills of exchange. The other is the method it offers of accumulating credit and employing the whole mass as money by means of successive indorsements. Such a transaction as a request by one in Rome to his debtor in Athens, to pay the debt to some one there whom the creditor in Rome owed, must have taken place often from the first beginnings of foreign commerce, as is intimated under EXCHANGE, BILL OF, where reference is made to the prob-

able origin and history of bills of exchange. We will add only, that the many and inconsistent theories which refer the invention to the Jews, who made use of it to transfer their property from countries in which they were threatened with persecution and robbery, to others where they were safer; to the Guelphic Florentines when they were exiled from Italy by the victorious Ghibellines; or to the Lombard merchants who were driven from country to country, perhaps for their oppressive usury, and more probably for their wealth; all of these only prove that about 6 centuries ago the bill of exchange came into use among merchants and capitalists in western Europe, and nothing more is certainly known about it. It was not until long afterward that negotiable promissory notes were used. Indeed, about the year 1700, a disinclination to admit them to the privileges of negotiability was so distinctly indicated by the English judges (chiefly by Lord Chief Justice Holt in 1702), that in 1704 it caused the statute of 3 and 4 Anne, ch. 9, by which it is enacted that they should be "assignable and indorsable over in the same manner as inland bills of exchange are or may be by the custom of merchants." It was by merchants, who could not but see the vast advantage of bills of exchange, that they were so firmly established as instruments of commerce, that the courts were compelled to recognize them. When, at a later period, the frequent use of negotiable promissory notes brought them before the courts, resistance was made; but the usefulness of the thing and the power of mercantile usage overcame this resistance, and in fact caused the enactment above referred to. The secret of this resistance lies in the fact, that the negotiability of instruments, from which the whole of their mercantile value is derived, is an absolute exception to, or rather comes into decided conflict with, the best established principles of the common law. To explain this, we must refer to the ancient rule, that no chose in action can be assigned. A chose in action (which means any debt, or claim, or interest not in possession of the holder) is only a right to recover something by an action, or, in other words, it is a right to go to law; and the courts, both of law and equity, had settled upon rules, of which the purpose and effect were to prevent the assignment or transfer of such a right of action, in a manner detrimental and unjust to the party sued. The assignee was obliged to bring his action in the name of the assignor. The reason was, that the assignee must hold the debt, subject to all the equitable defences, or equities of defence (by which legal phrase is meant defences grounded in equity), which the debtor might have. For example, if A owes B \$1,000 for goods bought, and gives B some receipt or other instrument showing this; and A soon pays B \$800, and then \$300 more; and B, not telling C of this, sells the debt to C as if it were still \$1,000, and C sues it; now if C sues in

the name of B, that is, if the action is B *vs.* A, there is nothing to prevent A from showing that he has already paid \$600. But if the action stands C *vs.* A for the original debt, there might be at least a formal difficulty in permitting A to show what he had paid B. It should be observed, that if, in the case supposed, C sues A in the name of B, A cannot set up as a defence any payment which he had made to B after he had notice of B's transfer to C, because this would not be equitable, but rather a fraud upon C. And it may further be remarked, that in those of our states in which the assignee of a chose in action may or must bring his action against the debtor in his own name, these equitable defences are all preserved to the original debtor. Now the rule is precisely otherwise in regard to negotiable paper. Here no equitable defences of this kind are permitted against a party who holds the paper by indorsement, and for value. This is what is meant by the negotiability of a promissory note; and it is secured by the words "or order." If A, in the case before supposed, gave B his note, promising thereby to pay him, without the words "or order," \$1,000 in 6 months, and saw fit to pay him the two sums of \$800 even in 2 and 4 months, and afterward B sold the note to C, A could show in an action against him what he had paid, and would be held to C only for the balance; for by such a note he promises to pay B \$1,000, and does not promise to pay that sum to anybody else. But if the note promised to pay B "or his order," A has now given paper which may go forth into the community and pass from hand to hand, carrying his credit for the sum named with it; he promises now to pay the whole sum, not to B only, but to anybody else who owns the note by B's order, and who presents it to him at maturity. If therefore he chooses to pay B any part of the amount before maturity, without having the payment written upon the note itself, he pays the money at his own risk, and must lose it. And B exercises his right to order the payment to be made to another person by indorsing the note; that is, by writing his name on the back. A note or bill is said to be negotiable when thus payable to order, because by these words, or rather by this quality of transferableness which these words give, the note becomes capable of being used in business (the Latin word *negotium* meaning business), as an instrument of business; that is, as money itself could be used, or as the representative of money; and it is said to be negotiated, when it is so transferred by indorsement.—It is a perfectly well established rule of law, made in fact inevitable by the nature and use of money, that money, or coined gold and silver, differs from all other property in the following particular. If a man loses his watch or is robbed of it, and the finder or robber sells it for value to a perfectly innocent purchaser, who sells it to another, and he to another, and so on, the

owner can take it wherever he can find it, for no buyer acquires the slightest property in it against the owner. But if a man loses or is robbed of gold coins, and the finder or robber pays them away to an innocent party in the purchase of goods, the owner loses his money. He cannot reclaim it unless by proof that the receiver of it knew when he took it that it belonged to some one other than the holder. Now this is precisely so in relation to promissory notes or bills of exchange, payable to order or to bearer. A familiar example may be found in bank notes, which are only promissory notes payable to bearer, and which stand exactly on the footing of coined money, in that any one receiving them innocently, for value, holds them against any original owner. For a while the law was, in England at least, that one who purchased negotiable paper "under suspicious circumstances" could not hold it against a true owner, or recover from promisor or indorser. But the merchants and bankers of London convinced the courts (so says Lord Campbell in his "Life of Lord Chief Justice Tenterden") that this rule was a very dangerous one; and after a while the law was established there, as it is here, that nothing is a defence against a holder for value but proof of actual fraud; that is, proof that he took it with actual knowledge that the party from whom he took it had no property in it, and no right to transfer it. In *Goodman vs. Harvey* (4 Adolphus and Ellis, 870), Lord Chief Justice Denman says: "We have shaken off the last remnant of the contrary doctrine." And why? In order that negotiable paper might become the adequate instrument of business, as the word negotiable implies; and for this end that it might represent money, and take the place of money, and possess in all the transactions of business all the immunities and privileges of money. If we understand clearly this principle and purpose of negotiable paper, or rather of the rules of law in relation to negotiable paper, we shall be able to understand those rules. It is for this purpose that all those rules aim at giving to negotiable paper the certainty of money; of making it tell its own story as money does; and, in few words, of enabling every person who holds it to use it precisely as he would use money, with the additional advantage that he may, by his indorsement, add his own credit to that which the paper already holds. It is to a misapprehension of this principle and purpose that we owe very much of the conflict and uncertainty still hanging over some parts of the law of negotiable paper. These rules are numerous. They form a beautiful, but an extensive and an intricate system. Even an indication of all of them, sufficiently full to be intelligible, would occupy more space than we can give to this subject. That part of this law which refers especially to bills of exchange has already been treated of under that head. In the present article we shall endeavor to give only those general rules

and fundamental principles which will enable any one not only to form a good idea of the whole system, but to answer almost any question which may arise in reference to it.—Mr. Ohitty says that the most usual form of a negotiable promissory note in England is: "£50 (or other sum). London, 1st Jany. 1860 (or other place or date). Two months after date (or on demand, or any other specified time), I promise to pay to Mr. A. B. or order fifty pounds, value received. (Signed) C. D." A more common form in America is: "New York, Jany. 1st, 1860. Value received, I promise to pay A. B. or order one thousand dollars in two months. C. D." But no especial form is necessary. The essential things are, a distinct promise, and sufficient certainty as to the payee, the payer, the amount, and the time of payment. And we must remember that the one purpose of all these certainties is to make the note, as far as the law can make it so, the absolute equivalent of money. As to the certainty of the payee, he may be either the original payee, or one who is made a payee by the indorsement of an original payee or of an indorsee; for every indorsee may become an indorser. If the note is not payable to bearer, nor to any payee by name or description, it is not a promissory note; but it may be payable "to the trustees under the will of (or the executors of the will of) A. B., or their order;" for such description defines them as well as a name. If it be payable to A or B it is bad, because it is not certain which is the payee. Of the certainty as to the payer, he must be, first, the maker, and then the indorsers in their order. He must be distinctly designated; and if it be signed in the alternative, "A or B," it is not enough. It has been held that signature by pencil, and even by initials, was sufficient. But we think these decisions forgetful of the purpose of negotiable paper, which certainly ought, in our judgment, to be signed in the ordinary way, if the paper is to be used in the ordinary way of transacting business. As a promissory note, like a bill of exchange, is intended to be the equivalent of money, it should be payable in money. On this point there is a singular difference between the law of England and that of some of the United States. There, bank of England notes are a lawful tender, excepting when paid by the bank itself, which is bound to give specie; and yet paper promising to pay "in cash or bank of England notes" is not negotiable, because not payable in money. Similar doctrine is held in Massachusetts, Vermont, Pennsylvania, Tennessee, Michigan, and perhaps some other states. But in New York, Ohio, Alabama, and Arkansas, it is sufficient if they are payable in "good current bills of the state," and in some states even less accuracy than this is required.—We proceed now to speak of indorsement; first premising, that an acceptor of a bill of exchange stands in the same position as the maker of a promissory note; while the drawer of a bill, who is re-

sponsible if the drawee refuses to accept, or to pay the bill, stands in the position of a first indorser. All that is said therefore of indorsement, of demand and notice, and liability, applies (this being understood) equally to bills of exchange and to promissory notes. Negotiable paper, we shall see, is often transferable by delivery; but it is by indorsement that it is properly transferred; that is, the payee, whether an original payee or one who is indorsee, writes his name on the back of the paper, and delivers it to him who is to be the holder. As this indorsement is the exercise of the right to order it paid, no one can indorse the paper who has not this right; that is, no one but a payee. And yet nothing is more common than for many parties to write their names one under the other, and then they stand as first, second, third indorser, and so forth. The explanation of this is, that the first payee, to whom or to whose order it is payable, may indorse it either in full or in blank. He indorses it in full if he writes, "Pay to A. B. or order," and then signs this; and now he makes A. B. the payee, and A. B. and nobody else can indorse it. But he indorses the paper in blank when he writes only his name with nothing over. As yet, then, he makes nobody the payee. But any one to whom he gives it, or any one to whom it is subsequently given and who becomes the lawful holder of the paper, may write over the name of the payee (or indorser) the name of any person whom he chooses to make indorsee. When he has thus filled the indorsement, the indorsee alone can indorse it further. Now if a note has on its back the names of A, who is payee, and then B, then C, then D, &c., if E buys the note and sues it, he may write "Pay to B" over A's name, and "Pay to C" over B's name, and so on, and over the last indorser, "Pay to E." Thus the title is deduced to him, and all the previous parties are liable to him. For it is to be remarked, as of the essence of negotiable paper, that as A promises by his indorsement to pay if the maker does not, so B promises to pay if neither the maker nor A pays, and C promises to pay if neither the maker nor A nor B pays, and so on. In this way the accumulated credit of all the names is added to the note, because every person who signs the paper holds the guaranty of all before him, and is the guarantor of everybody who signs before him to all who come after him. It must be further remarked, that E, in the above case, may write over A's name, "Pay to E," and then he has good title to the note from A, and may hold him and the maker liable. But he can hold no one else. He has taken away the right of B to indorse, because he has made A indorse to E and not to B; and if B could not indorse legally, neither could C nor D. Thus a holder of paper with blank indorsements may select whom he will and discharge whom he will, by filling the indorsements so as to derive his title only from those

whom he chooses to hold. There is, however, one important exception to this. In the case above supposed, E could not make title by filling indorsement from A to B, and from B to D (omitting C), and from D to E, and so hold D. The reason is, that by omitting C he has not only deprived himself of the power of calling on C, but he has deprived D also of this power; and therefore E shall not himself hold D. For every indorser has a right to look to every party before him, that is, to the maker and every prior indorser; and if a holder chooses to discharge any of these, he cannot hold any subsequent party, because he has lessened the guaranty to which that subsequent party may look. From what has been said, it will be seen that paper indorsed in blank is as much transferable by delivery as paper promising to pay to bearer; and if one holds paper indorsed in blank, or payable to bearer, and transfers this for value, by delivery only, without any indorsement or guaranty, he cannot be made liable for it. But paper payable to bearer cannot be indorsed with the same effect as paper payable to order, because there is no distinct payee. It is now common in our large commercial cities for sellers to take notes payable to the maker himself or his own order, and indorsed by him. Such notes can now be indorsed if any holder chooses to do so, or, if sold or discounted, can be transferred by delivery only. As indorsement has a twofold operation, first to transfer the paper, and then to guarantee its payment, these two operations may be separated. If an indorser writes over his name any refusal to guarantee, he passes the paper, but cannot be called upon. The usual way of doing this is by the words, "Without recourse," the rest of the sentence ("to me in any event") being supplied by law and custom.—It is much disputed what is the effect of indorsement by one not payee or indorsee; and the law on this subject differs in different states. Perhaps the law and the prevailing rule is, that if such a person writes his name on the back of a note when or before it is made or delivered, he may be held as if he wrote it on the face, that is, as maker; if after it is made and delivered, he may be treated as a guarantor, or the payee, if he elects to do so, may write his own name, or authorize a holder to write it, on the paper over the name already there, and thus make that the name of a second indorser.—It has been said, under EXCHANGE, BILL OF, that a bill imports value or consideration; and this is also true of a promissory note, whether the usual words "value received" be inserted or not. But a promissory note or bill, although not negotiable, differs from other contracts, not because it proves its own consideration or value, for it does not, but because it raises a presumption of this, and therefore a promisor cannot defend against his promise by saying that there was no consideration for it, and so put the plaintiff to prove consideration; but he may defeat the claim and avoid his promise, if he

can prove that there was no consideration for it. But one of the most important peculiarities of negotiable paper is, that no party, maker or acceptor or indorser, can set up the defence of want of consideration, against any third party to whom it has been transferred for value without notice. It is precisely this, in fact, which characterizes negotiable paper and makes it the fitting instrument of business. A makes the paper, B, C, D, and E successively indorse it; and F, to whom E indorses it, need not inquire whether A or B or C or D received any consideration. They have put their names there, and that is enough. But if F sues E, the defendant may show that no consideration passed between him and F; because the rule of law is, that as between any immediate parties, that is, maker and payee, or indorser and indorsee, a defendant may show want of consideration from his transferee, the plaintiff, but cannot show this in defence against any distant party. The only exception to this rule is where the distant party took the note with notice of the want of consideration, and also that this want constituted a defence; for it is no defence where the paper is accommodation paper. Thus, if A, at the request of B, and without consideration, indorses his note for the purpose of lending him his credit, B cannot sue A; but any party, distant or near, who gets the paper for value, may sue A, even if such party knew the want of consideration, because he would have a right to consider A as intending to lend his credit. In some states there is some disposition to say that a purchaser of accommodation paper shall recover from the accommodation maker or indorser only so much as the purchaser paid for it; and this rule has been applied in some courts even to the purchaser of negotiable paper not accommodation. But if it were an honest transaction, the prevailing, and we think the better rule is, that he recovers its face.—As soon as negotiable paper has been dishonored, or is over due, it loses almost the whole of its peculiar character, and what may be called its privilege. The reason is the obvious one, that it is no longer capable of negotiation in the proper sense of the word; that is, it is no longer fit to be an instrument of business: first, because it is already discredited, and cannot be considered the equivalent of money; and next, because there is no longer any time fixed when it can be paid or converted into money. Hence it is now like paper not negotiable; that is, it may be sold or transferred as before, but the purchaser takes it now subject to the defence which could be made against it if it were still in the hands of the first party who transferred it after dishonor. Every indorser, including the drawer of a bill, who, we have said, holds the position of a first indorser, guarantees to a holder all prior parties; but this is only on condition that the holder does all that should be done by him to obtain the money from the prior parties, and to protect the interest of the parties looked to on

their guaranty. This condition is absolutely and always implied by law; and the rules which grow out of it are of very great practical importance. They determine when, where, by whom, and in what way acceptance shall be requested, and payment demanded, and notice of non-acceptance or non-payment given to all parties entitled to notice.—A bill of exchange should be presented for acceptance during the usual hours of business. The drawee may answer at once, or he may take a day for consideration; but if he does not accept before the end of the day after presentment, he refuses to accept. If not accepted absolutely, but upon some terms or conditions, the holder may assent to these, and then hold the acceptor; but he must treat it as no acceptance and give notice accordingly in order to hold the drawer. When a bill is accepted it becomes like a note; and every bill and every note must be presented for payment, or in other words, payment of them must be demanded, and the demand must be such as the law requires, or all parties except the maker or acceptor are discharged. The paper must be so presented and demanded at maturity, by the holder or his authorized agent, of the acceptor or maker, on the very day on which it falls due, and in the usual and proper business hours of that day. Neither the bankruptcy, nor the insolvency, nor the absence, nor the death of the acceptor or maker is a sufficient excuse for not making the demand. For the insolvent may pay it, and if the payer is absent the demand must be made at his house or residence, or at his place of business; and if he be dead, it must be made of his executors or administrators. If the holder dies before the paper matures, and his executors or administrators are not appointed until after the paper matures, they must make the demand as soon after as they can; and if they make it without unreasonable delay, it is sufficient. Generally, when the demand cannot be made in the usual way at the time, the law permits the demand to be made within a reasonable time after the obstruction is removed. If the payee has absconded, or has no place of residence or business in the state, or is absent and cannot be found by diligent inquiry, demand is excused. But the same notice must be given of this non-demand as of non-payment; for the parties liable on the paper have not only a right to require demand upon all persons liable before them, but the further right to have notice given them if the paper be not paid. The purpose of this is to give them every opportunity of getting such security or indemnity as they can from the parties for whom they are to make payment. Once, the law said only that the notice must be given in a reasonable time; but now, all over the commercial world, the law itself defines this reasonable time. It requires that this notice be given on the day of non-acceptance or non-payment, or on the day immediately following. If the party entitled

to notice lives at a distance, the notice should be given by mail, and must be put into the mail on the day of dishonor or the next day, if there be such a mail, and otherwise into the first mail that goes. A personal notice is, in general, good wherever given. And it should be personal, or in writing left at the residence or place of business, if the person giving the notice (as the notary or agent) lives in the same town or city with the party to whom it is given. He may send it even then by mail, but takes the risk of its reaching the payer in season; but if it is sent out of town, he may send it by mail, and this risk is not on the sender.—As the holder has one whole day to give his notice, so every one receiving notice has the same indulgence. Thus, if a note with 6 indorsers falls due, and the indorsee makes due demand of the maker, he must give notice of the non-payment to his indorser (who is the 6th) on the next day. That indorser has also until the next day to notify the 5th, and so on. Hence the first indorser will not get notice until the 6th day after non-payment; but now he will be held not only to his indorsee but to all persons below him, because he has had his due notice. No person, however, is entitled to the delay of more days than his own single day. Thus, if the indorsee of the 6th indorser notifies his indorser on the next day, he holds him; but if that indorser neglects to notify others, and the holder, learning this, on the 8d day notifies all the rest, all are discharged but the 6th indorser. Hence, it is usual for the holder not to take the risk of this, but to send notice himself to all the persons whose names are on the paper. (See NOTARY PUBLIC.) There is no precise form necessary for the notice. It should however state with sufficient distinctness what the paper is, its dishonor, and who the parties are, and the purpose of the notice. After due demand and due notice have fixed the liability of parties, it remains in force, and there is no need of immediate suit. This right to demand and notice may be waived by any party entitled to it, and he may do this by any words of sufficient meaning; the usual way is by writing over his name when he indorses: "Waives demand and notice." It should be remembered that a waiver of notice is not a waiver of demand; although a waiver of demand is perhaps a waiver of notice.—The demand must be made when the note falls due, or to use the common phrase, at its maturity. But this is not at the expiration of the time when the note is made payable on the face of it. The law adds three whole days, which are called days of grace. At first, these were, as the name intimates, days of favor or mere indulgence; but usage, and now law, have converted them into an absolute right. In most of the states, statutes provide that all negotiable paper, not payable at sight or on demand, is entitled to three days of grace, unless it be expressly agreed otherwise. This is sometimes done, but not often; and the words used for

this purpose are, simply, "without grace." One distinction is important. These days retain so much of their original character of mere indulgence, that if the last day of grace falls on Sunday, or on any holiday on which payment cannot be demanded, it is now due, and demand must be made, on the Saturday or other day preceding. But if paper without grace, or any payment not entitled to grace, falls due on Sunday, or any other legal holiday, the payer now gains a day, because payment cannot be demanded until Monday, or the day after the holiday. When and in what manner negotiable paper should be protested for non-payment, and how payment may be made *supra* protest, or for honor, will be stated in the article PROTEST.—It should be added, that of late years some other instruments beside bills of exchange and promissory notes have been treated by courts as negotiable paper. Exchequer bills in England were so held; and then the bonds of foreign states, payable to the holder, were so considered. In the United States the same doctrine has been extended to state bonds payable to bearer and transferable by delivery; and in a recent case of much authority, it has been applied to railroad bonds. That it should be applied to the coupons on such bonds there can be no doubt. The effect of this doctrine is, that if a thief or finder of any of these instruments sells or transfers them for value to any person not having knowledge of his want of title, the purchaser would hold them against the original owner. Hence the not uncommon advertisements, that such instruments have been stolen or lost, and all persons are warned not to buy them because payment has been stopped, would have no effect against any person whom this notice did not reach. The law would be otherwise in relation to common bonds, or deeds, or any other instruments which were not negotiable. In that case, whether the notice was or was not given, the true owner would not lose his property by a sale or transfer by one who had no right to make it.

NEGRILLO, one of the 11 races of men enumerated by Dr. Pickering, corresponding to the pelagian negroes of Dr. Prichard, and the *negritos del monte* of the Spanish voyagers. They are tribes of small, woolly-haired blacks, found in the interior of many of the islands of the East Indian archipelago, and in the mountainous regions of the Malay peninsula; they occur as far west as the Andaman islands in the bay of Bengal, as far south as New Britain and New Guinea, and as far north as the Philippine islands; their traces may be seen in many islands where the tribes no longer exist, and they are believed by many ethnologists to have been the aboriginal inhabitants, afterward displaced by the Malay race; their interrupted geographical distribution indicates a more extensive area of occupancy than the race now presents. The stature is small, on an average not more than 4½ feet, and the figure lank and

slight; the complexion is darker than that of the Malays, but lighter than that of the negro; the black color has a purplish or reddish tint; the hair is rather woolly, but without the knotty closeness seen in the negro; the forehead is low, the nose flat, and the lower part of the face more prominent even than in the negro; the beard is generally absent; the eyes are small and brilliant; the abdomen is protuberant, as in other races subject to great irregularity in the supply of food. The *negrillos* go nearly naked, wearing only a strip of bark or vegetable fibre around the loins; they live in bands of 50 or 60 in woods and mountains, wandering about in search of food, and are generally enlaved or hunted like wild beasts by the Malays. They are for the most part very rude in their habits, shy and suspicious of strangers, but hospitable if kindly treated, and generally inoffensive; where not oppressed by surrounding races they are intelligent, cultivating the soil, living in cabins, having most of the useful animals and plants of the Polynesian, and making canoes of rather indifferent workmanship compared with those of the maritime tribes. They inhabit Vanikoro, the scene of the shipwreck of *La Pérouse*; Capt. Dumont d'Urville, in the *Voyage de l'Astrolabe*, mentions the remarkable peculiarity of a state of active war existing between the people of different districts, the chiefs remaining friends. M. de la Gironière, in his "Twenty Years in the Philippine Islands" (New York, 1854), devotes a chapter to the *Ajetas* or the *negrillos* of the island of Luzon. Making due allowance for exaggeration, these people must there present rather a brutish appearance; they are armed with lances of bamboo, palm bows, and poisoned arrows; their food consists of roots, fruits, and the scanty products of the chase eaten nearly in a raw state; their language seems a monkey-like jabber, though in some places they speak a dialect of the Malay; they are very active, fleet runners, and expert climbers. Having hardly any idea of religion, they have a great veneration for the dead and respect for old age; they are not polygamous; they seem to have no instruments of music; old persons, especially the females, are positively hideous.

NEGRO, a name properly applied to the races inhabiting the African continent, principally between lat. 10° N. and 20° S., and to their descendants in the old and new world; it does not include the northern Africans (like the Egyptians, Berbers, Abyssinians, Nubians, &c.), though in popular language, especially in the older writings, it comprises these and other dark-skinned nations, who are not, however, characterized by the crisp hair of the true negro; in some of the border countries there has been considerable intermixture of negro blood and dialects. The Hottentots in the south do not belong to the negro race. The term negro, therefore, is not synonymous with African, and is not a national appellation, but denotes an ideal type constituted by cer-

tain physical characters, such as are seen in the people of the coast of Guinea, viz.: black skin, woolly hair, flat nose, thick everted lips, and a prognathous form of skull. Negroes occupy about one half of Africa, excluding the northern and southern extremities, but including its most fertile portions. Out of Africa, negroes are found in the United States, the West Indies, Brazil, Peru, the Cape Verd islands, and Arabia. In Brazil, the Spanish West Indies, and the United States, they are mostly in the condition of slavery. They are rare in Europe, Polynesia, and Australia, and when found are not enlaved. Negroes were nearly unknown to the Hebrews and the Homeric Greeks; the Egyptians, however, about 2800 B. C., became acquainted with negroes through the conquests of their rulers, and represented them on their monuments as early as 1600 B. C.; for nearly 35 centuries the type has remained unchanged in Egypt. Negroes were unknown to the Greeks until the 7th century B. C., their Ethiopians being merely any people darker than the Hellenic, like the Arabs, Egyptians, Libyans, or Carthaginians, none of which are negroes. The typical negroes of the Guinea, Gold, and Slave coasts are generally rude and nearly naked savages, of a deep black color and ugly features; in the interior, many of the tribes, like the Fan and others visited within the last 5 years by Mr. Du Chaillu, and described in his work (New York, 1861), are fierce cannibals, but fine-looking, warlike, ingenious, and skilful in the working of iron. Those on the Slave coast are the most degraded, selling their neighbors to slave dealers. In the vast regions explored by Barth, Livingstone, Du Chaillu, and other recent travelers, there are many tribes, more or less savage, for an account of which the reader is referred to their works. The Caffres of South Africa may also be classed among negroes, as well as the fine and ferocious races of Mozambique and the E. coast of Africa.—The skin of the negro is soft and silky, dull cherry red in the infant and growing black very soon; it differs from that of the whites principally in the greater amount of pigment cells in the *rete Malpighii* (the epidermis being uncolored), and in the greater number of cutaneous glands. The hair, though called wool, does not present the characters of the latter, especially the imbricated projecting scales, and differs but little from that of the other races except in color and in its curled and twisted form; it is harsh and wiry, and, according to some microscopists, more or less flattened, grooved longitudinally, lying perpendicularly in the dermis and piercing the cuticle in this direction, the coloring matter being diffused throughout its substance, and, in a few instances, so imbricated as to be capable of felting like wool. The skull is long and narrow, with a depressed forehead, prominent occiput and jaws, a facial angle of 70 to 85 degrees, and an internal capacity of about 82 cubic inches; a peculiarity

of some negro crania, though by no means constant, is that the sphenoid does not reach the parietal bones, the coronal suture joining the margin of the temporals; the skull is very thick and solid, as would be indicated by the negro's favorite mode of fighting, both sexes butting like rams, and so flat that burdens are easily carried upon it. The stature of the negro is seldom 6 feet, and rarely below 5½; some of their figures are fine, especially the *torso*, and have been taken by Chantrey and other sculptors as models; in the female the development is so rapid that it is common to see childhood's natural grace combined with the prominent characters of maturity. Seen from behind, the spine usually appears depressed, owing to the greater curvature of the ribs; the nates are more flattened than in other races, and join the thighs almost at a right angle instead of a curve. Beside the characters already mentioned, may be noticed the projecting upper edge of orbit; broad retreating chin; great development of lower part of face; small eyes, in which but little of the yellowish white ball is seen; small, thick ears, standing off from the head, with a small lobe and a general stunted look; black iris; very wide zygomatic arches, giving large space for the muscles of the lower jaw; large and transverse opening of the nasal cavity. The pelvis is long and narrow, its average circumference being from 26 to 28 inches, instead of 30 to 36 as in the whites; this shape in the female, according to Vrolik and Weber, corresponds to the characteristic shape of the negro head; those writers consider it a type of degradation, as it approaches that of the *quadrumanus* in the more vertical direction of the iliac bones and their less width, in the smaller breadth of sacrum, and in the consequent less extent of the hips. The bones of the leg are bent forward and outward, the tibia and fibula being more convex than in Europeans; the calves are very high; the feet and hands are flatter; the heel bone, instead of being arched, is continued in a straight line with the other bones of the foot, causing it to project more behind; in consequence of the longer lever thus obtained, less muscular force is necessary in the movements of the feet, and the muscles of the calf are consequently less developed; the shoulder blades are shorter and broader; the muscles have shorter bellies and longer tendons, as is very evident in the legs and arms. Negroes have less nervous sensibility than the whites, and are not subject to nervous affections; they are comparatively insensible to pain, bearing severe surgical operations well; the effects of opium and other narcotics appear rather in the digestive, circulatory, and respiratory functions, than in the cerebral and nervous system; they are little subject to yellow fever, and more to yaws and other outaneous affections; they are generally very torpid under disease. They seldom have a fetid breath, but transpire much excrementitious matter by means of the glands

of the skin, whose odorous secretion is well known; there is also much oily matter in the skin. The negro flourishes under the fiercest heats and unhealthy dampness of the tropics, where the white man soon dies, withstanding the virulent endemics and epidemics of the country; and the race does not diminish, like the aboriginal American, in contact with civilization, unless cruelly or injudiciously treated. The senses are acute; the voice in the males is hoarse and not powerful, and in the females high and shrill. Albinoes are not uncommon among negro races in all countries.—The African negroes display considerable ingenuity in the manufacture of weapons, in the working of iron, in the weaving of mats, cloth, and baskets from dyed grasses, in the dressing of skins of animals, in the structure of their huts and household utensils, and in the various implements and objects of use in a barbarous state of society. Their religion consists in the worship of idols and fetiches, representing a supreme power which they all acknowledge; they believe also in good and evil spirits, in witchcraft, charms and spells, omens, lucky and unlucky days, &c.; they make fetiches of serpents, elephants' teeth, tigers' claws, and many similar objects, and reverence wooden images and sacred things, which they think have received a peculiar power from their divinities to drive away evil spirits, and protect them from danger, disease, and witchcraft. They make prayers and offerings to their idols, and have sacred songs, festivals, dances, ceremonies, and places; they sacrifice animals and sometimes human victims, especially during funeral obsequies; they have their priests and holy men, who are also magicians and doctors. They believe generally in an after life, without any distinct idea of retribution, and some tribes in the transmigration of the human soul into a gorilla, or other beast, bird, reptile, or fish; they have great fear of ghosts and apparitions; they become ready converts to foreign religions, whether Islamism, Catholicism, or Protestantism. Being very fond of music, they have many ingeniously contrived musical instruments, generally of a noisy character; they have a keen sense of the ridiculous, and are of a cheerful disposition; though cruel to their enemies and prisoners, and setting little value on human life, they are naturally kind-hearted, hospitable to strangers, and communicative of their joys and sorrows; the females are remarkably affectionate as mothers and children, and as attendants on the sick, even to foreigners. They are less dirty in their persons and dwellings than most other barbarous races. They are ready to receive instruction, and to profit by it up to a certain point; quick to perceive the beauty of goodness, they generally appreciate the services of the missionaries in their behalf, and, were not their teachings counteracted by the intoxicating drinks brought by traders, they would probably soon, in outward observances if not

in reality, merit the name of semi-Christian communities.

NEGRO, Rio. See Rio Negro.

NEGROPONT, or EGEPO (anc. *Eubœa*), the largest island of the Grecian archipelago, separated from the coast of Attica by a narrow strait (anc. *Euripus*), called in its northern part the channel of Talanti and in its southern that of Eubœa or Negropont. The island lies N. W. and S. E.; length 100 m., breadth from 6 to 26 m.; area, 1,454 sq. m.; pop. in 1856, 68,818. The narrowest part of the strait is spanned by a bridge. The E. coast of the island is rocky and precipitous, and the interior is generally hilly, being traversed by a mountain ridge culminating near Delphi at the height of 6,359 feet, and abounding in varied and picturesque scenery. There are no rivers, the only streams being mere brooks, but the soil of the plains and valleys is exuberantly rich; the island is well wooded; pasturage is abundant, and grain, wine, oil, and fruits are produced, beside small quantities of wool, cotton, and the products of the pine. There are copper mines and quarries of marble; iron is said also to exist. Agriculture has been considerably improved by foreign settlers, but the native population is generally very poor. There are several good harbors on the W. coast, and two towns, Chalcis or Negropont, the capital (see CHALCIS), and Karysto.—In pre-historic times Eubœa was colonized by Ionic Greeks, and was divided between 6 or 7 independent cities, of which Chalcis and Eretria were the most important. The whole island became subject to Athens after the Persian war, revolted in 445 B. C., was reconquered by Pericles, revolted again in 411 B. C., and from the time of Philip of Macedon was a portion of the Macedonian dominions, until the Romans in 194 B. C. made alliances with its chief towns, and enabled it to recover its independence. It fell, however, under the Roman yoke when Antiochus invaded Greece, and on the dissolution of the Byzantine empire was occupied by the Venetians. Mohammed II. took it from them in 1469. It now forms part of the kingdom of Greece, constituting together with the northern Sporades the province of Eubœa.

NEHEMIAH (Heb., whom the Lord consoles), a Jewish governor of Judæa, under the Persians, and cup-bearer to King Artaxerxes Longimanus. He was the son of Chalkiah, received the surname or title of Tirshatha, and is the author of the scriptural book which bears his name, a continuation of the historical book of Ezra. The dates of his birth and death are unknown. In the history of his people, in which he played a prominent and noble part during the period of the restoration under the Persians, he first appears in 444 B. C. (See HEBREWS, vol. ix. p. 87.)

NEILGHERRY HILLS, or NEILGHERRIES (Blæ mountains), a remarkable mass of mountains in S. Hindostan, connected with the western Ghats, about 60 m. E. from Calicut.

They lie between lat. 11° 10' and 11° 28' N., and long. 76° 30' and 77° 10' E.; their greatest length at an elevation of 5,000 feet is 42 m., and their area at the same height is about 500 sq. m. The region to which they belong was transferred to the British in 1799 on the downfall of Tippoo Sultan. The surface of the mountains is undulating, varying from 6,000 to 7,000 feet above the surrounding plains, with some grand peaks rising up at intervals. Dodabetta, the highest of these, and the loftiest mountain in India S. of the Himalaya, is 8,760 feet above the level of the sea. The Neilgherries are composed of granite, which is covered with a rich black soil, often 10 feet deep in the valleys; there are some morasses, many of them consisting of peat, which makes excellent fuel. The base of these mountains, which covers a surface of some 200 m. in circumference, is clothed with a dense forest, swarming with wild animals of all descriptions, among which elephants and tigers are numerous. This barrier forest is exceedingly unhealthy, and for ages the great difficulties and dangers attendant upon passing it isolated the mountains from the surrounding country, and prevented their being explored. About 80 years ago two British officers succeeded in crossing the jungle and ascending the hills, and were rewarded by discovering a fine open grass country, with the vegetation of temperate regions. It was intersected by numerous streams, well stocked with cattle, and inhabited by a strange race quite different both in appearance and language from all others of Hindostan. These people are of a light complexion, have strongly marked Jewish features, and have been supposed by many to be one of the lost tribes. They build their houses in a peculiar manner, subsist chiefly upon the produce of their cattle, are tall, well formed, and handsome, but are very filthy in their habits. The mean temperature at Ootacamund, 7,800 feet above the sea, is 58°. A considerable town has sprung up at this place, in lat. 11° 24' N., long. 76° 47' E., near the centre of the plateau, and is frequented by European invalids from other places. There is another town on the Neilgherries, named Koonoor, at an elevation of 6,000 feet, where the climate is not quite so cold. The late Lord Elphinstone built an elegant mansion near the road between these towns, which is now occupied as a mission school for the education of children from the plains of European descent. All the fruits and vegetables of the temperate regions attain great perfection, and are cultivated for markets 200 and 300 m. distant. In places there are patches of strawberries growing wild several acres in extent. There are no dangerous snakes on the plateau, and no troublesome insects except fleas. Upon the ascending slopes there are several coffee plantations, and the mulberry tree thrives. Good roads have been opened through the surrounding forests, and a railway across the peninsula passes about 35 m. from Koonoor.

NEISSE, a fortified town of Prussian Silesia, on the right bank of the southern Neisse at its confluence with the Biela, 80 m. S. W. from Oppeln; pop. 17,000. The fortress, one of the most important in Prussia, was built by Frederic II. The town is clean and well built, and contains several manufactories of linens and woollens, and a number of distilleries. Neisse was besieged 3 times in 1428 by the Hussites, and taken by Frederic II. in 1741, by the Austrians in 1758, and in 1807 by the French, who held it till 1808.

NELLORE, a province of British India, in the Madras presidency, bounded by Goontoor, Arcot, Cuddapah, and the bay of Bengal; area, 7,959 sq. m.; pop. 985,690. The crops chiefly grown are rice, dry grain, &c.; and saltpetre, salt, and tobacco are exported. The capital, Nellore, is on the bank of the river Pena, 18 m. from its mouth in the bay of Bengal, 100 m. N. from Madras; pop. 20,000.

NELSON. I. A central co. of Va., bordered S. E. by the James river and N. W. by the Blue Ridge, and drained by the Rockfish, Rock, and Tye rivers; area, 840 sq. m.; pop. in 1860, 12,756, of whom 6,142 were slaves. The surface is hilly and the soil fertile. The productions in 1860 were 353,432 bushels of Indian corn, 123,280 of wheat, 1,488,780 lbs. of tobacco, and 17,066 of wool. There were 87 grist mills, 15 saw mills, 6 tanneries, 4 wool carding mills, 4 distilleries, 21 churches, and 347 pupils attending public schools. A canal extending along the James river connects it with Richmond. The value of real estate in 1856 was \$2,709,861, showing an increase of 80 per cent. since 1850. Capital, Lovington. II. A central co. of Ky., drained by Rolling fork and Beech fork of Salt river; area estimated at 850 sq. m.; pop. in 1850, 14,789, of whom 5,180 were slaves. It has an undulating surface and a fertile soil, especially toward the N. The productions in 1850 were 1,070,066 bushels of Indian corn, 227,188 of oats, and 87,828 lbs. of wool. There were 45 grist mills, 6 saw mills, 5 tanneries, 2 newspaper offices, 13 churches, and 1 college. Capital, Bardstown.

NELSON, DAVID, M.D., an American clergyman, born near Jonesborough, Tenn., Sept. 24, 1793, died at Oakland, Ill., Oct. 17, 1844. He was educated at Washington college, Va., and studied medicine in Danville, Ky., and in the Philadelphia medical school. He had but just entered on the practice of medicine when he joined a Kentucky regiment as a surgeon in the war of 1812, and proceeded to Canada. On his return he was near dying in the wilderness of fatigue and hunger, but was found just in time to save his life by his friend and relation, Col. Allen, who afterward fell at the river Raisin. He now resumed the practice of medicine. He had made a profession of religion in early life, but had relapsed into open infidelity. He at length, however, returned to his first religious convictions, forsook a lucrative professional career to become a minister in the Presbyterian

church, and was licensed to preach in April, 1825. He preached for nearly 3 years in different parts of Tennessee, and was engaged, in connection with two other gentlemen, in the publication of a periodical called "The Calvinistic Magazine." In 1828 he succeeded his brother Samuel as pastor of the Presbyterian church in Danville, Ky. While resident in that place, Dr. Nelson was in the prime of his eccentric and extraordinary genius. There was something singularly striking, almost unique in his manner; his eloquence was fervid, powerful, and picturesque, and Dr. Breckinridge called him "one of the greatest preachers on earth." In 1830, being deeply impressed with the importance of increasing the means of education in the West, he removed to Missouri, and was chiefly instrumental in establishing a college in Marion co., 12 m. from Palmyra. Of this institution he became the first president. Its most distinctive feature was, that the students supported themselves by occupying a part of their time in manual labor. In 1836, owing to a disturbance arising out of the slavery question, Dr. Nelson, who was a warm emancipationist, removed to the neighborhood of Quincy, Ill., and established an institute for the education of young men, especially for the missionary life. This as well as the previous institution failed, partly from Dr. Nelson's acknowledged lack of business habits and qualifications. In the latter part of his life he was subject to attacks of epilepsy, which gradually impaired his faculties. Dr. Nelson published a work on "The Cause and Cure of Infidelity," which has passed through many editions, beside many contributions to the public journals of the day.

NELSON, HORATIO, Viscount Nelson of the Nile, a British admiral, born at Burnham Thorpe, Norfolk co., Sept. 29, 1758, killed in the battle of Trafalgar, Oct. 21, 1805. His father was rector of the parish of Burnham Thorpe, and the early life of the son was marked throughout by the indomitable energy and the adventurous and fearless spirit for which he afterward became distinguished. Although of a slender frame and delicate constitution, he left school at the age of 12, and entered as midshipman on board the *Raisonné*, 64, destined for the Falkland islands, and commanded by his uncle, Capt. Maurice Suckling. But this expedition having been given up, he went in a merchant ship to the West Indies, whence he returned with a great horror of the royal navy. In 1773, the *Racehorse* and the *Carcass* having been fitted up for a voyage of discovery to the north pole, under the command of Capt. Phipps, Nelson, although a boy, was appointed coxswain of the latter vessel. On returning he was placed on board the *Seahorse*, 20, which sailed for the East Indies in the squadron of Sir Edward Hughes. But the climate of India soon prostrated him, and in 18 months he was compelled to return to England with an enfeebled body and despondent spirits. Recov-

ering his health on the voyage home, he was appointed acting lieutenant to the Worcester, 64, and subsequently 2d lieutenant to the Lowestoffe, 82, having passed with credit an examination for a lieutenancy, April 8, 1777. The Lowestoffe was employed against the French and American privateers, who were harassing the British trade in the West Indies. On one occasion, an American ship having struck its colors, the 1st lieutenant, after a trial, deemed it too dangerous to attempt taking possession of the vessel, as the sea was running high. "Have I then no officer who can board this prize?" exclaimed the captain indignantly. Seeing the master about to volunteer, Nelson stopped him, leaped into the boat, saying: "It is my turn now; if I come back, it will be yours," and returned, having boarded the ship. He soon afterward became 1st lieutenant on board the Bristol flag ship; in Dec. 1778, was appointed commander of the Badger brig, and post-captain, June 11, 1779, when he was assigned to the Hinchinbrook, 28, in which he distinguished himself at the siege of Fort San Juan and took the island of St. Bartholomew. But the crew of the Hinchinbrook were decimated by the pestilence, and its commander, worn out by sickness and fatigue, was forced to return to England. Having been restored by the Bath waters, he was appointed to the Albemarle, 28, and in the winter of 1781-2 cruised in the North sea, where he gained considerable knowledge of the Danish coast and its soundings. On returning in April, 1782, he was ordered to Quebec, and thence sailed with a convoy to New York; he there joined the fleet under Sir William Hood, and with him went to the West Indies, where he remained till the peace of 1783. After his arrival in England he retired to St. Omer, but in the spring of 1784 took command of the Boreas, 28, ordered to the Leeward islands. As the Americans were attempting to establish an independent commerce with the West Indies, Nelson resolved to enforce the navigation act, and with that view seized 4 American vessels with freight at Nevis, carrying island colors. Although the ships were ultimately condemned in the admiralty court, his course caused him much trouble and brought him no credit either with the colony or home government. At Nevis, March 11, 1787, he was married to Frances Herbert Nisbet, widow of Dr. Nisbet, and daughter of Mr. Herbert, president of that island. On its return, the Boreas was kept 5 months at the Nore as a slop and receiving ship; and this and other indignities so exasperated Nelson, that he determined to resign his commission. This resolution was given up after his favorable reception at court; but he retired to the parsonage house at Burnham Thorpe. While there a writ was served on his wife on the part of the American captains, who laid their damages at £20,000. He indignantly wrote to the treasury that if he were not supported he would take refuge in France. "If sixpence would save me

from prosecution," said he, "I would not give it." The government returned a satisfactory answer, and he was not further troubled. When the war with France broke out he was appointed, Jan. 30, 1793, to the Agamemnon, 64, and joined the Mediterranean fleet commanded by Lord Hood. By him he was sent with despatches to Naples, where he made the acquaintance of Sir William and Lady Hamilton. Subsequently he commanded a small squadron sent to Corsica to coöperate with Paoli against the French, and took Bastia, May 19, 1794, after a siege of 7 weeks. The Agamemnon was then ordered to Calvi to assist Gen. Sir Charles Stuart in the siege of that place. Here Nelson lost an eye from sand and small gravel driven into it by a shot striking the ground near where he stood. His name was not mentioned in the "Gazette," however, and he keenly felt the neglect. Afterward serving under Admiral Hotham, who had succeeded Lord Hood, he distinguished himself in the engagement with the French fleet, which had come out from Toulon to give battle to the English, and boarded the *Ca Ira* and the *Censeur*, the only two ships taken. About this time he was made colonel of marines, and, hoisting a commodore's pennant, proceeded to the coast of Italy, blockaded Leghorn, and superintended the evacuation of Corsica. In sailing with a convoy to Gibraltar, he fell in with the Spanish fleet at the mouth of the straits, and on Feb. 18, 1797, joined, with the intelligence, Admiral Sir John Jervis, then commanding the Mediterranean squadron. By him he was appointed to the *Theseus*, 74, and participated in the battle of Cape St. Vincent, which took place on the morning of the 14th. In this battle Nelson disobeyed the admiral's orders to tack in succession, and, seconded by Trowbridge in the *Culloden* and *Collingwood* in the *Excellent*, bore down upon 7 of the enemy's fleet, attacked the *Santissima Trinidad*, 136, passed on to the *San Nicolas*, 84, which he carried by boarding, and led his men on to the *San Josef*, 112, lying alongside, and compelled it to surrender. For his conduct Nelson, who had been created rear admiral before the action was known in England, was knighted, and was made a companion of the order of the bath; and Admiral Jervis was created Earl St. Vincent. In April, 1797, he was sent to bring away the troops from Porto Ferrajo, and shortly after commanded the inner squadron in the blockade of Cadiz. On July 14 he was sent to attack Santa Cruz, Teneriffe, and carried the place, but, not being able to capture the citadel, was forced to retire. In the attack his right arm was shattered by a grape shot. Immediate amputation became necessary, and for the cure of the wound he was obliged to return to England. There numerous honors awaited him. Congratulatory letters were addressed to him by the first lord of the admiralty and the duke of Clarence; the freedom of the cities of London and Bristol was conferred upon him; he was made a knight

of the bath, and received a pension of £1,000. In the memorial which he was called upon to present before receiving such a grant, he stated that he had been in 4 actions with the fleets of the enemy, in 8 actions with frigates, in 6 engagements against batteries, in 10 actions in boats employed in cutting out of harbors and destroying vessels, and in taking 8 towns; that he had also served on shore with the army 4 months, and commanded the batteries at the sieges of Bastia and Calvi; that he had assisted at the capture of 7 sail of the line, 6 frigates, 4 corvettes, and 11 privateers of different sizes; that he had taken and destroyed nearly 50 sail of merchant vessels, and had been engaged against the enemy upward of 120 times; in which service he had lost his right eye and arm, and had been severely wounded and bruised in his body. In April, 1798, hoisting his flag in the Vanguard, 74, he rejoined Earl St. Vincent at Gibraltar, and on May 9 sailed from that place with a small squadron to ascertain the design of the vast armament fitting out at Toulon. On the 23d he encountered in the gulf of Lyons a sudden storm by which his ship was dismasted, and in the fog that followed he missed the French fleet, which had sailed for Egypt with Bonaparte and his army on board. Having received a reinforcement of 10 ships of the line and one of 50 guns, he sailed for Alexandria; but not finding the enemy there, he returned to Italy to obtain supplies. Singularly enough, on the night of June 22, the French and English squadrons crossed each other's track without either being aware of the neighborhood of their enemy. Having obtained supplies at Syracuse, Nelson sailed again for Egypt, and on the morning of Aug. 1 descried the tricolor floating from the walls of Alexandria and the bay of Aboukir covered with ships. For many days previous he had felt despondent; now his spirits revived. "Before this time tomorrow," said he to his officers when leaving him to take command of their vessels, "I shall have gained a peerage or Westminster abbey." The battle began at 6½ P. M., and, with an interruption of 10 minutes, when the French flag ship *L'Orient* blew up, lasted till daybreak. (See *ABOUKIR*.) Nelson declared victory a too feeble word for the result of this battle, and called it a conquest. Had he been provided with small craft, he could have destroyed in a few hours the store ships and transports in the harbor of Alexandria; and so deeply did he feel the want of these, that in a despatch to the admiralty he declared: "Were I to die this moment, want of frigates would be engraven on my heart." During the engagement Nelson received a severe though not dangerous wound on the head from a langridge shot. The news of the battle of the Nile was received with boundless enthusiasm by the enemies of France, and congratulations and rewards without number were showered upon the victorious commander. He was created Baron Nelson of the Nile, with a pension of £2,000 to himself

and his two immediate successors; received magnificent presents from the grand seignior, the king of Sardinia, the king of Naples, the emperor of Russia, and the East India company; and the thanks of parliament and gold medals were voted to him and the captains engaged in the action. Seventeen days after the battle, Nelson sailed for Naples, and was received with great demonstrations of joy both by the populace and the court. Encouraged by his victory, the Neapolitan government broke openly with the directory, and sent an army under Gen. Mack against the French troops occupying the Papal States. But an incapable commander and cowardly soldiers were no match for the forces of France. The invading army was beaten back, Naples was entered in turn, the royal family compelled to flee, and the short-lived Parthenopean republic established. The king and queen and their suite were conveyed by Nelson to Palermo. The royalists, however, soon took the field under the lead of Cardinal Ruffo, and advanced upon the city of Naples. The garrisons of the Castello Nuovo and the Castello dell'Ovo, consisting of Neapolitan insurgents, capitulated to the cardinal, June 28, 1799, on condition that they should be allowed to march out with all the honors of war, and that the persons in the forts and all prisoners taken by the king's troops should be unmolested or conveyed to Toulon and there set at liberty. The part taken by Nelson in annulling this capitulation has been condemned as an ineffaceable blot upon his fame by Southey and nearly all his other biographers; but the publication by Sir Harris Nicolas of the "Nelson Despatches" places his conduct in a much more favorable light. On the 24th Nelson arrived in the bay, and immediately ordered the flag of truce to be pulled down, on the ground that the action of the cardinal in granting a capitulation was not only unauthorized but in direct opposition to the commands of the king, whose orders were explicit not to treat with the rebels. On the next day, no steps having yet been taken to carry the capitulation into effect, he addressed a note to the garrisons, stating that he would not permit them to embark or leave those places, and their surrender must be at discretion. On the 26th the insurgents submitted, with full knowledge that the cardinal's conditions had been annulled, and were detained as prisoners until the arrival of the king, July 10, when they were given up to the Neapolitan authorities. That Nelson was justifiable throughout in this transaction is now admitted; that he acted with strict regard to honor and good faith is apparent from his treatment of the garrison of Castellamare, who having surrendered before his arrival were permitted to go free, although the officer who received their capitulation had no authority to grant them terms. The hanging of Prince Caraccioli, the Neapolitan admiral who had joined the insurgents and served under the "Parthenopean republic," has also been

brought against Nelson as a crime. Caraccioli was accused of being a traitor, and having been captured and given up to Nelson was tried by a Neapolitan court martial, who condemned him to death, and submitted their sentence to Nelson as superior officer for confirmation. It has been charged that in these transactions the British admiral acted under the influence of Lady Hamilton, with whom his illicit connection had already commenced, but there is no proof that she had any thing to do with them. (See the "Nelson Despatches," appendix to vol. iii.) Although ordered by Lord Keith to sail with his whole force for the protection of Minorca, he continued in the bay of Naples, and succeeded in restoring the king to his dominions. For his services he received a sword splendidly enriched with diamonds, and was rewarded with the dukedom of Bronté, with a revenue of £3,000 a year. He soon after assisted Capt. Ball in the siege of Malta; but, mortified by the appointment of Lord Keith to the chief command in the Mediterranean, he returned to England through Germany in company with Sir William and Lady Hamilton, and landed at Yarmouth, Nov. 6, 1800, after an absence of 8 years. Honors of every kind awaited him; but in 3 months he was separated from his wife on account of his infatuated attachment to Lady Hamilton. His last words to her were: "I call God to witness that there is nothing in you or in your conduct that I wish otherwise." In Dec. 1800, a maritime alliance was formed between Russia, Prussia, Denmark, and Sweden in regard to the rights of neutral nations in war. For the purpose of breaking up this confederacy, a fleet of 52 sail was sent in March, 1801, to the Baltic under Sir Hyde Parker, Nelson consenting to act as second in command. The squadron passed the sound on the 30th, and entered the harbor of Copenhagen. To Nelson, at the head of 12 ships of the line and smaller vessels, making 36 in all, was assigned the attack; against him were opposed 18 vessels mounting 628 guns, moored in a line a mile in length, and flanked by two batteries. The action began about 10 A. M., April 2, and lasted 5 hours. About 1 o'clock Sir Hyde Parker made the signal for discontinuing. Nelson ordered it to be acknowledged, but, putting the glass to his blind eye, exclaimed: "I really don't see the signal. Keep mine for closer battle still flying. That's the way I answer such signals. Nail mine to the mast." By 2 o'clock, the Danish fleet being almost entirely taken or destroyed, he wrote to the crown prince the following note: "Vice-Admiral Lord Nelson has been commanded to spare Denmark when she no longer resists. The line of defence which covered her shores has struck to the British flag; but if the firing is continued on the part of Denmark, he must set on fire all the prizes he has taken, without having the power of saving the men who have so nobly defended them. The brave Danes are the brothers and

should never be the enemies of the English." An armistice of 14 weeks was agreed to, and in the mean time the accession of Alexander to the throne of Russia broke up the confederacy, and left matters on their old footing. For this battle, which Nelson said was the most terrible of all in which he had ever been engaged, he was raised to the rank of viscount. On July 24 he was made commander-in-chief, from Orfordness to Beachy Head, of the squadron for the defence of England; and on Aug. 16, 1801, he attacked the flotilla at Boulogne, but was forced to retreat with considerable loss. After the treaty of Amiens he retired with Sir William and Lady Hamilton to his seat at Merton in Surrey. But war breaking out again, he was appointed commander of the Mediterranean fleet, and set sail thither on May 20, 1803. He immediately blockaded Toulon, but in spite of his utmost vigilance a fleet escaped out of that port on Jan. 18, 1805, and shortly afterward joined the Cadiz squadron. Nelson followed in pursuit to the West Indies, and back again to Europe, but being unsuccessful he returned to England. Upon the receipt of the intelligence that the combined French and Spanish fleets were in Cadiz, he resumed his command of the Mediterranean fleet, and encountered the enemy off Cape Trafalgar, Oct. 21, 1805. The force under him consisted of 27 ships of the line and 4 frigates; the force opposed of 33 ships of the line and 7 frigates. On that day he wore his admiral's coat, bearing upon his left breast the insignia of the orders with which he had been invested. To all remonstrance against wearing so conspicuous a uniform he replied, referring to the insignia: "In honor I gained them, and in honor I will die with them." At 11.40 A. M., while bearing down on the enemy, he hoisted the signal: "England expects every man to do his duty," which was received with tremendous cheering by the whole fleet. At 10 minutes after noon the action began. In the heat of the battle, about 1½ P. M., he was struck in the shoulder by a musket ball. "They have done for me at last, Hardy," said he, as he was raised up from the deck; "my backbone is shot through." He was carried below, and the surgeon examining his wound pronounced it to be mortal. He continually expressed the greatest anxiety as to the result of the battle. At length Capt. Hardy came down from the deck, and congratulated his dying commander on having gained a complete victory. He did not know how many had struck, but 14 or 15 at least had surrendered. "That's well," answered Nelson, "but I had bargained for 20." Anxious that the vessels taken should be saved from the possible danger of a storm, he added in a stronger voice: "Anchor, Hardy, anchor. Do you make the signal;" an order which unfortunately was not obeyed, and in the gale that came up the following night all but 4 of the prizes were destroyed or lost. Next to his country, Lady Hamilton occupied his

thoughts. "Take care of my dear Lady Hamilton, Hardy; take care of poor Lady Hamilton." A few minutes before he died, he turned to the chaplain, and said: "Doctor; I have not been a great sinner. Remember that I leave Lady Hamilton and my daughter Horatia as a legacy to my country." He then frequently repeated: "Thank God, I have done my duty." These were the last words he uttered, and at 4½ P. M. he expired without a groan. The body was placed in a coffin made out of the mast of the *L'Orient*. This singular gift had been presented him by Capt. Hallowell, and before Nelson left London for the last time he had called at his upholsterer's, and told him to get it ready, for he should soon require it. He was buried in St. Paul's cathedral, Jan. 8, 1806, and his funeral, conducted at the public expense, was the most solemn and magnificent spectacle which had ever been witnessed in England. Honors were heaped upon his family. His brother, the Rev. William Nelson, D.D., was created Earl Nelson of Trafalgar and Merton, with an annual grant of £6,000, and permission to inherit the dukedom of Bronté; £10,000 were voted to each of his two sisters, beside £100,000 for the purchase of an estate. A few hours before his death he appended a codicil to his will, in which he left Lady Hamilton as a legacy to his king and country, and his "adopted daughter, Horatia Nelson Thompson," to the beneficence of his country. "These," continues the document, "are the only favors I ask of my king and country at this moment, when I am going to fight their battle." This codicil his brother concealed until the parliamentary grant to himself had been completed; and to it and his dying request in behalf of the same persons the British people paid no attention.—Nelson is the greatest name in the naval annals of England. "His whole life," says Alison, "was spent in the service of his country; his prejudices, and he had many, were all owing to the excess of patriotic feeling; he annihilated the French navy by fearlessly following up the new system of tactics, plunging headlong into the enemy's fleet, and doubling upon a part of their line, in the same manner as Napoleon practised in battles on land. The history of the world has seldom characters so illustrious to exhibit, and few achievements as momentous to commemorate. But it is to his public conduct and genius afloat that this transcendent praise is due; on shore, he appears in a less favorable light. Vain, undiscerning, impetuous, he was regardless of his domestic duties; an ardent lover, he was a faithless husband. He was perpetually liable to the delusion of art, and sometimes seduced by the fascination of wickedness. These weaknesses were owing to the ardent temperament of his mind; they arose from passions nearly allied to virtue, and to which heroic characters in all ages have, in a peculiar manner, been subject." As he left no legitimate children, his viscounty became extinct, but the barony devolved by lim-

itation upon his brother William, whose grand-nephew Horatio, Earl and Baron Nelson and Viscount Merton, is the present representative of the family. Horatia Nelson was the admiral's natural daughter, probably by Lady Hamilton; for it is a singular fact that while he was undoubtedly her father, her maternity is by no means so certain, and there are not wanting critics who maintain that the attachment between Nelson and Lady Hamilton was purely Platonic. Horatia was married to the Rev. Philip Ward, an English clergyman.—Among the biographies of Lord Nelson we may cite Clarke and MacArthur's "Life of Admiral Lord Nelson" (2 vols. 4to., 1809); Robert Southey's "Life of Nelson" (8vo., 1831); and Pettigrew's "Memoirs of the Life of Vice-Admiral Lord Viscount Nelson" (2 vols. 8vo., 1809). His letters to Lady Hamilton (2 vols. 8vo.) were published in 1814, and the "Letters and Despatches of Lord Nelson," edited by Sir Harris Nicolas (7 vols. 8vo.), in 1845-'6.

NELSON, ROBERT, an English theological writer, born in London, June 22, 1656, died there, Jan. 16, 1716. He was educated at Trinity college, Cambridge, and at an early age was elected a fellow of the royal society. Afterward he visited France and Italy in company with Halley. He enjoyed the friendship of some of the most eminent divines in the English church, particularly Bull, Tillotson, and Lloyd, but did not himself take orders. At the revolution he refused to take the oaths of allegiance and supremacy, but ultimately suffered his objections to be overcome by Dr. Keen, one of the deprived bishops. His most important works are: "A Companion for the Festivals and Fasts of the Church of England" (1704); "The Great Duty of Frequenting the Christian Sacrifice" (1707); "The Practice of True Devotion" (1708); and "The Whole Duty of a Christian" (1718).

NELSON, THOMAS, an American revolutionary statesman and soldier, born in York co., Va., Dec. 26, 1788, died there, Jan. 4, 1789. His father, William Nelson, for many years president of the colonial council, sent him in his 14th year to Cambridge, England, where, under the care of Dr. Porteus, he was educated at Trinity college. Such was the influence of the family in Virginia, that while he was on the voyage home he was elected a member of the house of burgesses, although he was then scarcely 21 years old. In his 24th year he married, and settled at Yorktown, where his family possessed great estates. Although leading the life of a man of leisure and culture, he became a decided partisan of the American cause in the controversy with the mother country, and rendered efficient service in that behalf in the house of burgesses. He supported the resolutions against the Boston port bill passed by the house in 1774; and upon the dissolution of the legislature by Lord Dunmore, he was one of the 89 members who entered into the association which, among other things,

recommended the appointment of delegates from the several colonies to meet in a general congress. He was a member of the first convention which met at Williamsburg in Aug. 1774. In 1775 he was again a member of the provincial convention, and in July he was appointed colonel of the 2d of the 3 Virginia regiments ordered to be raised, a position which he resigned upon being elected a delegate to the continental congress. He was a conspicuous member of the convention which met in Williamsburg in May, 1776, to frame a constitution for Virginia; and was selected to offer the resolution instructing the Virginia delegates in congress to propose a declaration of independence. Subsequently he signed the declaration of July 4, 1776. In May, 1777, he was obliged by an indisposition affecting his head to resign his seat in congress; but in the following August, during the alarm occasioned by the entry of the British fleet under Admiral Howe within the capes of Virginia, he was appointed commander-in-chief of the state forces; and soon after, in response to an appeal from congress, he raised a troop of cavalry with which he repaired to Philadelphia. The danger apprehended from Howe's expedition having been averted, his corps was disbanded, and he resumed his duties as a member of the legislature. In this body he strongly opposed the proposition to sequester British property, on the ground that it would be an unjust retaliation of public wrongs on private individuals. In Feb. 1779, he again took his seat in congress, but was obliged almost immediately afterward by a return of his former indisposition to resign. In May, however, he was suddenly called upon to organize the militia to repel a marauding expedition which was ravaging the Virginia coast. On this occasion he sent many of his own servants to work for poor persons who had been drafted into the hastily raised levies. Congress having called upon the states for contributions to provide for the French fleet and armament, the general assembly of Virginia resolved early in June, 1780, to borrow \$2,000,000 to be deposited in the continental treasury by the middle of the month. The public credit, however, was so low that there seemed little probability that the required sum could be raised. In this emergency Gen. Nelson came forward, and on his personal security succeeded in raising a considerable portion of the loan. About the same time he advanced money to pay two Virginia regiments ordered to the South, which had refused to march until their arrears were discharged. His ample fortune was now so seriously impaired, that he was involved in pecuniary embarrassments in the latter part of his life. In the spring of 1781 he redoubled his efforts to protect the state; and in addition to his military duties he was in June called upon to assume the functions of governor of the commonwealth, a position for which he was recommended by Jefferson, then retiring

from office. Being thus armed with executive and military power, he hastened with all the militia he could muster to oppose the enemy, who were ravaging the country; and with a prompt waiver of his official rank, he did not hesitate to cooperate, as second in command, with the continental troops under Lafayette. Prevented by the distracted condition of the country from consulting his council or applying to the legislature, and obliged to perform many acts on his own responsibility, he exercised dictatorial powers; and it was in no small degree owing to his exertions that the American army was kept together during its stay in Virginia. His extra-legal acts were subsequently fully approved by the Virginia legislature. He participated in the siege of Yorktown as commander of the Virginia militia, and again displayed his disinterested patriotism by directing that his own house, the largest and best in the place, and therefore in all probability the headquarters of Lord Cornwallis, should be bombarded, exclaiming to Gen. Lafayette: "Spare no particle of my property so long as it affords comfort or shelter to the enemies of my country." His services and those of the troops whom he had collected were highly commended in the general orders of the commander-in-chief, Oct. 20, 1781. The success of the American cause being now rendered sure, and his constitution being impaired by cares and fatigue, he resigned his office in Nov. 1781, and passed the rest of his life in retirement at his house in Yorktown or at a small farm in Hanover co., the remnants of his princely fortune, of which the greater part had been expended in the service of the country. He died so poor that his remaining possessions were sold at auction to pay his debts. His widow lived to be nearly 90 years of age, but neither she nor any of her descendants received any pecuniary recompense for the sacrifices made by her husband. Mr. Nelson's statue was one of the 6 selected to be placed around the Washington monument at Richmond, Va.

NELSON'S RIVER, of British North America, issues from the N. extremity of Lake Winnipeg, passes through a series of lakes, and falls into Hudson's bay, to the N. of Fort York, after a N. E. course of 800 m. It is the main channel of communication with the interior of the Hudson's Bay territory.

NEMEAN GAMES, one of the four great national festivals of the Greeks, so called from Nemea in Argolia, where they were held every 8d year. They were instituted by the seven against Thebes in commemoration of the death of the infant Opheltes, which had been destroyed by a dragon while Hypsipyle its attendant had gone to show the seven a well. On their return the seven slew the dragon and instituted funeral games. Other legends ascribe them to Hercules in honor of his destruction of the Nemean lion. It is probable, however, that these refer to a restoration of the

ancient festival, and its alteration to a celebration in honor of Jupiter. At first they were of a warlike character, only warriors and their sons participating, but they were afterward thrown open to all the Greeks. The exercises consisted of horse racing, running in armor in the stadium, wrestling, chariot racing, quoit throwing, boxing, throwing the spear, archery, and musical contests. The prize was at first a chaplet of olive branches, but afterward one of parsley. The management of these games belonged at different times to Cleonæ, Corinth, and Argos. Philip of Macedon was once honored by the Argives with the presidency of the Nemean games; and at their celebration in 196 B. C., Quintus Flaminius proclaimed the freedom of Argos.

NEMESIANUS, MARCUS AURELIUS OLYMPIUS, a Latin poet, who flourished in the latter part of the 8d century A. D. From the epithet Carthaginiensis commonly coupled with his name, it is inferred that he was a native of Africa. He was the author of poems on hunting, fishing, and aquatics, all of which have perished except a fragment of the *Cynegetica*, or poem on hunting, which extends to 825 hexameter lines, and is remarkable for the neatness and purity of its style. This remnant was first published at Venice in 1584; the best edition is that of Stern (Halle, 1832).

NEMESIS, in Grecian mythology, a daughter either of Erebus or of Oceanus. She was a personification of conscience, and is mentioned by Hesiod in connection with Shame. It was believed by the Greeks that the gods were enemies of excessive human happiness, and that there was a power which preserved a proper compensation in human affairs, from which it was impossible for the sinner to escape. This power was embodied in Nemesis, who was in a special manner the avenger of family crimes, and was particularly worshipped at Rhamnus, Patræ, and Ozycius. She was usually represented in works of art as a virgin, sometimes standing in a thoughtful attitude, holding in her left hand a bridle or branch of an ash tree, and in her right a wheel with a sword or scourge.

NEMESIUS, a Greek bishop of Emesa in Syria, who probably flourished about the beginning of the 5th century, and was the author of an extant treatise "On the Nature of Man." He was acquainted with all the physiological learning of his age, and his speculations touching the motions of the pulse and the uses of the bile have led some moderns to suppose that he was acquainted with the circulation of the blood and the functions of the liver. Like Plato he believed in the preëxistence of the human soul. The earliest separate edition of the work is that of Nicastus Ellebodus (Antwerp, 1565); the latest and best is that of O. F. Matthæus (Halle, 1802). There is an English translation by George Wither (London, 1636).

NENA SAHIB, the title of Dhundoo Punt, a Hindoo chieftain and a leader of the sepoy mu-

tiny in 1857, born in 1824 or 1825. He was the son of a Brahmin of the Deccan, and when he was a little more than a year old was brought to Bittoor, where Bajee Row, the peishwa or chief of the Mahrattas, adopted him in 1827. On the death of Bajee without heir of his body in 1851, an estate in the neighborhood which had been bestowed upon him during pleasure by the British was declared lapsed to the East India company, as they had previously refused to recognize inheritance of lands by adoption, and a pension of \$450,000 a year granted to him and his family in 1818 was also stopped. The Nena sent an agent to England to advocate his claims, but without success, and this supposed wrong he never forgave. He lived however in great apparent friendship with the English, imitating their customs as far as he could, and was permitted to occupy the town of Bittoor, where he possessed much wealth and influence. When the sepoy mutiny broke out in 1857, he was universally trusted by the English, who applied to him for a body of soldiers to guard the treasury at Cawnpore, which he immediately granted; but no sooner had the insurrection occurred at the latter place than he put himself at the head of the rebels (June 5), and killed all the Europeans that fell into his hands, among whom were two large parties, principally of women and children, who were endeavoring to escape down the Ganges from Futtehghurh. The English at Cawnpore in the mean time defended themselves until June 27, when they surrendered on the Nena promising to send them safe to Allahabad. They were permitted to embark, but immediately afterward fired upon, many being killed and the rest brought back to land. The men were put to death at once; the women and children, after surviving nameless outrages, were massacred July 15, the day before Havelock arrived at Cawnpore, and their bodies were thrown into a well. The Nena retreated to Bittoor, where Havelock defeated him on the 17th, driving him out of the town, and destroying his army. He soon collected another force, with which he followed Havelock into Oude, but afterward returned toward Cawnpore with the intention of attacking Gen. Neill, who was in garrison there with a small force. Reoccupying Bittoor, he threw out his left wing in the direction of Cawnpore, but it was driven back in confusion by Gen. Neill, Aug 15; and on the next day Havelock, who had returned from Oude, defeated his whole force in a sharp engagement. Owing to the exhaustion of the victors and their want of cavalry, the Nena escaped, and, without coming directly in contact with the British, except once more at Cawnpore, where Sir Colin Campbell defeated him, Dec. 6, continued an active and harassing warfare. On the occupation of Gwalior by the rebels in June, 1858, he was chosen peishwa of the Mahrattas, and his nephew Row Sahib was placed in command of the city. His subsequent career is difficult to be traced, for his energies

were bent rather upon escaping pursuit than conducting offensive operations. Long after the other leaders had submitted or been captured, he continued, with the begum of Oude and about 10,000 rebels, to infest the northern parts of central India and the frontiers of Nepal. A report that he died of fever in the latter part of 1859 was generally discredited, and it is uncertain whether he is alive or not. The last report concerning him (Aug. 1860) is that he had crossed the Himalaya in disguise into Thibet, and was encamped near the N. base of the mountains with about 10,000 men.

NENNIUS, an ancient British historian, supposed to have flourished in the early part of the 7th century. He was abbot of Bangor in Wales, and author of a history of the Britons from the arrival of Brutus the Trojan to A. D. 655. This work is entitled *Historia Britonum*, or *Eulogium Britannia*. The best edition of it is that of Stevenson (London, 1838). An English translation by the Rev. W. Gunn has been republished in Bohn's "Antiquarian Library" (London, 1848).

NEO-PLATONISTS. See ALEXANDRIAN SCHOOL.

NEOPTOLEMUS. I. The son of Achilles and Deidamia. He was originally called Pyrrhus from his red hair. When it was prophesied that Troy could not be taken without the aid of the son of Achilles, Ulysses and Diomedes were sent to bring him thither. He equalled his father in valor and cruelty, and at Troy was one of the warriors selected to be concealed in the wooden horse that was introduced into the devoted city. He slew Priam, sacrificed Polyxena on the tomb of Achilles, and dashed to the ground from the summit of a tower the infant Astyanax, the only son of Hector. Andromache, the widow of Hector, was assigned to Neoptolemus, and bore him several sons. Traditions differ concerning the subsequent events of his life, but most of them affirm that he settled in Epirus, and that he was murdered at Delphi, where he was buried and worshipped as a god. II. An officer of Alexander the Great, who first distinguished himself at the siege of Gaza in 332 B. C. On the division of the provinces, after the death of the conqueror, Armenia was assigned to Neoptolemus. When the Macedonian generals took up arms to contend for the empire of their master, he entered into correspondence with Antipater and Craterus, and refused to support the pretensions of Perdiccas; whereupon Eumenes, who had espoused the cause of the latter, defeated him and compelled him to flee from his province. With a small body of cavalry he repaired to the camp of Craterus, whom he persuaded to advance against Eumenes, by whose hand Neoptolemus fell in battle.

NEPAUL, an independent kingdom of Hindostan, bounded N. by the Himalaya mountains, which separate it from Thibet, E. by the British district of Darjeeling and the native state of Sikkim, S. by the British possessions,

and W. by Kumaon. It is included between lat. 26° 45' and 30° 45' N., and long. 80° 15' and 88° E.; length W. N. W. and E. S. E. 460 m., breadth 150 m.; pop. 1,940,000. The largest town is Catmandoo, the capital. Nepal is intersected by several large rivers, some of which have their sources on the table-land of Thibet, beyond the Himalaya, through which they force their way by narrow chasms of the most appalling depth. The most important streams are the Gogra and Gunga. The greater part of the kingdom belongs to the Himalaya region, only a tract about 20 m. in width lying within the plain which stretches southward from the base of the mountains. There are several summits of stupendous height, among which is Mt. Everest (29,002 feet), the highest known mountain in the world. From the N. boundary, which lies within the limit of perpetual snow, the elevations gradually sink into lower and lower hills, separated by fine valleys, among which is the great valley of Nepal, in which is situated the capital. It is about 9 m. wide, 13 m. long, and 4,000 feet above the sea. At the foot of these hills a belt of forest occurs, running E. and W. throughout the length of the country, and reaching within 10 m. of the S. frontier. It is succeeded by the Terræ (marsh) or Terreeana, a black, level, humid, malarious region, from 10 to 20 m. broad, skirting the frontier of the Bengal provinces and Oude, and covered with dense jungle. The geological formation of the hilly tract consists of limestone, hornstone, and conglomerate. Iron, lead, and copper are found; and gold and silver have also been said to exist, but it is thought that they are very scarce if not entirely wanting. The soil of the valleys is remarkably rich, and the climate and productions vary with the degrees of elevation. The bamboo, rattan, sugar cane, pineapple, and various tropical fruits alternate with the oak, pine, barley, millet, &c. Much land is cultivated in terraces, great attention being paid to its irrigation. Rice, maize, wheat, cotton, 3 kinds of pulse, and tobacco are grown. Rice is the staple food; several varieties of it are cultivated in cold and dry places, and even where snow falls. Various roots and herbs form a considerable part of the sustenance of the poorer inhabitants. The number of horned cattle is not great, but there are large flocks of sheep, some of great size with fine wool, from whose milk the Nepalese make cheese. Horses are brought from Thibet. There are elephants and tigers, though not numerous, black bears of great size, hogs, the hog deer, hares, foxes, and jackals. The woods are inhabited by great numbers of peculiar birds, and the rivers have abundance of fish. —The inhabitants consist of a variety of races, the dominant people being the Gorkhas, a tribe of Mongol origin, Hindoos in religion, who conquered the country about the close of the 18th century. They have enlisted in large numbers in the British E. I. army, and their services, particularly at the siege of Delhi, have caused

them to be regarded as valuable soldiers. They are faithful and courageous, though not very capable of endurance. (See GORKHAS.) Many Hindoos from Chitore settled in Nepaul at the time of the Mohammedan invasion, and some of them have preserved their blood pure to the present time, while others have intermarried with Chinese and Tartars. The Hindoos are found chiefly in the W.; the E. is populated by aboriginal tribes, among which are the Newars, Magars, Gurungs, Jariyas, Dhenwars, Bhootias, Mhanjees, and Bhanras. The Newars, who are the most important of these, are an industrious agricultural and commercial people, more advanced in the mechanical arts than the mountain tribes, ingenious and peaceable, excessively dirty, of middle size and great strength, with round flat faces, small eyes, broad noses, and open countenances. They are Buddhists to a certain extent, but have a priesthood of their own. Most of their arts appear to have been introduced from Thibet. The women are allowed to change their husbands as often as they please. Some coarse cotton cloth is made, and the natives work very well in iron, copper, and brass, and are good carpenters, though they never use the saw. The trade of the country is not of much importance, being injured by numerous government monopolies. A considerable quantity of timber is floated down the rivers, and finds a market principally at Calcutta. The government is strictly despotic; and the whole population are liable to military service in times of public danger, though not trained to arms. There is a standing army of about 85,000 men, armed and disciplined, in some measure, after the model of European troops. They are very brave, and have the reputation of being good soldiers.—Of the history of Nepaul little is known until the invasion of the Gorkhas (1768); it seems never to have been subject to the Moguls or any other great Asiatic conquerors. A war in which it became involved with Thibet in 1790 led to hostilities with the emperor of China, who, regarding himself as the protector of the lamas, sent an army of 70,000 men against the Nepaulese and extorted from them a nominal submission. A treaty of commerce was concluded with the British in 1792, and from 1802 to 1804 the latter had a political resident at the court of Catmandoo. In the mean time the country had been a prey to intestine feuds, during which it is remarkable that its boundaries were enlarged on all sides. In consequence of the repeated encroachments of the rajah upon the East India company's territories, the British made war in 1814, and invaded the country on the W. frontier, where their troops met with repeated losses, and their commander, Gen. Gillespie, was slain. In the following year, however, the campaign under Sir David Ochterlony was attended with very different results. The victory of Malowa, the capitulation of the famous Nepaulese commander Ameer Singh, and finally the rapid advance of the victors toward Cat-

mandoo, obliged the rajah to make peace, and a treaty was signed on terms very favorable to the British in March, 1816. The recent history of Nepaul has been given under JUNG BAHADOOR. Throughout the mutiny of 1857 the Nepaulese cultivated the friendship of the British, and a commission has in consequence been recently appointed by the latter to mark out a new boundary which will give to Nepaul a considerable addition of territory.

NEPENTHE (Gr. *νῆψ*, not, and *πένθος*, grief), a soothing drug known to the Egyptians, from whom, according to Homer, Helen learned the art of compounding it. According to Diodorus Siculus, the Theban women also possessed the secret of its preparation.

NEPHRITE. See JADE.

NEPOMUCEN, JOHN, or JOHN OF NEPOMUCK, the patron saint of Bohemia, born at Nepomuck in 1320, killed May 16, 1388. His true name was John Welfin. Having entered the church, he was made canon of Prague and confessor to the queen, and was offered higher dignities, which he modestly declined. King Wenceslas, suspecting his wife's fidelity, endeavored to force him to reveal her confessions, and on his refusal caused him to be drowned in the Moldau. He was canonized by Pope Benedict XIII. in 1729. He is greatly honored in Bohemia as a martyr, and invoked as a protector against slander.

NEPOS, CORNELIUS, a Roman author, probably a native of Verona or its vicinity, died in the reign of Augustus. Nearly all his works have perished. He wrote *Chronica*, an epitome of universal history; *Exemplorum Libri*, a collection of remarkable sayings and doings, like that of Valerius Maximus; *De Historicis*, and *De Viris Illustribus*. Two of the lives comprised in the last named work, those of Cato and Atticus, are extant. The well known *Excellentium Imperatorum Vita*, first printed at Venice in 1471, and long ascribed to Æmilius Probus, is now considered an abridgment by him of the work of C. Nepos. It has passed through numberless editions, and has been translated into most European languages.

NEPTUNE (*Neptunus*), the principal sea divinity of the Romans. The Latin poets identified him in all respects with the Poseidon of the Greeks. He was a son of Saturn and Rhea, and a brother of Jupiter, Pluto, Ceres, Vesta, and Juno. Like his brothers and sisters, he was swallowed by his father as soon as he was born, and thrown up again; or according to another account, his mother saved his life by hiding him among a flock of lambs, and offering to Saturn a young horse to which she feigned to have given birth. After Jupiter had overthrown his father, the empire of the sea fell by lot to Neptune. He is represented as being of equal dignity with his brother Jupiter, but of inferior power, though he sometimes threatened him, disputed the possession of Ægina with him, and once conspired against him. His palace was

in the sea near Eubœa, and he was the especial ruler of the Mediterranean. He assisted in building the walls of Troy, and, being refused the reward promised by Laomedon, ever after bore an implacable hatred to the Trojans, and in the war against Troy sided with the Greeks, often fighting with them, causing the earth to tremble, and encouraging them with the signs of his divine favor. He had power over the clouds and storms, over ships and mariners, and over all other sea divinities; and he held the earth in his watery embrace. For a long time he disputed the possession of Attica and Trœzene with Minerva, with Sol the sovereignty of Corinth, with Juno that of Argolia, with Bacchus that of Naxos; and at one time Delphi belonged to him. He was the creator of the horse, and the teacher of horsemanship. There were many legends about him; with Jupiter he fought against Saturn and the Titans; he crushed the centaurs under a mountain in Leucosia; and he sought the hand of Thetis; but refused it through fear when Themis foretold that the son of Thetis would be greater than his father. The wife of Neptune was Amphitrite, by whom he had three children, Triton, Rhode, and Benthesiomye, beside a large number of other children by divine and mortal women. He was worshipped in Argolia, in the Corinthian isthmus, and in Ionia, and had a temple in Rome, in the Campus Martius. The sacrifices offered to him were bulls, bears, rams, and bridled horses, and horse and chariot races were held in his honor. He had many surnames in allusion to his various attributes. In works of art his emblems are the trident, a spear with three points, the horse, and the dolphin; and he is portrayed sometimes in a state of calm, sometimes in agitation, corresponding to the different aspects of the sea over which he presides.

NEPTUNE, a planet. See LEVERRIER.

NERBUDDA, a river of Hindostan, which rises about lat. 22° 40' N., long. 81° 52' E., nearly 2,500 feet above the level of the sea, and after a course of 600 m., generally W., falls into the gulf of Cambay in lat. 21° 40' N., long. 73° 5' E. During the rains it rises in some places 70 feet and in others 20 above its level in the dry season. The Nerbudda has no tributaries worthy of notice. There are extensive forests on its banks; and in the district of Malwa its channel is worn to a great depth through columnar basalt. It is navigable for boats to Darea, 250 m. from its mouth, but the upper part of its course is obstructed by numerous rapids and falls.

NEREIDS, the name of the sea centipedes of the dorsibranchiate order of annelids, of which the genus *nereis* (Cuv.) is one of the best known forms. The class and ordinal characters are given under ANNELIDA. In the true nereids the tentacles are of even number; there is a single pair of maxillæ in the proboscis; the branchiæ are small plates in which a network of blood vessels is disposed; each of the nu-

merous feet has 2 tubercles, 2 bundles of bristles, and an under and an upper cirrus; the body is like that of a centipede, with many joints. They are active, crawling and swimming with facility; some live in crevices in rocks near the shore, in sponges, corals, deserted shells under stones, or wherever they can find a shelter; others burrow in mud or sand, occasionally making tubes or sheaths, from which they protrude the anterior part of the body, and into which they retreat quickly when alarmed; some of the tropical species are very large, and vividly phosphorescent at night. Their food consists of living and dead animal substances, such as marine worms and soft-bodied invertebrates. The species are numerous, and are found on almost all coasts.—The sea mice (*aphrodita*, Linn.) belong to the same order; the body is broad and flat, with 2 longitudinal rows of wide membranous scales covering the back and concealing the branchiæ. The common sea mouse (*A. aculeata*, Linn.) is 6 or 7 inches long and 2 broad, with the back covered with a flax-like substance in which are mixed spines and softer bristles, the latter shining with all the tints of the rainbow, and rivalling in beauty the lustre of the humming bird or the sparkling of the most brilliant gems.

NEREUS, in Greek and Roman mythology, a son of Oceanus and Terra, and the father of the Nereids. He is represented as the wise old man of the sea. His peculiar domain was the Mediterranean and Ægean. He was believed to have the power of prophesying, and of appearing to mortals in many shapes.—The Nereids, his daughters, 50 in number, were worshipped in Greek maritime towns, and on the isthmus of Corinth.

NERI, FILIPPO DE', commonly called in English St. PHILIP NERI, a saint of the Roman Catholic church, born in Florence in 1515, died in Rome in 1595. He belonged to a noble family of Florence. At the age of 19 he went to Rome, where he devoted himself to the care of the poor, was ordained priest, and founded a confraternity for the relief of destitute strangers, pilgrims, and other homeless persons. In 1564, in concert with Baronius, who afterward became cardinal, and a number of other pious friends, he established the congregation of priests of the oratory, for mutual improvement, study, preaching, and the instruction of youth, and became its first superior. The members of the congregation were not required to take vows, their founder saying that the spirit of charity should be their only bond of union. They were approved by Gregory XIII. in 1575, and soon spread over Italy and other countries. Filippo continued to govern them until 1592, when he resigned in favor of Baronius. St. Filippo de' Neri is supposed to have been the originator of the musical oratorio. He was canonized by Gregory XV. in 1622. His literary remains consist of his letters, a few poems, and *Ricordi*, or advice to youth. (See PRIESTS OF THE ORATORY.)

NERO, a Roman emperor, born at Antium on the coast of Latium, Dec. 15, A. D. 37, died by his own hand in 68. He was the son of Cneius Domitius Ahenobarbus, by Agrippina, the sister of Caligula, and his original name was Lucius Domitius Ahenobarbus. When he was 18 years of age his mother married her uncle the emperor Claudius, who 8 years afterward gave his daughter Octavia to Nero in marriage, and formally adopted him under the name of Nero Claudius Cæsar Drusus Germanicus. Under the care of the philosopher Seneca he is said to have made some progress in learning; for though he was weak, indolent, and self-indulgent, he possessed good natural talents, and in his 16th year delivered an oration in Greek in behalf of the inhabitants of Ilium and Rhodes. In 54 the murder of Claudius by Agrippina placed him on the imperial throne, his mother causing the emperor's death to be kept secret until he could be safely proclaimed by the soldiers. The senate and the provinces at once submitted, and no attempt was made to secure the purple for Claudius's own son Britannicus, who was 8 or 4 years Nero's junior. The first 5 years of the young emperor's reign, known as the *quinquennium Neronis*, were distinguished for clemency and justice, though his private life was from the first extremely licentious. The conduct of affairs was left principally to Seneca and Burrhus, under whose influence the happiest reforms were introduced into the state, and Nero daily rose in popularity; but the jealousy of Agrippina, who found herself shut out from power, soon overthrew the ascendancy of Seneca, though it did not establish her own. She threatened to disclose the circumstances of Claudius's death, and to incite the legions to support the claims of Britannicus; she abused Nero with contemptuous language, and upbraided him for his disgraceful amour with a low-born woman named Acte. Nero replied to these reproaches by causing Britannicus to be poisoned, and by plunging into still lower depths of immorality. In company with other dissolute young men he roamed through the city by night, beating and robbing passengers and breaking into houses. One of his boon companions was Otho, who was afterward for a few months emperor. Poppæa, the beautiful but profligate wife of this man, was at last the cause of Agrippina's death. Nero had become enamored of her, and sent Otho to Lusitania to get him out of the way; but Poppæa, who aspired to share the imperial throne, encountered in Agrippina an enemy who thwarted all her plans. Persuading the emperor that his mother entertained designs upon his life, she finally procured an order for her assassination (A. D. 59), and her death was communicated to the senate by Seneca, who was an accomplice in the crime. This was followed by the divorce of Octavia, who was soon afterward put to death, and the marriage of the emperor to Poppæa. In 62 Burrhus died, and Seneca

wisely asked leave to retire. Two years afterward a dreadful conflagration raged in Rome for 8 days, totally destroying 8 of the 14 districts of the city, and leaving only a few half-ruined houses in 7 of the others. Dion Cassius and Suetonius relate that Nero fired it himself, and it is said that, as he watched the progress of the flames from the top of a high tower, he amused himself with playing on the flute the drama of the destruction of Troy. The truth of the story is doubtful, but it was believed at the time, and Nero sought to transfer the odium of the conflagration to the Christians, many of whom he caused to be put to death. Some were covered with the skins of wild beasts and torn to pieces by dogs, and others were smeared with combustibles and burned by night in the imperial gardens, while the emperor drove his chariot by the light of the flames. The tyrant was liberal to the sufferers by the conflagration, and upon the ruins of the old city built a much finer one on a different plan, one of its most striking features being a vast palace for himself, which was called "the golden house;" but he defrayed the expense by robbery and extortion. The discovery of a conspiracy against him served to develop his ferocity. O. Calpurnius Piso, Plautius Lateranus, the poet Lucan, and Seneca were put to death for complicity in it. The senate was induced to receive the intelligence of their fate as the news of a great victory, and the infamous Tigellinus, the emperor's principal instrument, was decreed triumphal honors. Having killed Poppæa by a kick when she was with child, Nero now proposed to marry Antonia, his sister by adoption, and on her refusal ordered her to be put to death. He then bestowed his hand upon Statilia Messalina, whose husband Vestinus he had assassinated for marrying Messalina after the emperor had cohabited with her. The jurist Longinus was exiled, and the most virtuous citizens, among whom were Thrasea Pætus and Barea Soranus, were put to death. In the midst of these executions, Nero's highest ambition seemed to be to excel in the games of the circus. He visited Greece to display his skill as a musician and charioteer, and the Olympic games were delayed two years (from 65 to 67) that he might be present at them. At the Isthmian games he ordered the death of a singer whose voice overpowered his own. He returned to Rome as a conqueror, entering the city through a breach in the wall, riding in the chariot of Augustus, with a musician by his side, and the 1,800 crowns which he had won at the games displayed as the trophies of his expedition. He had already appeared upon the stage in Rome and other cities of Italy, and chariot racing, music, and every frivolous amusement now engrossed his time. But in the meanwhile a formidable insurrection was preparing. It broke out in Gaul, under Julius Vindex, governor of Celtica, who raised an army and offered the purple to Galba, then governor of Hispania Tarraconensis. Galba ac-

cepted the flattering proposal, but the troops of Vindex were defeated before Vesontio (Besançon), and their general was killed. There is little doubt that Galba would have yielded, but in the meanwhile Nero, who had reluctantly left his extravagances in Naples to assume the consulship alone at the capital, was deserted by the prætorian guard, condemned to death by the senate, and forced to flee to the house of one of his creatures in the suburbs. Here, after spending in an agony of fear and irresolution the night and part of the next day, he committed suicide, and died in the presence of the soldiers who had come to seize him. His corpse received an honorable burial from his concubine Acte and two of his nurses.—The military events of Nero's reign were upon the whole glorious to the Roman arms. In Armenia, which had been occupied by the Parthians, a war commenced in 58, and was terminated in 60 by Domitius Corbulo, who destroyed Artaxata, the capital, and captured the city of Tigranocerta, thus rendering the Romans masters of the whole country. Tiridates, the king who had been set up there by the Parthians, subsequently renewed the struggle, and after temporary successes was compelled to submit and go in person to Rome to do homage for his kingdom. Nero, however, soon afterward condemned Corbulo to death, a sentence which the old soldier anticipated by suicide. In 61 a great rising in Britain under Boadicea was put down by Suetonius Paulinus. A revolt also broke out in Judæa, and Vespasian was sent to suppress it; but the history of this war, which terminated with the conquest of Jerusalem by Titus, belongs rather to subsequent reigns.

NERO GERMANIUS, TIBERIUS CLAUDIUS DRUSUS. See CLAUDIUS I.

NERTCHINSK, the capital of a circle of its own name in Eastern Siberia, about 550 m. E. by N. from Irkutsk; pop. of the circle about 120,000, and of the town 6,000. The military post of Nertchinsk commands the frontier of China. The circle of Nertchinsk is generally mountainous, but the town is situated on low ground, and is often subjected to inundation. Its general appearance is unattractive, and most of the houses are built of wood. It contains several churches and schools, and derives great advantages from its extensive fur trade.—The celebrated Nertchinsk government mines are situated upward of 100 m. from the town, in the Nertchinskoi mountains. More than 4,000 persons were in former years employed in the silver mines alone. The total number of the convicts sentenced to labor in the mines of the empire in 1856 was 1,574, a portion of whom are employed in working the gold mines at Nertchinsk, where their condition is said to be deplorable and attended with the greatest

sufferings. The working of the lead and silver mines was stopped in 1848; the ore at Nertchinsk as well as in other parts of Siberia contained, according to official investigation, 9.7 oz. of silver and about 168 lbs. of lead to the ton. There are also mines of tin, cinnabar, and zinc in the circle of Nertchinsk, but they are not much worked on account of their remote situation and indifferent character. This circle is almost the only one of Russian Asia in which new discoveries of gold have been made since 1846, chiefly among the affluents of the river Shilka; and the produce rapidly increased from that time until 1850, but has since been decreasing. The gold extracted in 1856 amounted to 2,878 lbs. 6 oz. 6 dwt., and the silver to 1,856 lbs. 11 oz. The report of 1857 mentions no yield of gold at all, and only 7 lbs. 7 oz. 5 dwt. of silver. The yield of auriferous sands is said to be diminishing, and the old deposits are exhausted, while the spirit of mining enterprise has to some extent subsided. A small village (Nertchinskoi Zavod) has sprung up in the mining district, which contains about 300 houses for the use of the mining population. Several naphtha baths exist in the circle similar to those in Taurida.—Middendorff, of the Russian academy, on his tour of exploration in 1845, crossed the Chinese frontier and discovered that the Russian government erroneously regarded the Stanovoi mountains as their boundary toward China, the Chinese themselves having erected boundary posts in a much more southerly direction, and among the left affluents of the Amoor, and that thus a great extent of territory would accrue to Russia beside the outlet into the Pacific. Capt. Achte was subsequently employed in acting upon this discovery of Middendorff, which eventually resulted in the acquisition by Russia of the whole left bank of the Amoor.

NERVA, MARCUS COCCÆIUS, the 18th Roman emperor, born probably in Narnia, Umbria, A. D. 32, died in Rome, Jan. 27, 98. He was twice consul before his accession to the purple, in 71 with Vespasian, and in 90 with Domitian. On the assassination of Domitian, in Sept. 96, Nerva was proclaimed emperor by the people and soldiers. He discontinued Domitian's prosecutions for treason, discountenanced informers, permitted exiles to return, purchased land and distributed it among the poor plebeians, and made occasional donations of money and corn. By suppressing many of the public shows and festivals, and diminishing the expense of such as were tolerated, he economized the revenue, and increased the resources of his empire. In the second year of his reign a conspiracy was formed against him, at the head of which was a descendant of the triumvir Crassus. Its existence was however discovered in time; but Nerva having sworn, when accepting office, that no senator should suffer death under his rule, the leader was only banished to Tarentum and the inferior conspirators were pardoned.

NERVAL, GÉRARD DE. See GÉRARD DE NERVAL.

NERVII, an ancient people, who were regarded as the most savage of the tribes of Gallia Belgica. They had their capital at Bagacum (Bavai), and their territory bordered on the possessions of the Atrebatæ, Veromandui, and Ambiani. It was consequently included in what was afterward the diocese of Cambrai, Cambrai or Camaracum being one of their towns. They claimed a Germanic origin, but there is no evidence to determine whether they were Germans or not. Their country was defended against cavalry by an almost impenetrable quickset hedge, which Cæsar says a man could not see through. They joined the Belgian confederacy against the Romans, and under Boduognatus fought a great battle with Cæsar on the banks of the Sabis or Sambre (57 B. C.), in which their name and nation were nearly destroyed. Their chief men were reduced from 600 to 3, and their army from 60,000 to 500. Nevertheless, in 54 B. C. they joined with the Eburones in an attack on the camp of Q. Cicero, who had his winter quarters in their territory, and in the following year were again defeated by the Romans and forced to come to terms.

NERVOUS SYSTEM. The most important and remarkable characteristic that distinguishes the physical organization of animals from that of plants, is the existence in the former of a peculiar tissue or substance called nerve. The special endowment of this substance is what is termed sensibility, or that faculty by which an animal is capable of receiving impressions from external objects, and by which consequently it is brought into relation with the surrounding world. In most animals this tissue is so disposed as to form a distinct and complete apparatus called the nervous system. The development of this system is always in direct relation to the complexity of the physical organization and the degree of physical endowment. In the lowest forms of animal creation the existence of nervous matter is as yet undemonstrated, but it is presumed by some physiologists that it exists in the form of molecular matter diffused through the body of the animal. The tissue out of which the nervous system is constructed presents two varieties, described by anatomists as the white or fibrous matter, and the gray, cineritious, or vesicular matter. The white matter is developed in the form of fibres or filaments, bound together in fasciculi or bundles, which constitute what are called nerves; their function is internuncial or conducting. The gray matter is accumulated in masses called centres or ganglia; their office is dynamic, originating the so called nervous force. (For a more particular description of the microscopical anatomy and chemical analysis of nerve tissue, see BRAIN.)—Examining the nervous system in its comparative development in the animal creation, we find four principal types exhibited in the four great classes

radiata, mollusca, articulata, and vertebrata. We will briefly examine these in succession.

1. *Nervous System of Radiata*. In this class we find the simplest form of nervous system, and one which corresponds with the simplicity of the physical organization, the animal being formed by a series of similar parts. Thus in the *asterias* or 5-rayed star fish we have a chain of 5 ganglia surrounding the central mass, or body which contains the mouth and digestive cavity. These ganglia are united to each other by nervous arcs called commissures, and each sends into the ray or limb opposite to which it is placed nervous prolongations. 2. *Nervous System of Mollusca*. In these animals we have several separate and distinct organs, such as a digestive apparatus, a liver, gills, ovaries and testicles, the male and female function coexisting in the same animal; we have beside a muscular mantle and a foot or organ of locomotion. The necessities of this physical organization are met by a corresponding arrangement of the nervous system. Thus in *aplysia* there is an anterior or cerebral ganglion resulting from the junction of two above the oesophagus; this ganglion represents the brain, and is doubtless connected with whatever sensitive or volitional endowment the animal possesses. From this small nerves pass to form the pharyngeal ganglion, which supplies innervation to the digestive apparatus; from this two nerves pass backward to form the pedal ganglion, which also gives nerves to supply the mantle; and in the posterior part of the body there is an additional ganglion, called the branchial, the nerves of which are distributed to the gills. 3. *Nervous System of Articulata*. In this class we observe that the body is divided into a certain number of similar segments, of which the anterior, called the head, presents the greatest development. The nervous system in this class corresponds to their anatomical structure. Thus in the common centipede or *scolopendra*, the nervous system consists in two nervous cords running along the ventral surface of the animal, and presenting opposite to each articulation ganglionic enlargements; these ganglia send off lateral prolongations, which unite with each other on the upper surface of the body, forming a series of circular commissures. At the head there is a ganglion at the point of junction of the lateral prolongations from the infra-oesophageal ganglia, called the supra-oesophageal ganglion, and from this ring or collar arise the optic nerves and the other nerves that are distributed about the head. In insects we find a somewhat more complicated arrangement of the same type of nervous system, and one which presents very important analogies to the nervous system of the vertebrata. It consists in a ganglionic nervous cord, but the ganglia are arranged so as to correspond with the anatomical division of the animal into three distinct cavities, the head, chest, and abdomen. In the head we have the ganglia presiding over the functions of special

sense, prehension, and mastication; in the chest those that control respiration and the locomotive organs, the legs and wings; and in the abdomen those that are connected with the digestive and reproductive functions. 4. *Nervous System of Vertebrata*. The nervous system, as we find it developed in the mammalia, the last and highest class of the vertebrata, consists of an axis of nerve matter, called the cerebro-spinal axis, which is enclosed in the cavities of the cranium and spinal canal. This axis is constituted of ganglia and of longitudinal and transverse commissures, and gives off nerves which are distributed to the organs of sense, sensation, and motion. This cerebro-spinal axis, however, with its centres, commissures, and nerves, forms but one portion of the nervous system in the vertebrata, that which presides over the purely animal functions of locomotion, respiration, sensation, and intelligence. A separate and distinct system, called the ganglionic or sympathetic, controls the functions of organic or vegetative life; its centres are located in the visceral cavities of the body; they are connected with each other by longitudinal and transverse commissures, and send filaments to all the viscera. The cerebro-spinal axis, as it is developed in man, may be briefly described as follows. The principal ganglion is placed at the superior extremity of the axis, and is called the brain or encephalon. This is enclosed in the cavity of the cranium, and is enveloped by three membranes, the dura mater, the arachnoid, and pia mater. The encephalon is constituted of a series of ganglia connected with each other, and designated, counting from before backward, as: 1, the olfactory ganglia; 2, the cerebrum or hemispheres; 3, the corpora striata; 4, the optic thalami; 5, the tubercula quadrigemina; 6, the cerebellum; 7, the ganglion of the tuber annulare; and 8, the ganglion of the medulla oblongata. The cerebrum and the cerebellum present a convoluted surface; the others are smooth and irregularly rounded. The superior aspect of the brain presents a deep longitudinal fissure, which divides the cerebrum into two lateral halves, called the cerebral hemispheres; these hemispheres, however, are united at their base by a long commissure, designated as the corpus callosum. Upon its inferior surface each hemisphere is seen to be divided into an anterior, middle, and posterior lobe. The remainder of the axis, called the spinal cord, is a cylinder of nerve matter, extending through the entire length of the vertebral canal, where it is enveloped by prolongation of the membranes of the brain. Upon the anterior and posterior aspects of this cord are two longitudinal fissures, which indicate the two lateral halves of which this organ is composed. From the brain and spinal cord there arise 44 pairs of nerves, perfectly symmetrical in their courses and distribution. These nerves are distinguished as cranial and spinal. The cranial nerves, of which there are 12 pairs, are distributed mainly to

the organs of sense, and those of voice and speech; they emerge from the skull by the several openings at its base. The spinal nerves, of which there are 32 pairs, arise from the cord by two roots, one from the anterior, and the other from the posterior columns of the cord. They escape from the canal through the intervertebral openings, and are distributed principally to the voluntary muscles and the integuments of the neck, body, and extremities. The cerebro-spinal axis, or the nervous system of animal life, as it is called in contradistinction to the sympathetic system, or that of organic life, presents certain peculiarities in the several classes of vertebrata which deserve to be briefly mentioned. As we descend in the series of vertebrate animals, we are struck with the difference in the relative size and development of the brain and spinal marrow. The annexed table will show the proportion which the one bears to the other in weight in the four classes:

Class.	Species.	Proportion of brain to spinal marrow.	
Pisces.....	Lamprey.....	100	: 750
Reptilia.....	Triton.....	100	: 180
Aves.....	Pigeon.....	100	: 80
Mammalia.....	Mouse.....	100	: 23

The following table shows the relative proportions of the body and brain in the same classes:

Class.	Species.	Proportion of brain to body.	
Pisces.....	Lamprey.....	100	: 142,500
Reptilia.....	Turtle.....	100	: 454,500
Aves.....	Pigeon.....	100	: 9,100
Mammalia.....	Mouse.....	100	: 8,500

This diminution in the size of the brain in the lower vertebrata is observed chiefly in the cerebral hemispheres, the centres of instinct and intelligence. A few words will describe some of the more important anatomical differences in the cerebro-spinal axes of the three lower classes of vertebrata. The brain of birds presents a perfectly smooth surface, and is composed of 6 masses, viz., beginning anteriorly, the two lateral hemispheres, the optic tubercles, the cerebellum, and the medulla oblongata. The cerebellum is compressed laterally and convoluted transversely. The brain of birds has in common with reptiles and fishes certain peculiarities never observed in the brain of mammalia. They are: 1, the absence of the corpus callosum or broad commissure of the cerebral hemispheres; 2, the separation of the optic tubercles with the hemispheres; and 3, the existence of two ventricles in the optic tubercles. In reptiles, as in birds, the brain is without convolutions. The optic tubercles, however, instead of being smaller, are larger than the cerebral hemispheres, and placed as usual behind them. The cerebellum is behind the optic tubercles, and is generally small. The olfactory nerves are apparently continuous with the anterior or cerebral gan-

glia. The brain of fishes is composed of lobes placed one behind the other so as to form a sort of knotted cord. The optic tubercles, called also *tubercula quadrigemina*, and the cerebellum, are placed behind the cerebral ganglia, and are larger in proportion to the latter than in reptiles. The spinal cord differs essentially in the different classes of vertebrata only in the number of pairs of nerves which arise from it, this number being always proportioned to that of the vertebrae.—*Functions of the several parts of the Nervous System.* The first question that meets us in this inquiry is: What are the vital endowments of nerves and nervous centres? When we expose and irritate a nerve by chemical, mechanical, or electrical stimulus, we observe no visible change in the nerve itself, but we produce indications of pain and contraction of the muscles to which the nerve is distributed. We infer therefore from the effects of the irritation that it has produced some change in the nerve, or excited in it some vital endowment. This change has been compared to that wrought in a piece of malleable iron by the galvanic current; and the analogy has suggested the term polarity or polar force, as applicable to the condition produced in nerves by the application of stimuli. This property of nerves, by which they respond to external irritation, producing pain or muscular contraction, is called irritability; and one of its most remarkable characteristics is the instantaneousness with which the effect follows the irritation. This irritability or nervous force, as it is also called, can be excited at the centres and extremities as well as in the course of the nerves. The effects of irritation vary considerably, however, in different parts of the nervous system; thus there are certain ganglia, as for example the cerebral hemispheres, which may be irritated without exciting pain or muscular contraction. Considerable portions of these hemispheres are sometimes removed by accident or operation without producing any appreciable effect; the reason of this is, that these ganglia have no direct connection with the muscular system, and are not sensitive. There are other ganglia and nerves, moreover, the irritation of which produces effects that are entirely peculiar to themselves. Thus, irritation of the optic tubercles or nerves causes the sensation of light, irritation of the auditory nerve gives rise to the sensation of sound, and irritation of the olfactory and gustatory nerves to those of smell and taste. This difference in the effects produced by the irritation of different nerves is the basis of a division of the nerves into: 1, motor nerves, or those in which irritation produces muscular contraction; 2, sensitive nerves, or nerves of common sensation, in which irritation is followed by an agreeable or painful feeling, according to the nature or degree of the stimulation; and 3, nerves of special sense, in which irritation excites the peculiar sensations of light, sound, taste, &c. Many sensitive nerves arise from

nervous centres in such close proximity to motor nerves, that a stimulus applied to the former will react upon the latter, and produce not only a direct sensation, but what is technically called a reflex action. This property of reflection was supposed by Marshall Hall to reside in special nerves which possessed both an incident and a reflected fibre, or, as they are called, an afferent sensitive nerve leading to the centre, and an efferent motor nerve coming from the centre; these nerves he styled excitomotory. Probably the majority of all the nerves in the body are compound in their constitution; i. e., they are formed of sensitive and motor filaments combined in the same sheath, or fibrous covering, called the neurolemma. There is no appreciable difference in the structure of sensitive and motor nerves. The difference in their endowments can only be ascribed, in the present state of our knowledge, to the different nature of their central or peripheral connections. It is a remarkable fact that whatever part of a sensitive nerve be irritated, whether it be the centre, the middle, or the extremity, the same sensation will be produced. There are many familiar illustrations of this fact. For years after the amputation of limbs, patients will experience the sensation of fingers and toes; and when the trunk of a nerve is irritated, they will complain of pains or tingling in the extremities. The same law applies to nerves of special sense. Ordinarily their peculiar irritability is excited by stimuli applied to the periphery or ultimate distribution of the fibres; but occasionally, in consequence of disease, we have these special sensations caused by stimulation applied at the centre or origin of the nerves. Thus, the circulation in the brain of a diseased blood, or the existence of tumors or other local disease in the neighborhood of the centres of the nerves of special sense, gives rise to optical illusions, singular noises, disagreeable odors, &c. The stimuli that excite the nervous force or irritability are of two kinds, physical and mental. Physical stimuli embrace all external excitants of whatever nature—light, heat, sound, odor, and every variety of chemical, mechanical, and galvanic irritant. Mental stimuli result from the exercise of the will and thought. In all voluntary movements the mind is the direct stimulus of the motor nerve; and in certain deranged states of the nervous system, as in hysteria, the mind also seems to affect directly the nerves of sensation so as to excite pain. Motor nerves are never directly excited by physical stimuli. The latter act always on motor nerves through the medium of sensitive nerves, and, as before stated, the actions so produced are termed reflex actions. The most remarkable of the physical stimuli, and the one most analogous in its effects to the stimulus of the will, is galvanism. The effect of this stimulus is muscular contraction, and there are certain peculiarities in its mode of action worthy of mention. 1. If the current is made

to cross a nerve at right angles to it, no effect is produced; but if it be made to pass along the fibre, for the smallest fraction of an inch, it will excite more or less violent contraction of the muscles to which the nerve is distributed. 2. These contractions occur at the moment of making and breaking the current, and not while it is passing. 3. When the current is made to pass from the centre toward the periphery, it is called the direct current; when from the periphery toward the centre, the inverse current; and it is observed that contractions occur at the moment of making the direct current, and at that of breaking the reverse. 4. Continuance of the direct current exhausts the power of the nerve, but the reversal of the current will restore it; hence the value of the interrupted current, obtained from the electro-magnetic machines, as a remedial agent.—*Nature of Nervous Force.* We can judge of the nature of the nervous force only by its effects. The muscular contraction caused by the irritation of a nerve is due to the development of a peculiar vital force in the nerve structure, which is unlike any of the known physical forces. It bears certain analogies to electricity, and by some authors has been supposed to be identical with it. The reasons for this supposition are: 1, the identity of their effects on muscular fibre; 2, the rapidity of their action without producing any appreciable effect on the parts between the point of irritation and the point affected; 3, the extreme sensibility of nerve to the electric current; and 4, the phenomena of electrical fishes. None of these reasons are sufficient to establish the identity of the nervous and electrical forces, while the experiments of Longet, Matteucci, Prévost, Dumas, and others, showing that the most delicate tests can detect no galvanic current in the nerves, and that they are inferior to some other substances as conductors, prove conclusively that they are essentially distinct and different forces. With regard to the indisputable electrical phenomena that are observed in the torpedo and gymnotus, it is well ascertained that they depend on the existence in these animals of a special organ which generates electricity. The function of nerves, as has been remarked, is internuncial. They possess only limited capacity for the development of nervous force. Their office seems to be to conduct sensations from the periphery to the centre, and impulses from the centre to the periphery. Their connection with a centre is essential for the exercise of mental stimulus or the appreciation of external impressions. The determination of the sensitive or motor character of a nerve is effected by direct experiment on living animals, and by the effects of disease or injury of the nerves. The function of the roots of the spinal nerves, which supply the larger part of the body, was discovered in 1811 by Sir Charles Bell. He experimented on young rabbits by removing the posterior wall of the spinal column. "On laying bare,"

he says, "the roots of the spinal nerves, I found that I could cut across the posterior fasciculus of nerves, which took its origin from the posterior portion of the spinal marrow, without convulsing the muscles of the back; but that on touching the anterior fasciculus with the point of the knife, the muscles of the back were immediately convulsed." These experiments have been repeated by numerous observers, and the conclusion is established that the anterior root of each spinal nerve is motor and the posterior sensitive. (For a description of the functions of the encephalic nervous centres and the cranial nerves, see BRAIN.)—*Functions of the Spinal Cord.* The spinal cord consists of two anterior and two posterior columns made up of longitudinal nerve fibres. Each pair of columns encloses a crescentic mass of gray vesicular nerve matter. Some of the fibres originate from the gray matter within the cord, while others extend through the entire length of the cord and are connected with the brain. The discovery of the separate function of the roots of the spinal nerves was the first step in unravelling the important offices of the spinal cord. Experiments on living animals have established the following points in its physiology: 1. That the anterior and posterior columns of the cord correspond in their function to the anterior and posterior roots of the spinal nerves; for when the anterior column is divided, the power of voluntary motion is lost in the parts below the point of division, but sensation remains; and when the posterior column is divided, the anterior remaining intact, sensation is lost below the point of division, but voluntary motion remains perfect. 2. When the anterior and posterior columns are both divided, it is found that irritation of the portion of the anterior column attached to the brain produces no effect, while irritation of the lower segment causes convulsive action, showing that in the anterior column the nervous force travels from within outward and not from without inward. When, on the other hand, the portion of the posterior column attached to the brain is irritated, pain is produced, while irritation of the portion below the division causes no pain, showing that in the posterior column the nervous force travels from without inward and not from within outward. 3. The motor nerves derived from the right side of the body enter the right anterior column, and pass up the cord on the same side until they reach the medulla oblongata, where they cross over to the left side; the same course is followed by the motor nerves of the opposite side, which pass up the left anterior column till they reach the medulla, when they cross to the right side. This crossing of the motor nerves in the anterior columns of the medulla is termed decussation. The consequence of this arrangement is, that when any injury is inflicted on the right half of the anterior column below the medulla, the paralysis is on the same side; but when the injury is above the point at which

decussation commences, the paralysis will be on the opposite side. 4. Recent experiments by Dr. Brown-Séquard show that there is a crossed action in the sensitive as well as in the motor fibres of the cord. The decussation of the sensitive fibres, however, exists through the entire length of the posterior columns, and not in the medulla alone, as in the anterior columns. The effect of this is shown where one half of the posterior column of the spinal cord of a dog is divided; sensation remains on the corresponding side of the body, but is lost on the opposite side.—*Reflex Action of the Spinal Cord.* Thus far the spinal cord has been considered as a bundle of sensitive and motor nerves connecting the brain with the muscles and periphery of the body; but we find that the central portion of the cord contains a considerable amount of gray matter, and that it possesses in consequence the capacity of a nervous centre. When a frog has been decapitated, sensation and volition are of course destroyed, the communication between the body and the centres in which those powers reside being cut off; but it will be found, nevertheless, that irritation of either lower or upper extremity will be followed by contraction on the corresponding side; and when the irritation is excessive, contractions will occur in all the limbs. These phenomena, which are due to the action of the cord as a nervous centre, are not unfrequently observed as a consequence of disease or injury of the spinal cord. Whenever communication is cut off between any portion of the cord and the brain by disease, such as softening, or by fracture of the spine, sensation and the power of motion are lost in the parts below the point of disease or injury; but involuntary and uncontrollable contractions occur in response to any irritation applied to the surface, such as tickling of the soles of the feet, a draft of air, or the application of the galvanic current. For the production of these reflex phenomena it is necessary: 1, that the cord be in a state of integrity; and 2, that the continuity of the spinal nerves be unbroken. If the cord be broken up in the frog by the passage of a needle through the canal, irritation of the extremities will produce no effect; and if the sciatic nerve, for example, be divided, the cord remaining perfect, no contraction can be produced on the side of the division. It is inferred then from direct experiments and from the evidence furnished by disease that the spinal cord is a nervous centre, which supplies innervation to the muscular and cutaneous systems through the medium of sensitive and motor filaments; the sensitive filaments conveying impressions from the surface to the centre, and the motor filaments transmitting impulses from the centre to the surface.—*Sympathetic or Ganglionic System.* This system, which is sometimes called the nervous system of organic life, consists in a double chain of nervous ganglia occupying the visceral cavities of the body, and extending along the front

and sides of the vertebral column from its anterior to its posterior extremity. There are 4 symmetrical pairs of ganglia in the head, 8 pairs in the neck, 10 pairs in the chest, an irregular aggregation of ganglia in the abdomen called the semilunar ganglion, and 5 pairs in the pelvis. These ganglia are all connected with each other by transverse and longitudinal commissural fibres, and they send off some filaments to join nerves from the cerebro-spinal system, and others to be distributed to all the viscera which are concerned in the maintenance of organic or purely vegetative life. The state of knowledge concerning the special properties and functions of the sympathetic system of nerves is less advanced than that which relates to the cerebro-spinal system. The reasons for this imperfect knowledge are, the difficulties of experimenting on this system from the peculiarities of its situation, and the very complex connections of the sympathetic and cerebro-spinal systems.—For further information on this subject, reference may be made to the following works: Longet, *Anatomie et physiologie du système nerveux* (1842); Mayo "On the Nervous System" (1842); Carpenter's "Principles of Human Physiology" (1846; 5th ed., 1855); "Cyclopædia of Anatomy and Physiology," Todd and Bowman, "Physiological Anatomy and Physiology of Man" (1850); Dalton's "Treatise on Human Physiology" (New York, 1859).—**NERVOUS DISEASES** are properly divided into the functional and structural diseases of the nervous system. The functional diseases are those in which there is no morbid change or lesion in the nerve structures to account for the symptoms; they manifest themselves by irregular, depressed, or exalted conditions of the processes and peculiar functions of the nervous system, viz., sense, sensation, and motion. They may be enumerated as follows: 1. The numerous varieties of neuralgia which are independent of disease of the nerves or their centres. (See NEURALGIA.) 2. The various forms of insanity, as delirium, monomania, dementia, and general paralysis, where no morbid change occurs in the brain to account for the symptoms. 3. The protean nervous phenomena, neuralgia, paralysis of sensation and motion, convulsions, and the various exhibitions of mental and moral perversity, constituting the disease known as hysteria. 4. Delirium tremens, that derangement of the nervous functions, manifested by optical illusions, hallucinations, mania, and muscular trembling, which arises from exhaustion of the nervous power produced by prolonged stimulation by alcohol. 5. Chorea or St. Vitus's dance, an affection occurring generally in young girls between the period of dentition and puberty, and consisting in irregular contractions of the voluntary muscles. This disease has been graphically termed "insanity of the muscles." 6. The convulsions and paralyzes that occur in infancy and childhood from the irritation of teething or from gastric and intestinal derange-

ments. 7. Tetanus or locked-jaw, a rigid spasm of the voluntary muscles arising from an exalted state of the reflex function of the spinal cord, sometimes spontaneous, but more often the result of lacerated wounds. Hydrophobia may be included under this head, inasmuch as no traces of organic change are discoverable in the brain or spinal cord to account for its phenomena. 8. The rare and curious derangements known as catalepsy and ecstasy. (See CATAPLESY.)—Structural diseases of the nervous system, or those in which the nervous symptoms arise from some morbid change or lesion in the nerve structures, may be divided into: 1, diseases of the brain and spinal cord and their coverings or membranes; and 2, diseases of the nerves. The brain and spinal cord are subject to diseases affecting their membranes, their substance, and their blood vessels. The diseases of the membranes are principally inflammatory. The dura mater is not often inflamed except as a consequence of tertiary syphilis, and of injury, such as severe contusion or fracture of the skull. The arachnoid and pia mater are not unfrequently the seat of inflammation. This inflammation is termed arachnitis, meningitis of the brain or spinal cord, or in common language inflammation of the brain or brain fever. It occurs sometimes spontaneously, when it is termed primary; and sometimes as the result of previous or coexisting disease, such as typhus and typhoid fever and Bright's disease of the kidney, when it is called secondary. The inflammation of the membranes of the brain common among scrofulous children, called acute hydrocephalus or water on the brain, is secondary to the deposit in the pia mater of tubercles. The substance of the brain or spinal cord is sometimes, though rarely, the seat of inflammation that terminates in abscess. The substance of the brain and spinal cord occasionally undergoes changes in its consistence. Very rarely it becomes hardened, probably in consequence of chronic inflammation; frequently it becomes softened, a change technically called *ramollissement* or softening. Pathologists distinguish two kinds of softening, the red and the white; the red is regarded as the consequence of inflammation, and the white as the result of a defective nutrition arising either from an insufficient supply or a poor quality of the blood, or from disease of the vessels. The brain is also occasionally the seat of tumors; these are sometimes fibrous and grow from the membranes, sometimes they are made up of watery cysts which contain entozoa, and sometimes they are constituted of deposits of tubercular or cancerous matter. The blood vessels of the brain are also subject to diseased conditions. Sometimes the blood becomes stagnant in them and overloads them, causing what is called congestion of the brain; when this is sufficient to produce loss of consciousness, sensation, and motion, it constitutes simple apoplexy. Sometimes the blood vessels are

weakened through a fatty deposit in their walls, so that under the influence of unusual pressure they rupture and give exit to blood, which escapes of course into the substance of the brain; this constitutes what is termed cerebral hæmorrhage or apoplexy with extravasation. The consequences that follow hæmorrhage into the substance of the brain or spinal cord vary according to the location and extent of the hæmorrhage. It may prove instantaneously fatal, where the clot ruptures or presses upon the centres of the respiratory nerves, or it may cause paralysis of sense, sensation, and motion, more or less completely, through disintegration of the structure or pressure upon the centres that preside over these functions. The term hemiplegia is used to indicate the loss of sensation and motion in one lateral half of the body, and the term paraplegia to indicate the same paralysis in the lower half of the body.—Diseases of the nerves themselves are not numerous. (See NEURALGIA.) Epilepsy, which is sometimes a purely functional disease of the nervous system, and sometimes organic in its origin, is described under its own head.

NESHOBA, or NASHOBA, an E. co. of Miss., intersected by Pearl river and drained by its branches; area, 600 sq. m.; pop. in 1850, 4,728, of whom 1,885 were slaves. Much of the land is uncultivated. The productions in 1850 were 158,285 bushels of Indian corn, 55,696 of sweet potatoes, and 1,422 bales of cotton. There were 5 flour mills, 8 saw mills, 3 tanneries, 6 churches, and 109 pupils attending public schools. Capital, Philadelphia.

NESSELRODE, KARL ROBERT VON, count, a Russian diplomatist, born on board a Russian frigate in the port of Lisbon, Dec. 14, 1780, and baptized in the Protestant faith on board an English ship. He is descended from a noble German family, long settled in the provinces of the Lower Rhine, who were made at the beginning of the 18th century counts of the empire. A younger branch became also magnates of Hungary, and removed to Russia under the reign of the empress Anne. The grandfather of the present count was employed in the Russian diplomatic service, and his father, Count MAX (born 1724, died 1810), negotiated the marriage of Paul with the niece of Frederic the Great, and enjoyed the confidence of Catharine II., who employed him in many diplomatic missions. He married at an advanced age Mlle. Gontard of Frankfort-on-the-Main, who followed her husband in his embassy to Portugal, and on her journey thither gave birth to the present count, who received an excellent education, began his career in the military service, but early became attaché to the various embassies of his father. Subsequently he served in that capacity under M. Markoff in Paris; on the rupture between Russia and France after the execution of the duke d'Enghien, he was transferred to the legation at the Hague under Prince Dolgoruki; and on that ambassador's departure, he remained there as chargé d'affaires (1806-'6) until

the accession of Louis Bonaparte led to his withdrawal. He rejoined the embassy in Paris with the rank of councillor of legation in 1807, and succeeded in neutralizing the influence of his chief, Count Tolstoi, whose excessive hatred of the French made him unpopular at the court of Napoleon. Nesselrode, who had the manners of a man of the world and great tact as a diplomatist, gained the favor of the emperor Alexander, particularly by the brilliant style of his diplomatic compositions (which however were drawn up by his secretary, the son of Madame de Krüdener), and received an appointment in the ministry of foreign affairs in St. Petersburg. Although his family had been naturalized in Russia for several generations, they were unconnected with any of the high Russian families. Count Nesselrode married, however, the daughter of the finance minister, the future Count Gurieff; she was neither young nor attractive, but had been maid of honor to the empress dowager, and was moreover understood to possess considerable financial ability. At the height of her husband's career, the countess was in partnership with one of the first commercial firms of St. Petersburg, called the "Dutch house" or *maison Hollandaise*, which, sheltered by the illustrious partner, derived large profits from smuggling. As councillor of the cabinet he was frequently brought into personal contact with the emperor, who learned to appreciate his knowledge of international law and of European affairs. At the same time he knew how to disguise his superiority under an appearance of modesty, and to make the ideas which originated from his own mind appear to proceed from the emperor. The favorable impression which he thus produced, and the influence of the empress dowager and of his wife, led to his being intrusted with the ministry of foreign affairs *en second* after the rupture with Napoleon in 1812, although he was then only 32 years old. At first invested only with the title of secretary of state, he actually began from that time to control the relations of Russia with foreign countries. His immediate chief, Count Razumofski, together with Kutusoff, Wolkonski, and Balaschoff, were opposed to any coalition with England and Prussia after the campaign of 1812, but wished to stop after having overrun Poland. But Nesselrode, with all the Germans and the foreigners who surrounded Alexander, took the opposite view. The coalition was formed in Kalish in 1813, and Nesselrode's influence became all-powerful. The negotiations and treaties with England, Sweden, Prussia, and Austria, which determined the result of the conflict with France, were almost all concluded under his influence. In the night of March 31, 1814, he signed the capitulation of Paris, which put an end to the wars of the first French empire; and 42 years afterward he retired from public service after the signing of the treaty of peace in Paris, March 30, 1856, which terminated the war with Napo-

leon III. and his allies. At the congress of Vienna, Nesselrode, Metternich, and Talleyrand were the leading spirits; and Nesselrode was the first to assume for Russia that attitude of superiority which, combined with a tone of courteous and bland moderation in communicating with other nations, has since given to Russian statecraft a distinguished position in the diplomatic world. Sympathizing most with Austria, on account of her absolutist tendencies, he endeavored at the same time to maintain intimate relations with Prussia, and also showed great moderation toward France, effectually opposing at the congress of Aix la Chapelle Great Britain's desire of prolonging the occupation of France by foreign garrisons, and exerting himself to obtain a reduction of the enormous fines imposed upon her after the battle of Waterloo. Louis XVIII. and his minister Richelieu showed their gratitude to Nesselrode and his colleague Pozzo di Borgo, and immense amounts of money passed into the hands of both. The great wealth secured by him on that and other occasions, makes him now one of the richest men of Europe. He is one of the most extensive sheep graziers in Russia, his flocks amounting to upward of 150,000, and his personal property is said to be almost fabulous. Though respected on account of his great ability, the prosaic tenor of his mind was not congenial to the poetical and mystical disposition of Alexander, who regarded the holy alliance as a bond of religion, while Nesselrode looked upon it merely as a political power. While preserving the first place in the foreign ministry, he was to some extent supplanted for some time in the emperor's confidence by Count Capo d'Istria, who was appointed as his colleague, and who would probably have undermined his influence more permanently but for the outbreak of the Greek revolution, which led to his withdrawal and left Nesselrode sole master of the foreign office. The revolutionary movements which at the same period agitated Italy, Spain, and Portugal, caused Nesselrode and Metternich to adopt the most stringent policy, which had reached its climax of oppression at the time of the death of the emperor Alexander I. (Dec. 1, 1825). Nesselrode continued to enjoy the confidence of the new czar Nicholas, whose energy and commanding individuality, however, made Nesselrode's position less influential than it had been under his predecessor. Nesselrode's policy having always been marked by a tone of moderation and an excessive caution, the hostile attitude assumed toward Turkey soon after the accession of Nicholas was attributed rather to the emperor than to his minister; while the skill which the latter manifested in the whole course of negotiations, from those which preceded the battle of Navarino and the occupation of the Morea to the peace of Adrianople, contributed to strengthen the political influence of Russia. In 1844 he was promoted to the rank of chancellor of the empire. He

esteems so highly his title of count of the sacred empire that he repeatedly refused the title of prince offered to him by three successive czars; but his emoluments from his various offices were enormous. From that time Nesselrode's influence was constantly increasing. Pozzo di Borgo and his other rivals of the old school of diplomatists gradually disappeared from the public stage, and their successors, the Brunnows, Meyendorffs, Kisseleffs, Gortchakoffs, &c., served their apprenticeship in his chancellorate. Under him originated principally the fashion in Russian diplomacy of writing for the use of the czar brilliant and elaborate documents, and to this capacity of *rédiger les rapports*, as it is called, Matschewitch, Brunnow, Meyendorff, and other diplomatists are chiefly indebted for their success. Nesselrode's administration, distinguished for its unity of spirit and perfect mechanism, was only weakened by his inflexible adherence to the traditional policy of the holy alliance, but tempered by his desire of maintaining friendly relations with France and the other European powers. This peaceful disposition seems to have clashed with the impetuous and uncompromising character of Nicholas, particularly during the complications which led to the Crimean war; and although Nesselrode continued to conduct the foreign affairs during the lifetime of Nicholas and while the war was in progress, he was relieved from his duties July 30, 1856, 17 months after the emperor's death, and 4 months after the signing of the treaty of peace at Paris, since which time he has lived in retirement. Throughout his official career, Nesselrode was noted for kindness toward his subordinates, and for obtaining for them large pecuniary and other advantages. Conspicuous among his personal habits is his fondness for cookery and his skill in inventing new and famous dishes, as for instance the pudding *à la Nesselrode*, his daily consultations with his cooks having actually during his tenure of office preceded those with his employees. His wife died in Kissingen about 1846. His only son is employed in the foreign ministry of Russia, and is married to Countess Zakrewsky, whose intimacy with Alexandre Dumas, jr., gave rise to considerable comment. One of his daughters is married to Baron Seebach, the Saxon minister; another to Count Chrepowitch, for a time minister in Naples, Brussels, and England, but now retired from service; and his third daughter is unmarried.

NESTOR, a legendary Grecian hero, son of Nelus and Chloris, of Pylos. Previous to going to Troy he had taken part in wars with the Arcadians and Eleans, and in the conflict of the Lapithæ with the Centaurs; and he is also enumerated among the Calydonian hunters and the Argonauts. He went to Troy with 60 ships, and there figured as soldier, councillor, and orator, being appealed to in all dissensions among the Grecian commanders. In the famous quarrel between Agamemnon and Achilles, he effected

their reconciliation. He returned home in safety after the fall of Troy, and is said to have governed wisely three generations of men.

NESTOR, the earliest Russian chronicler, born about 1056, died about 1116. In the 29th year of his age he entered the Petcherskoi convent of Kiev, where he wrote his annals of Russia, commencing with the first appearance of the Varangians in that country, about the middle of the 9th century, and bringing the history of his nation down to his own times, various events of which he described from personal observation. He wrote in the old Slavic church dialect, and both as regards the language and the contents the original work has been considerably altered by the modifications and interpolations of various continuators, so that the real merits of Nestor can hardly be ascertained. The best edition of the work is that of Pogodin (St. Petersburg, 1841). The principal translation and critical illustration of the text are by Schlözer, *Nestors Russische Annalen*, &c. (5 vols., Göttingen, 1802-'9).

NESTORIANS, a sect of early Christians who derived their name and existence from Nestorius, bishop of Constantinople in the 5th century. He was a native of Syria, a disciple of Theodorus of Mopsuestia, and, before he became bishop, a presbyter of Antioch. He was distinguished for his zeal against the prevailing heresies of his time, particularly those of the Apollinarists, who taught that Christ had not a human soul, his divine nature supplying its place, and that consequently the two natures were mixed. In his opposition to this doctrine Nestorius went to the other extreme, and maintained that there was a great distinction between Christ as the Son of God and Christ as the son of man; that the actions and sensations of the one person were to be carefully discriminated from those of the other; and that the Virgin Mary could not be called *θεοτοκος*, "mother of God," but only *χριστοτοκος*, "mother of Christ," because it was only the human nature of Jesus Christ that was born of her, since God could neither be born nor die. His opinions were vigorously combated by St. Cyril, bishop of Alexandria, who by advice of Pope Celestine called a council at Alexandria in 430 to determine the controversy. By this assembly Nestorius was judged guilty of blasphemy and anathematized. He retorted by charging Cyril with confounding the two natures of Christ, and anathematized him in turn. The emperor Theodosius II. thereupon called a general council at Ephesus in 431, at which Cyril presided, and Nestorius, refusing to appear when summoned, was again condemned, deprived of his bishopric, and sent into banishment, where he passed the rest of his life. The council declared the true sense of the church to be that Christ consists of one divine person, yet of two natures, not mixed and confounded, although intimately united, forming what is known to theologians as the hypostatical union. But this definition did

not end the controversy. John, bishop of Antioch, and several other eastern prelates, held another council at Ephesus, and issued a severe sentence against Cyril; and though a reconciliation was effected between John and Cyril in 483, the disciples of Nestorius continued to propagate his doctrines throughout the East. They met with numerous adherents, particularly in Persia, where they found zealous auxiliaries in Barsumas, bishop of Nisibis, and Maanes, bishop of Ardashir. The Persian king expelled all the orthodox Christians, and made the chief cities of the monarchy, Seleucia and Otesiphon, the seats of a Nestorian patriarch. A famous Nestorian school was established at Nisibis, and before the close of the 6th century the heresy had spread over Chaldaea, Assyria, Syria, Egypt, and Arabia, and had penetrated to India, Tartary, and China. Their patriarch was nominally of Babylon, but his actual see was at various times Seleucia, Otesiphon, Bagdad, and Mosul. They were almost from the first divided among themselves, and at various synods adopted doctrines, such as the existence of two distinct persons in Christ as well as two distinct natures, which it is not agreed that Nestorius himself ever taught. A portion of them adhered to the Monophysite heresy. (See CHRISTIANS OF ST. THOMAS.) In 1551 a dispute arose among the Nestorians respecting the election of a patriarch, one party demanding Simeon Barmamas and another Sulaka or Siud. Sulaka, having submitted to the pope, went to Rome, was consecrated by Julius III. in 1553, taking the name of John, and returned to Chaldaea with a number of missionaries well acquainted with the language. The party of Nestorians whom he reconciled to the communion of the Roman see received an accession in 1555 in the person of Simeon Denha, archbishop of Jelu, who afterward succeeded to the patriarchate and removed his see to Ooroomiah in the mountainous part of Persia. All his successors up to the present time have borne the name of Simeon, and are called patriarchs of Babylon. These united Nestorians are commonly known as Chaldean Christians. They number perhaps 80,000, and are found principally on the western slope of the Koordish mountains. They do not acknowledge the name of Nestorians, calling themselves only Kaldani. Their patriarch is appointed by the pope, but they say mass in Chaldaic according to their ancient custom, and they have many practices which differ widely from those of western Christians. The non-united Nestorians recognize Nestorius as one of the fathers of their church, but not as its founder. They inhabit the W. part of Persia, and number about 70,000. They profess the Nicene creed with a few modifications, but assert the distinction of persons and natures in Christ; refuse the title of "Mother of God" to the Virgin Mary; disbelieve in purgatory, but pray for the dead; acknowledge 7 sacraments, though it seems uncertain which they are, burial being

sometimes reckoned as one; permit marriage to all the clergy except bishops and the patriarch (though this restriction was violated by the patriarch Mar Yohannan in 1859); and discard auricular confession, though it is prescribed in their ancient books. It is difficult in fact to ascertain precisely what they believe. "I was assured," says Col. Shiel, "by an American missionary to the Kaldani that their belief was in perfect accordance with that of the churches of Rome and England; while a Lazarist missionary to the Catholic Kaldani near Ooroomiah affirmed, with equal positiveness, that their disbelief in Christ's Godhead was complete. The fact seems to be that the Nestorians assign too literal an interpretation to the maxim of being all things to all men. Centuries of oppression and misgovernment have made them too eager in yielding their opinions to those persons with whom they converse, if the latter happen to be superior in station." They offer animal sacrifices to remove sickness. The laity receive communion in both kinds, and there is probably a belief in transubstantiation. They read the Scriptures a great deal, and pray to the saints, but admit no pictures or images in their churches except the image of the cross. The church service is in old Syriac, and there are translations for the use of the people. On the whole the Nestorian church seems to be in a degraded and lifeless condition; but Roman Catholic and Protestant missionaries, chiefly French and American, have labored among them of late years with great success. A Nestorian bishop, Mar Yohannan, visited the United States in 1842-'3, and preached in several Protestant churches.—See "A Residence of Eight Years in Persia among the Nestorian Christians" by the Rev. Justin Perkins (8vo., Andover, 1843).

NET, a fabric of threads woven in open meshes, and used for ensnaring birds, fishes, and wild animals. The contrivance is of very ancient date, as appears from the allusions to it in Isa. xix. 8, 9, but more especially in the representations of nets and of the modes of using them by the ancient Egyptians, preserved upon their monuments. They appear to have been the most efficient means these people possessed of securing game of all kinds; and they consequently had the greatest variety of nets, and of all sizes, sufficient even to enclose considerable tracts of land, into which they drove antelopes and gazelles, and sometimes hyenas and jackals. The animals, being thus confined, became an easy prey to the hunters. Their net for birds was ingeniously contrived, so that when spread and the birds had collected over it, the two sides could be made to collapse by the persons in charge suddenly drawing a rope attached to it. Fishing nets were furnished, as are those of the present day, with wooden floats along one side, and leaden weights for sinking the other; and they were drawn together with the fish they enclosed by numbers of men upon the shore. Large nets are now employed for

taking shoals of fish off our coasts, as menhaden for manure, by means of two boats sailing in company and spreading the net between them, weighted along one edge. The fish swimming near the top of the water are arrested in their course, and caught as in a bag by drawing up the lower edge to the surface, the two boats gradually closing together. Gill nets are set across waters frequented by fish, which are caught in the meshes by running their heads through, and the gills preventing their withdrawing them.

NETHERLANDS, or **Low Countries** (Dutch, *Nederlanden*; Fr. *Pays-Bas*), a country in the W. of Europe, formerly comprising Belgium as well as the present kingdom of Holland or of the Netherlands, to which the name is now politically restricted. The Dutch term *Nederlanden*, like the French *Pays-Bas*, signifies low lands or low countries, and is applied to this region because a large portion of the surface is a dead plain, and much of it lies below the level of the sea, from which it is protected partly by natural sand hills and partly by vast artificial dikes or embankments. The Netherlands, in the broadest sense of the term, is bounded N. and W. by the North sea or German ocean, E. by Hanover and Prussia, and S. by France, from which countries it is not separated by any great natural barriers. It is the western termination of the vast plain which stretches across Europe from the German ocean to the Ural mountains. Three great rivers, the Rhine, the Meuse, and the Scheldt, flow through it, and their mud, mixing with the sand banks thrown up by the ocean around their mouths, has formed the country, which is nothing but the delta of those rivers. It was by nature a wide morass, which man has made fertile and habitable by laboriously protecting it by embankments from the overflow of the rivers and the frequent inundations of the sea. At present this region is divided into two kingdoms of nearly equal size, Holland in the north and Belgium in the south. (See *Belgium*.)—Holland, or, as it is officially styled, the kingdom of the Netherlands, lies between lat. 51° 15' and 53° 50' N., and long. 3° 30' and 7° 12' E., and is bounded N. and W. by the North sea, E. by Hanover and Prussia, and S. by Belgium. Its length from N. to S. is about 160 m. and its breadth from 60 to 120 m., with an area of 13,890 sq. m. It is divided into 12 provinces, which with their respective populations are as follows:

	Pop. in 1852.	Pop. in 1859.
North Brabant.....	405,687	414,470
Gelderland.....	388,894	408,973
South Holland.....	584,008	637,684
North Holland.....	504,006	548,048
Zealand.....	163,818	166,438
Utrecht.....	153,946	163,249
Friesland.....	255,915	273,910
Overijssel.....	294,773	306,769
Groningen.....	195,264	208,514
Drenthe.....	86,736	95,128
Limburg.....	210,375	217,317
Luxemburg.....	194,619	195,023
Total.....	3,508,635	3,543,775

Luxemburg, which like the greater part of Limburg belongs to the German confederation, is geographically detached from the rest of the kingdom, and is surrounded by Prussia, Belgium, and France. The provinces are divided into 1,209 communes, which include 87 cities. Holland possesses important colonies in various parts of the world, whose aggregate population far exceeds that of the mother country. The principal of these are: in the East Indies, Java, Madura, Banca, Ternate, Amboyna, Banda, Timor, and extensive territories in Sumatra, Borneo, Celebes, and New Guinea, with a total population in 1856 of 16,854,000; in America, Surinam, Curaçoa, and the islands of St. Eustatius, St. Martin, and Saba, with a total population of 82,761; and in Africa, a few posts on the coast of Guinea, with about 100,000 inhabitants. The entire population of the monarchy somewhat exceeds 20,000,000. The Hague is the capital of the Netherlands, and the other principal cities are Amsterdam, Rotterdam, Utrecht, Leyden, Groningen, Haarlem, Maastricht, Leeuwarden, Bois le Duc, and Breda.—The sea coast of Holland is lined in great part by sand banks cast up by the waves of the ocean, and, where these have not been formed, by vast dikes, built partly of granite blocks brought from Norway, and partly of timbers, faggots, turf, and clay. These embankments are usually 80 feet high, 70 feet broad at the bottom, and wide enough at the top for a roadway. They have been constructed by the labor of many generations, at a cost estimated at not less than \$1,500,000,000, and are maintained by an annual expenditure of upward of \$2,000,000. Great pains and much expense are bestowed to keep them in order, and their supervision is intrusted to a board of commissioners, under whom there are many boards of sub-commissioners for particular districts, who from time to time report to the central board the condition of the dikes under their care. (See *Dike*.) The principal rivers of the Netherlands are the Rhine, the Meuse, the Scheldt, and the Vecht, though only the lower parts of these streams are within the limits of the country. The Rhine enters from Germany on the W. with a breadth of nearly $\frac{1}{2}$ m., and divides into two branches, of which the southern, taking the name of the Waal, runs almost due W. for a considerable distance till it joins the Meuse. The N. branch, after running N. W. a few miles, divides into two streams, of which one, called the Leck, runs W. and joins the E. branch of the Meuse near Rotterdam; and the other, called the Yssel, runs N. and falls into the Zuyder Zee. The Meuse enters Holland from Belgium near the S. E. corner of the kingdom, and flows at first N., then N. W., and finally W., and at Gorkum divides into two branches, one of which, the Merwe, again divides, and after flowing around the island of Ysselmonde falls into the North sea; the other branch, flowing more to the S., also divides into two small-

er streams and falls into the same sea. The Scheldt enters Holland from Belgium in the S. W. and divides into two branches, one of which, called the Eastern Scheldt, flows N. between Zealand and North Brabant, and then W. by many channels, enclosing numerous islands, to the sea; the other branch, called the Western Scheldt, flows W. in a broad estuary to the sea. The Vecht enters Holland from Germany on the N. E., and falls into the Zuyder Zee at no great distance from the mouth of the Yssel. All these rivers are kept within prescribed channels by embankments, and are connected by canals, which serve not only for navigation but to prevent inundations by draining off the superfluous waters. Holland originally abounded in lakes, about 90 of which have been artificially drained and converted into cultivable land, while others by inundations have been changed into gulfs of the sea. Among the latter is supposed to be that great inlet of the German ocean, the Zuyder Zee, which covers about 1,200 sq. m. in the N. part of the kingdom, and is thought to have been originally a large fresh water lake. The lake of Haarlem, before it was drained, was about 15 m. in length and 7 in breadth. The Dollart, a lake between Groningen and Hanover, was formed by irruptions of the sea in 1277 and 1287, and occupies about 60 sq. m.—The surface of the country in Holland is almost everywhere a dead level, and such natural elevations as exist are little more than small sandy hillocks. The monotony of the surface is, however, relieved by the numerous canals crossed by frequent bridges, and lined with willows and other trees, with which also the roads are bordered; by large and handsome towns at short intervals; and by countless villas and farm houses, all of which are kept in a state of the utmost order and neatness. The country is everywhere well peopled, and no population in the world exhibit a more uniform appearance of wealth, comfort, and contentment. The soil is naturally poor, but by cultivation has been rendered rich and productive. Wheat, rye, barley, oats, peas, beans, buckwheat, madder, rape seed, hops, tobacco, clover seed, mustard seed, flax, and hemp are extensively raised. The annual average crop of the cereals is about 16,000,000 bushels, and of potatoes about 20,000,000 bushels. The horticulture of Holland has long been famous, and among the flowers tulips and hyacinths are especially cultivated. Pulse and garden vegetables are everywhere raised in great abundance. Very large orchards of apple, pear, and cherry trees are found, especially in Gelderland. The greater part of the soil, however, is devoted to pasturage, for which it is admirably adapted. In South Holland the pasture land is twice as extensive as the arable, while in Friesland the proportion is more than 8 to 1, and the rearing of live stock and dairy husbandry are more productive and profitable than tillage. Upon the excellent meadows created

by draining bogs and lakes vast herds of cattle, brought from Denmark and Germany in a lean state, are fattened for market. Immense quantities of butter and cheese of the best quality are produced and exported at high prices. The annual value of these two articles is frequently as high as \$35,000,000. Another important product of the soil is peat of a most excellent quality, which is largely used for fuel, and of which extensive beds exist.—The climate of Holland is variable, and subject to great extremes of heat and cold. The temperature has sometimes fallen to 23° below zero, and risen to 102°. In winter the rivers and canals are generally frozen for about 3 months. The country is subject to violent gales; the atmosphere is generally damp, dense fogs prevail, and agues, pleurisies, and rheumatisms are frequent. Consumption, however, is not a common disease. The pleasantest months are September and October. From the nature of the soil, which is almost everywhere alluvial clay and sand, there are necessarily no mines in Holland, though a little bog iron has been found. The eastern provinces have some forests of oak, elm, and beech, but in general the country is destitute of trees except those which have been planted by man. Plantations, however, are very numerous, and serve greatly to embellish the vicinity of the towns and villages, the level scenery being beside diversified by groups of wind mills, mostly employed in draining the low grounds. There are no large wild animals and few game birds, though hares and rabbits are plentiful. Storks are very numerous, and remain from the middle of February till the middle of August. They are favorites with the people, and severe penalties are imposed on those who destroy them. Water fowl are extremely abundant, and the waters of the coast are frequented by vast shoals of cod, turbot, and other fish.—The population of Holland is composed mainly of Dutch, with about 700,000 Walloons, Frisians, and Germans, and about 65,000 Jews. The Dutch belong to the great Teutonic family of mankind. The men are generally of middle stature, stout form, and fair complexion. The women are tall and handsome, are very domestic in their habits, and pay the most scrupulous attention to the cleanliness of their houses. Sobriety, steadiness, economy, perseverance, and industry are the most striking features of the national character. Even the youth of both sexes are as sedate and cautious as the older people of other nations. Smoking is very common even among the women. Brandy, gin, and beer are favorite beverages, but intoxication is said to be very rare. "Nothing," says Mr. Nicholls, "can exceed the cleanliness, the personal propriety, and the apparent comfort of the people of Holland. I did not see a house or a fence out of repair, or a garden that was not carefully cultivated. We met no ragged or dirty persons, nor any drunken man; neither did I see any indication that drunkenness is the vice of any

portion of the people. The Dutch appear to be strongly attached to their government, and few countries possess a population in which the domestic and social duties are discharged with such constancy. A scrupulous economy and cautious foresight seem to be the characteristic virtues of every class." There is great wealth in Holland, and it is widely diffused among the people, but there is little ostentatious display of it. The people generally live well and comfortably, but frugally. The houses in the towns are plainly built and furnished. The country abounds in villas called *lusts* or pleasure houses, which are usually built of brick, plastered and painted, and kept in the utmost neatness and order.—There are upward of 600 ship yards in the country, and 220 vessels, with an aggregate tonnage of 54,636 tons, were launched in 1854. The brick manufactories are about 850 in number, the oil mills 312, and the tobacco manufactories 285. The fabrication of earthenware at Delft is extensive and celebrated. Holland has long been noted for its distilleries of spirits, and especially of gin, for which Schiedam is peculiarly famous. In 1853 there were at that place 172 distilleries, employing 615 men. The number in the whole country was 824, and of breweries 376. There are 27 sugar refineries, of which 8 at Amsterdam in 1853 refined 88,000,000 lbs. of sugar. The manufacture of paper is extensive, and there are in the provinces of Friesland, Groningen, Gelderland, and North Brabant upward of 600 establishments for the manufacture of shoes for exportation. The Dutch linens are of superior quality, and the manufacture of linen and cotton goods is carried on extensively in most of the provinces, in establishments numbering in all upward of 500. At Tilburg there are woollen manufactories employing 3,300 persons, and there are extensive silk manufactories at Amsterdam, Haarlem, and Breda. The fisheries of Holland were long famous for their extent and productiveness, especially the herring fishery, which has been carried on since the 12th century, and has been termed the Dutch gold mine. It is a common saying among the people, that "the foundations of Amsterdam are laid on herring bones." In the middle of the 18th century the number of men employed in the herring, cod, and whale fisheries was computed at 100,000. But of late years the fisheries have greatly declined, and in 1854 the number of vessels of all kinds employed was 1,375, of men 7,753, and the value of the produce about \$15,000,000.—The commerce of Holland, though not as extensive as formerly, is still great and active. In 1857 the imports were valued at 413,682,840 florins, and the exports at 843,332,758 florins. It was carried on chiefly with Great Britain, Germany, Java, Belgium, France, and Russia. The exports to the United States were valued at 7,651,706 florins, and the imports at 9,345,084 florins. Butter and cheese are among the largest articles of export; of the former about

12,000 tons are exported annually, and of the latter about 20,000 tons. The mercantile marine of Holland in 1859 comprised 2,488 vessels, with an aggregate tonnage of 587,184. In 1858 the entrances of shipping into the Dutch ports amounted to 9,805 vessels of 1,664,200 tons, and the clearances to 8,896 vessels of 1,700,249 tons.—A system of railroads, with an aggregate length of 422 m., connects Amsterdam with Haarlem, the Hague, Rotterdam, and Antwerp on the one hand, and with Utrecht, Arnheim, and Prussia on the other. The internal intercourse and commerce of the country, however, are chiefly carried on by means of the canals, which communicate with the Rhine and other large rivers, and afford an easy and cheap conveyance for merchandise and passengers. The usual mode of travelling on the canals is by *trekschuits* or draught boats, which are dragged by horses at the rate of 4 m. an hour. The principal canal is called the Helder, and runs N. from Amsterdam to the harbor of Nieuwediep on the Helder point, where it joins the sea, and thus affords Amsterdam an easy intercourse with the ocean. The dimensions of this canal are so great that two frigates can pass each other. Its length is 51 m., and its cost was about \$4,000,000. It was constructed between 1819 and 1825.—A large part of the foreign commerce of Holland is conducted by the *Handel Maatschappij*, or trading association, which in 1824 took the place of the Dutch East India company, which had for two centuries monopolized the trade with the East. (See EAST INDIA COMPANIES.) The *Handel Maatschappij* is the agent for the sale of the government colonial produce in Europe, of which it is also the carrier, and farms some branches of the public revenue of the East India colonies. Two thirds of the exports of the colonies pass through its hands, though it has no exclusive trading privileges. Another great association is the "Society for the Promotion of the Public Good," which was organized in 1784 by a few benevolent persons, and has spread till it has 220 branches throughout Holland, with about 14,000 members, each of whom contributes to its funds a small sum annually. Its object is to promote the establishment of schools, hospitals, asylums, and other works of public utility. Its sections hold meetings once a fortnight, at which questions and measures tending to advance the common welfare are discussed, politics and ecclesiastical matters being excluded. Institutions for the relief of the destitute and suffering are abundant, though in general the poor are taken care of by the churches to which they belong. In 1853 there were 7,410 charitable and benevolent associations, including 494 hospitals, 41 lying-in hospitals, 59 infirmaries, 188 asylums, 2 institutions for the deaf and dumb, 2 for the blind, 40 for employing poor laborers, and 47 for the relief of poor travellers. There are 3 great almshouses, one each at Amsterdam, Middelburg, and Groningen, which afford shelter,

food, and clothing to a large number of persons. Pauper colonies have also been formed on the waste lands of the country, and the able-bodied men employed in reclaiming them. The expense of these colonies is about \$1,000,000 per annum, and the total annual revenues of the charitable institutions of the kingdom exceed \$5,000,000.—Education is provided for by the government, and is under the care of the department of the interior. There are 8 universities, at Leyden, Utrecht, and Groningen, which together in 1858 had 1,551 students. At Amsterdam and Deventer there are collegiate institutions called *Athenæums*, and there are seminaries and primary schools throughout the country, to the number in 1854 of about 4,000, with 466,100 pupils, or about 1 in 7 of the whole population.—By the constitution of Holland full religious liberty is guaranteed to the people, and all churches are equal before the law. In 1854 the population was thus divided: Protestants, 1,985,422; Roman Catholics, 1,201,891; Jews, 62,610; and there were 1,479 persons whose religion was undetermined. The government pays the salaries of all ministers, priests, and rabbis of recognized congregations. Four fifths of the Protestants adhere to the Reformed church of Holland, which holds to the "Confession of Faith" drawn up in the 16th century according to the doctrines of Zwingli and Calvin. It has a presbyterian form of government, and is ruled by a consistory in each congregation, by classes composed of the ministers of several contiguous parishes, together with one elder from each, by provincial synods, and by a general synod which meets annually at the Hague. The number of ministers in the church is about 1,700. There is a Roman Catholic archbishop at Utrecht, bishops at Haarlem, Breda, and Roermond, and two coadjutors, one to the archbishop and one to the bishop of Breda. The majority of the Roman Catholics are in North Brabant and Limburg. The Lutherans number about 820,000, the Baptists 115,000, and the Remonstrants 88,000.—The government of the kingdom of the Netherlands is a constitutional monarchy, of which the crown is hereditary in the house of Orange. All the inhabitants without distinction are entitled to protection for person and property, and all natives are eligible to offices and public employment. Freedom of the press and the right of the people to assemble and to petition are inviolable. The eldest son of the king bears the title of prince of Orange. The king possesses the executive power, declares war, concludes peace, and makes treaties, commands the army and navy, fixes the salaries of all officers, and confers titles of nobility. He proposes projects of law to the legislature, whose chambers he can dissolve at pleasure, though he must command new elections in the course of 40 days after the dissolution, and must convene the new chambers within two months. He has a council of state, consisting of 10 members appointed by himself, which must be con-

sulted about every law and every measure of general interest. The departments of the ministry are not fixed by law; in 1860 it comprised departments of the colonies, of foreign affairs, finances, marine, war, justice, of the interior, of Roman Catholic worship, and of Protestant and other worship. The king, the ministers, a secretary, and two royal princes constitute at present the 18 members of the cabinet council. The legislative power is intrusted to the states-general, composed of two chambers. The members of the upper house, 89 in number, are elected by the provincial states for a term of 9 years, a third of their number retiring every 3 years. Their president is appointed by the king once a year. The members of this house are selected from the class who pay the highest amount of direct taxes. The following is the ratio of their distribution among the provinces: North Brabant, 5; North Holland, 6; Friesland, 8; Drenthe, 1; Gelderland, 5; Zeeland, 2; Overijssel, 8; Limburg, 8; South Holland, 7; Utrecht, 2; Groningen, 2. The province of Luxemburg, the whole of which belongs to the German confederation, is not represented in the states-general. The members of the lower house are 68 in number, and are chosen for 4 years from 38 electoral districts, to which they are assigned in the ratio of one representative to 45,000 inhabitants, Amsterdam having 5 representatives. They are chosen at biennial elections by electors who must be 23 years of age and pay taxes varying in different districts from about \$8 per annum to about \$65. Each member is paid a salary of about \$850 a year and his travelling expenses. The speaker of the house is appointed by the king. The king's ministers have a right to sit and speak in either house, but not to vote. The states-general meet at the Hague every year on the 3d Monday in September, and hold their sessions in public. They are obliged by law to sit at least 20 days. A majority is required for a quorum; and no measure can be enacted without the assent of an absolute majority of each house. In each province there are provincial "states," which are legislative and administrative bodies. Beside electing the members of the upper house of the states-general, they are charged with the execution of the laws of the kingdom within their limits, and have power to make special and local laws, which, however, are subject to the sanction or veto of the king. The internal police of the provinces is left to their superintendence. The king appoints a commissioner to preside over their sessions, which are held semi-annually. The members are elected for 6 years at triennial elections, by the same constituencies that elect the members of the states-general. The number of the members of these provincial legislatures varies in each province, that of South Holland, which is most numerous, having 80 members, and that of Drenthe, the smallest, 85. The communes into which each province is subdivided are governed also by local councils elected by the people for a term of years.

In 1859 the public debt of the kingdom amounted to 1,086,343,830 florins. The receipts were 78,575,364 florins, and the expenditures 77,425,241. The receipts of the colonial administrations in 1857 were 82,392,641 florins, and the expenditures 83,209,839. The army in 1859 comprised 58,743 men; and the navy, July 1, 1859, consisted of 83 vessels carrying 1,740 guns, of which 14 were war steamers mounting 94 guns. There were beside about 70 gun boats. The fleet is manned by 6,221 men, including 2,158 marines.—Justice is administered by various courts, the chief of which is the high court of the Netherlands, consisting of a president, vice-president, and 12 judges, appointed by the king from 8 candidates presented to him for each vacancy by the lower house of the states-general. The judges hold office for life. The court hears appeals from the lower courts. All causes in which the state is defendant are tried before this court, and the high functionaries of government are amenable to it only. There is also a provincial court in each province, and subordinate to them district courts, which have each from 5 to 14 judges. In 1853 the number of prisons of all kinds amounted to 216, with 4,087 inmates. There is an excellent prison for male juvenile delinquents at Rotterdam, and another for young females at Amsterdam, which are admirably managed and serve as schools for intellectual and religious training.—The first historical notice of the Netherlands which has come down to us is contained in Cæsar's account of his wars with the Belgæ, the Nervii, and other barbarian tribes who inhabited its morasses. These tribes were mostly of Gallic race, though in some parts of the country several clans of Teutonic origin had established themselves, pre-eminent among whom were the Batavi, whom Tacitus calls the bravest of all the Germans, and who in fact were always spoken of by the Romans with marked respect. They were the allies, not the subjects of the Romans, and a Batavian legion formed the body guard of the emperors down to the times of Vespasian. During the civil war between Vespasian and Vitellius, Claudius Civilis, a Batavian who had served for many years in the Roman army and had received a Roman education, organized a general confederation of all the Netherlands tribes against the Romans; but after a heroic struggle, the insurgents were crushed by the armies of Vespasian, who had now attained the purple, and the Netherlands remained among the provinces of the empire till they were overrun by the northern barbarians in the 5th century. The Batavi still formed the bravest portion of the Roman forces, and their cavalry was particularly distinguished. In the great battle at Strasbourg between the Germans and the army of the emperor Julian, about the middle of the 4th century, the Batavian horse saved the day for the Romans. This was the last of their achievements mentioned in history, and soon afterward the Batavian na-

tion seems to have lost its individuality and to have become merged, together with the Belgæ, in the Frank and Frisian tribes who had invaded and occupied the country. The monarchy of the Franks in the 6th and 7th centuries embraced the whole of the Netherlands. In the 8th century the Frisians revolted, but were routed by Charles Martel in a great battle in 750, and were soon afterward converted to Christianity. At the beginning of the 9th century they formed a part of the empire of Charlemagne. A century later, under the influence of the feudal system, the whole of the Netherlands was in the possession of a number of princes, owning a limited species of allegiance, some to the German empire, and some to the kings of the Franks. In 922 Charles the Simple created by letters patent the first count of Holland, and the dukedoms of Brabant, Luxemburg, Limburg, and Gueldres; and the countships of Flanders, Zealand, Hennegau, Artois, Namur, and Zutphen were established before the 18th century. The most powerful of these potentates was the count of Flanders, whose dominions in 1383 fell to the house of Burgundy; and in 1437 Philip the Good, duke of Burgundy, became master of the entire Netherlands. At this period the country had already become rich and populous, and the commercial cities had acquired a controlling influence in the government, and within their own limits enjoyed almost republican freedom. The states-general, as the parliament was called, held the purse strings of the country, and granted money to the sovereign only when they themselves saw fit. Under the house of Burgundy the Netherlands became the most opulent and populous part of Europe; and their chief cities, Antwerp, Ghent, and Bruges, were especially distinguished for wealth and splendor. By the marriage of Mary of Burgundy, daughter of Charles the Bold, with Maximilian, archduke of Austria, Aug. 18, 1477, the Netherlands became a possession of the house of Hapsburg. Her grandson, the emperor Charles V., resigned them to his son Philip II. of Spain in 1555. At this period the Netherlands comprised the dukedoms of Brabant, Limburg, Luxemburg, and Gelderland; the countships of Artois, Hennegau, Flanders, Namur, Zutphen, Holland, and Zealand; the baronies of Friesland, Mechlin, Utrecht, Overysse, and Groningen; and the margraviate of Antwerp—in all, 17 provinces. They were reported to contain 350 cities, and 6,300 towns and large villages, beside hamlets, castles, and farm houses. Though these statistics are doubtless exaggerated, it is certain that no other part of Europe was so rich or so densely peopled. The commerce, the manufactures, and the agriculture of the country were highly flourishing; and in spite of occasional troubles and violent contests between the sovereigns and the people, the taxes of the Netherlands were not excessive and the privileges of the provinces not seriously impaired

under the rule of Philip's predecessors. The reformation had made considerable progress among the people during the reign of Charles V., chiefly in the cities, and Philip soon after his accession undertook to root out entirely the new doctrines, and to restore the exclusive supremacy of the Roman Catholic church. His father's abdication was carried into effect in the Netherlands, and from the time of his accession in 1555 Philip remained in the country till Aug. 1559, when he departed to his Spanish dominions never to return. He left the Netherlands under the government of his sister Margaret, duchess of Parma, as regent, assisted by Granvelle, bishop of Arras, afterward cardinal, a native of France, who was greatly detested by the people. Three native nobles of the highest rank and character, William of Nassau, prince of Orange, and the counts Egmont and Horn, were nominally associated with Granvelle as councillors of state; but by secret orders from Philip they were deprived of all practical power in the administration, which was wholly in the hands of Granvelle. The arrogance of Granvelle and the attempt to introduce the inquisition provoked a determined resistance, which was headed by the prince of Orange, Egmont and Horn, and other great nobles. An insurrection of the Protestants broke out in Flanders, Aug. 14, 1566, and lasted about a fortnight, during which great ravages were committed on the churches and monasteries. (See *ICONOCLASTS*.) This outbreak, which was temporarily suppressed by the influence of William of Orange and Egmont and Horn, and by concessions from the frightened duchess of Parma, determined Philip to resort to the most severe measures to suppress Protestantism; and accordingly the cruel duke of Alva, a soldier of great reputation, was sent to the Netherlands in 1567 with a powerful army of Spanish veterans. Egmont and Horn were arrested and beheaded at Brussels, and also many other noblemen of distinction, and for 6 years the country suffered under a tyranny which for extent and ferocity has few parallels in history. The prince of Orange withdrew to Germany, and appealed to the Protestant princes of that country for aid. They allowed him to raise a force of volunteers, and gave him some pecuniary assistance, as did also Queen Elizabeth of England. He reentered the Netherlands in the latter part of 1568 at the head of an army, and called his countrymen to arms. A long war ensued, distinguished by sieges rather than by battles, and marked by various fortune on both sides. The states of Holland and Zealand conferred almost dictatorial powers on the prince of Orange, with the title of stadtholder; and those provinces equipped a powerful naval force which greatly contributed to the ultimate defeat of the Spaniards and the achievement of Dutch independence. The severity of Alva having driven the greater part of the Netherlands to insurrection, and his attempts to suppress the revolution by

force of arms having entirely failed, he was recalled, and departed in Jan. 1574. His successor, Requesens, was instructed to adopt a milder system of government; but he met with little success, and died of fever toward the end of 1575. The famous Don John of Austria, the victor of Lepanto, succeeded him as viceroy; but after gaining several victories over the revolutionary forces, he too died of fever or of poison, Oct. 1, 1578. He was succeeded as regent by his nephew the duke of Parma. In the following year the provinces of Holland, Zealand, Utrecht, Friesland, Groningen, Overijssel, and Gelderland formed the union of Utrecht, and thus laid the foundation of the republic of the Seven United Provinces. From this period the history of the Netherlands divides itself into that of Holland and that of Flanders, or the 10 provinces which remained under the Spanish dominion and adhered to the Roman Catholic faith, and now constitute the kingdom of Belgium. (See *BELGIUM*.) William of Orange was assassinated at Delft, July 10, 1584, by a fanatical partisan of Spain named Balthasar Geerardt or Gérard. The death of this illustrious hero and statesman, who ranks among the greatest men in history, was a terrible loss to the struggling commonwealth, which owed its existence mainly to his extraordinary wisdom, prudence, and firmness. The Dutch patriots, however, did not despair. They continued the contest with unabated courage and energy, and finally with a success truly astounding when we consider the power and resources of Spain, at that time the first power in the world. Prince Maurice, a son of the murdered statesman, though only 17 years of age, was chosen to succeed his father, and by his military genius and success amply justified the choice of the people. He proved to be one of the greatest generals of modern times, and his career till his death in 1625 was an almost unbroken series of battles, sieges, and victories. About this time the sovereignty of Holland was offered to Elizabeth of England, who declined it, but sent the earl of Leicester to the assistance of the Dutch with a body of troops. Leicester, however, effected little, and was recalled in disgrace in 1587. Philip II. died in 1598, and his successor Philip III. for some years continued the effort to subdue the rebellious Hollanders. But the Dutch by this time had created a fleet that made them the first naval power of the world. Their ships were manned by 70,000 hardy and daring seamen, who swept the remotest seas of Spanish commerce, and finally so impoverished the king of Spain by intercepting the remittances of treasure from the colonies, that at length in 1609 he agreed to a truce for 12 years. During the peace internal dissensions broke out in Holland between the Calvinists and Arminians, whose theological differences were made the basis of political parties, who contended for their respective tenets with great zeal and bitterness. These

disensions were fomented by the ambitious Maurice, who aspired to become hereditary sovereign of Holland, and was already by his influence over the army exercising a species of dictatorship. He was opposed by the venerable Barneveldt, one of the most illustrious of the Dutch statesmen, who had rendered the most signal services to the republic, and was the head of the Arminian party, or as they came to be called the Remonstrants, from a remonstrance which they published in favor of universal toleration. The Calvinist party, of which Maurice was chief, were soon known as Anti-Remonstrants, and those names continue to be used in Holland to the present day. The Calvinists prevailed in the contest for the political supremacy, and Barneveldt and the famous Grotius, another eminent leader of the Remonstrants, were arrested on charges of treason. After an infamous trial, in which party spite and popular clamor were brought to bear on the judges, Barneveldt was condemned and executed, May 18, 1619, at the age of 70 years. Grotius by an artifice escaped from prison, and took refuge in France. On the expiration of the truce in 1621, the war with Spain was renewed. After the death of Maurice, who was succeeded by his brother Henry, operations on land were not for some time prosecuted with much vigor, but on sea the Dutch displayed great energy. They attacked Peru with success, and conquered St. Salvador and a large portion of Brazil, which at that period belonged to the Spanish monarchy. They also made incessant attacks on the Spanish possessions in the East Indies, and laid the foundations of the Dutch empire in that part of the world. On the general pacification of Europe by the peace of Westphalia in 1648, a final treaty was made with Spain, which at length acknowledged the independence of Holland after it had been practically maintained for 70 years. A few years later the republic became involved in war with the English commonwealth, and several great naval battles were fought between the celebrated Dutch commanders Van Tromp, De Ruyter, and De Witt, and the famous English admiral Blake. In a tremendous engagement near the Goodwin sands, Dec. 9, 1652, the Dutch were victorious, and the triumphant Van Tromp sailed along the English coast with a broom at his masthead to indicate that he had swept the channel of English ships. Another great fight took place in Feb. 1658, between Blake and Van Tromp, which lasted 8 days, and in which both sides claimed the victory. In the following June the fleets, each numbering about 100 vessels, again met, the Dutch commanded by Van Tromp, De Witt, and De Ruyter, and the English by Blake, Monk, and Dean; and after an obstinate battle the Dutch were totally defeated. Undismayed by this disaster, the Dutch sent to sea a still greater fleet in July under Van Tromp, which encountered the English off the coast of Holland. Van Tromp was killed at an early period of the

battle, and the Dutch were again beaten with the loss of 6,000 men. Peace was soon after concluded between the two republics, and Holland immediately engaged in a war with Portugal concerning their respective possessions in Brazil, in which many Portuguese vessels were captured. The war, however, ended by the expulsion of the Dutch from Brazil in 1654. In 1665 Charles II. of England declared war against Holland, and hostilities on the ocean were prosecuted with much vigor, the Dutch fleet under De Ruyter gaining a great victory over the fleet of the duke of Albemarle at the beginning of June, and even threatening to invade England; while in the following month, after another engagement, the Dutch admirals were forced to take refuge in their harbors. In the following year, however, De Ruyter sailed up the Thames with his fleet, burnt the shipping at Sheerness and Chatham, and blockaded for a short period the port of London. A month later the peace of Breda ended the war, and in the beginning of 1668 Holland entered into an alliance with England and Sweden to check the growing power of Louis XIV. of France, who had seized upon the 10 provinces of the Spanish Netherlands. The fickle and deceitful Charles II., however, being bribed by Louis, ordered a treacherous attack on a rich Dutch fleet from Smyrna, in March, 1672, which was bravely repulsed. Three days afterward he declared war against his late allies, and sent a force to cooperate with the French. Sweden also joined the league against the Dutch, and Louis invaded Holland at the head of 120,000 men commanded by the first generals of the age, and in a few days conquered the provinces of Utrecht, Gelderland, and Overysseel. The Dutch, whose forces did not exceed 25,000 men, were beside divided and weakened by the most violent contests between the partisans of the house of Orange and the opponents of that party, headed by the grand pensionary John De Witt and his brother Cornelius, by whose influence the office of stadtholder had been abolished in 1650 and the states-general made the supreme power. The partisans of De Witt proposed to remove the whole nation to the East Indies rather than submit; but the young prince of Orange, William III., afterward king of England, encouraged the people to resist, and declared he would die in the last ditch. He was made stadtholder by acclamation, was intrusted with dictatorial power, and the De Witts were massacred by a mob at the Hague. The desperate resolution was taken to cut open the dikes and let in the ocean to drown the country and its invaders. This expedient was successful, and the baffled French were forced to retreat with great loss. Peace was restored in 1674. In 1677 the prince of Orange, who continued to hold supreme and almost absolute power in Holland, was married to the princess Mary, daughter of James II. of England, and attained the throne of England by the revolution of 1688. During his life, and for several years after his death

in 1701, Holland bore a conspicuous part in the wars that were waged by the European powers against France to check the ambitious projects of Louis XIV. On the death of William III, the anti-Orange party prevailed in Holland, and no stadtholder was appointed, except in the province of Friesland, which recognized the hereditary claim of his cousin John William, surnamed Friso. The republic was governed by the states-general, the grand pensionary, as the chief executive was styled, being till his death in 1720 the eminent statesman and diplomatist Heinsius. In 1747, the Orange party having regained the ascendancy, William IV. was made stadtholder of the republic; and on his death in 1751 his infant son William V. succeeded to the office, which he held till 1795, when Holland was conquered by France, and the Batavian republic established. During the 7 years' war, from 1758 to 1768, Holland remained neutral; but in the progress of the American revolution she became involved in war with England, and her fleet sustained a severe defeat from the English on the Dogger bank in 1782, after a bloody fight. The French revolution found warm partisans in Holland among the anti-Orange faction, and their sympathy and assistance, together with an intense frost which enabled the French army to pass the rivers and canals on the ice in the winter of 1794-'5, rendered the conquest of Holland by Gen. Pichegru an easy task. The Batavian republic, which in its closing years was administered by the director Schimmelpenninck, a statesman and patriot of eminent ability and integrity, terminated in 1806 by the erection of Holland into a kingdom, on the throne of which the emperor Napoleon placed his brother Louis. Louis ruled with moderation and kindness, but his preference of the interests of Holland to those of France gave such offence to his imperial brother, that in 1810 he abdicated, and Holland was incorporated as an integral part of the French empire. On the downfall of Napoleon the prince of Orange, who had been in exile in England, was declared king by an assembly of notables, under the title of William I., with a constitution limiting his power within moderate bounds. The 10 ancient provinces which had remained under Spanish rule at the time of the great revolution of the 16th century, and had subsequently belonged to the house of Austria, were annexed to Holland by the congress of Vienna, with the object of forming a power of sufficient force to serve as a check to the progress of France toward the N. E. The difference of race, religion, language, and manners, however, prevented the assimilation of the two sections into one nation; and on the outbreak of the French revolution of 1830 the 10 southern provinces revolted, and, aided by the French, established their independence as the kingdom of Belgium, with Leopold of Saxe-Coburg as king. Since the separation Holland has continued flourishing and peaceful, and has made rapid advances in prosperity and opulence. In 1848, after the

French revolution of that year, the constitution was still further liberalized, and extensive reforms were introduced. William I. abdicated in 1840 in favor of his son William II., who died in 1849, and was succeeded by William III., the present king.

NETHERLANDS, LANGUAGE AND LITERATURE OF THE. The origin of the Dutch language has been the subject of considerable controversy. The philologists of the last century derived it directly from the old Frisian, which they regarded as holding the same relation to it that the Anglo-Saxon does to the English. Rask was the first to declare that this view was not wholly correct. He supposed that the modern Dutch was indeed, at first, a development of the old Frisian, but that this development was arrested, and the current of the language essentially changed, by an irruption at a remote period of Saxons and Franks into the region of the lower Rhine. By this theory he accounted for the presence of such forms as *tand* (tooth) for the old Frisian *tôth*, and *doen* (do) for the old Frisian *dûa*. More recent investigations, however, have shown that many of the Dutch inflectional forms are at least as old as the corresponding Frisian ones; thus the Dutch infinitives and weak substantives end in *en*, a termination certainly not younger than the Frisian one in *a*. The inference is, therefore, that a single language, belonging to the Low German division of the Teutonic group, was originally common to both Friesland and Holland; that this was spoken in two dialects; and that the northern of those dialects became the modern Frisian of Friesland, while from the southern came the modern Dutch of Holland. The Dutch seems also to contain a few remains of the Belgian dialect of the very ancient tongue spoken by the old Gallic tribes, such as the possessive pronoun *hun* (their). It is less sonorous but softer than the Upper or High German, from which it especially differs in avoiding, as far as possible, all sibilant consonants and hard diphthongs. Its syntax is very similar to that of the German. The most striking characteristics of the Dutch are its descriptive energy and its power of composition. In this latter respect it excels all the modern members of the Gotho-Teutonic family except the Icelandic. Its scientific nomenclature admits not only of such substantives as *sterrekunde* (astronomy; Germ. *Sternkunde*), but of the corresponding adjective forms like *sterrekundig* (astronomical; Germ. *astronomisch*), which in German are generally taken from exotic sources. It is especially rich in terms belonging to commerce and navigation, and to its maritime vocabulary all the northern nations, including the English, are indebted for a multitude of words. The chief dialects spoken in the Netherlands are the Frisian (see **FRISIAN LANGUAGE AND LITERATURE**); the Flemish (see **FLEMISH LANGUAGE AND LITERATURE**); the dialect of Groningen and Overijssel, which approaches nearer than any other to the High

German; and the dialect of Gelderland. The last two have no literature of any note.—The first development of the literature of the Netherlands, about the middle of the 18th century, was Flemish rather than Dutch, and this continued to be the case for more than 250 years. But about 1570 the *rederijkerskamer* of Amsterdam, through the efforts of three men, assumed the character of a literary academy. These were the reformer D. Coornhert (1522-'90), H. L. Spiegel (1549-1612), and Roemer Visser (1547-1620), the real founders of modern Dutch literature. Coornhert's productions are mostly treatises on morality and theology; but one of his poems, *Wilhelmus van Nassauwen*, is still the favorite national song of Holland. The posthumous poem of Spiegel, the *Hertspiegel*, is of an ethic kind. This triumvirate rendered great service by the grammatical works published under their direction by the Amsterdam *kamer*. A linguistic labor of still greater importance was the Dutch-Latin dictionary, begun by the celebrated printer Plantin (1514-'89), and finished by his disciple C. Kilian (died 1607).—At the beginning of the 17th century, and for many years later, Holland, a powerful, wealthy, and free commonwealth, was preëminently the literary country of Europe. The devotion of the learned to the ancient languages was ardent and almost without parallel elsewhere; but a golden age of vernacular literature was ushered in by P. O. van Hooft (1581-1647), who gave a sweetness and harmony before unknown to Dutch speech. His amatory and Anacreontic lines have not been excelled by any later writer; and his *Nederlandse Historien*, embracing the years between 1555 and 1587, is a model of stately historical narrative. J. van Oats (1577-1660), or "Father Oats," as his countrymen love to style him, wrote for the multitude, whose descendants still almost know his poems by heart. Although recent judicious criticism has somewhat modified the fame so long enjoyed by J. van den Vondel (1587-1689), his is still the greatest poetical name of the century. He wrote much, dramas, lyrics, and satires, and had a multitude of disciples and imitators. One of the best is Antonides van der Goe (1647-'84). J. Oudaan (1628-'92) is the author of two dramas worthy of note, *Johanna Gray* and *Koning Konradijn*; and other dramatic writers are G. A. Bredero (1586-1618), S. Coester, W. van der Nieuwlandt (1584-1635), the Fleming J. Zevecot (1604-'46), whose *Belleg van Leyden* ("Siege of Leyden") may still be read with pleasure, and L. Rotgans (1645-1710), whose dramas are much better than his tedious epic, *Willem III*. A man of large learning and much descriptive talent, O. van Huyghens (1596-1687), produced some not unpleasing didactic poems, like the *Zedenprinten* ("Pictures of Manners"), *Hofwijck*, and *Voorhut*, which with others he included in a collection bearing the quaint title *Korenblou-*

men ("Bluebottles"). A rhymed narrative, the *Masker van der Wereld*, by the Flemish Jesuit A. Poirtiers (1606-'75), was once very popular. The *Lof der Feldeucht* ("Eulogy of Avarice") and the domestic elegies of J. de Decker (1609-'66) are yet frequently quoted; *Roselijns Oochies* is a pretty idyllic effusion by D. Joncktyns (born 1600); and the pastoral poems of J. B. Wellekens (1658-1726) are graceful and imaginative. The almost universal use of Latin, as a language through which a vastly larger audience could be reached, left little room for Dutch prose. Several translations of the Bible, both from the original tongues and the Vulgate, some biblical commentaries, and a number of other theological treatises met with a wide circulation. The *Bataafsche Arcadia* of J. van Heemskerk (1597-1656), suggested by the *Decamerone* of Boccaccio, is the only work that deserves the name of a romance. Beside Hooft, the historians are P. O. Bor (1559-1635), E. van Meteren (1585-1612), L. Aitzema (1600-'69), and G. Brandt (1626-'85). The Dutch navigators, as Barentz and Heemskirk in their search for a north-east passage, Gerritszoon in the Australian regions, and Noort and Spilbergen in the extreme Orient, added much to geographical knowledge in this century. Many of these explorers wrote narratives of their voyages, versions of which appeared in various languages. Among these works are J. Nieuwhof on China (1665), P. Baldens on Ceylon and Malabar (1672), M. G. de Vries on Japan (1642), G. Schouten on the East Indies (1696), O. de Bruyn on eastern Europe and western Asia (1698), and W. Bosman on Guinea (1705).—The 18th century offers a marked contrast to its predecessor. The literature of the 17th century gave way in the 18th to imitation of French models. Few authors escaped this contagion. One of these, however, is H. K. Poot (1689-1738), the farmer-poet, whose style is pure and natural, and whose erotic and idyllic verses are marked by ease and liveliness. His most striking pieces, perhaps, are *Wachten* ("Watching") and *Landleven* ("Rural Life"). A biblical epic which has considerable merit, but which was followed by a number of bad imitations, is the *Abraham* of A. Hoogvliet (1687-1763). The *Rottestroom* of D. Smits (1702-'52) also originated a school known as the stream poets, who sang the beauties of all the Dutch rivers. Of the two brothers W. van Haren (1710-'68) and O. Z. van Haren (1718-'79), the elder left a legendary, knightly tale in verse, *Friso*, and some lighter compositions, among which are *Leonidas*, *Menscheijk Leven* ("Human Life"), and the *Hof van den Vrede* ("Court of Peace"); the younger was the author of two tragedies and a lyrical epic, *De Guezen*, woven out of the popular national ballads. A sort of transition poetical period, the dawn of the day of Bilderdijk and Tollens, begins with 1780. It was initiated by J. Bellamy

(1757-'86), whose *Rooze* is the most touching and beautiful ballad in the language, and was further characterized by the astronomer P. Nieuwland (1764-'98), whose *Orion* is a stately and, in some portions, sublime epic, and by H. van Alphen (died 1808), whose poems for children, have been frequently reprinted. The purest prose of the century is that of J. van Effen (1684-1785), who possessed not a little of the humor and grace of his model, Addison, of whose chief work his *Hollandische Spectator* is an imitation. The romance style was developed by two women, A. Deken (1741-1804) and E. Wolff (1788-1804); their novels, written in conjunction, though somewhat diffuse, are successful pictures of Dutch life and manners. The lengthened *Vaderlandsche Historie* of J. Wagenaar (1709-'98) is impartial and trustworthy, but the diction is rather dull and heavy. The other historians are G. van Loon (born 1688), S. Styl (1781-1804), and A. Kluit (1787-1807). The *Vaderlandsche Woordenboek* (1785-1800), in nearly 40 volumes, by J. Kok, is a treasury of information concerning the history and topography of Holland. In philology L. ten Kate (1674-1783) anticipated many of the ideas of Grimm and the later Teutonic school. He and B. Huydecoper (1695-1778), who edited one or two of the old Flemish chronicles, were of great service to their native tongue. D. van Hoogstraaten (1658-1724) attained some eminence as a lexicographer. In science the philosophers W. J. 'sGravesande (1648-1742), N. Hartsoeker (1656-1725), and P. van Musschenbroek (1692-1761) gained a European renown, as did those disciples of Boerhaave, P. Camper (1722-'89) and G. van Swieten (1700-'72). J. Lulof (1711-'68) wrote on geography, and the Schultens and S. Rau were well known as orientlists.—The modern revival of Dutch letters is coincident with the French revolution, having fairly commenced some little time before the opening of the 19th century. Rhynvis Feith (1758-1824) did much toward bringing in this new epoch. His reputation is still maintained by a series of admirable historical odes, including one on De Ruyter, and one entitled *Washington*. The *Taal*, *Schilderkunst*, and other productions of O. Loots (1764-1884) bear much resemblance to the style of Helmers, but are much superior in energy and force. E. A. Borger (1775-1820), a theologian, A. Simons (1769-1884), and J. Kantelaar (1759-1821) have also left several tasteful and polished lyrics. But the greatest of modern Dutch poets, if not of all Dutch poets, is Willem Bilderdijk (1786-1881). Of his multitudinous works, *Leidens Ramp* ("The Disaster of Leyden") is full of spirited action and sustained interest; the *Ziekte der Geleerden* ("Maladies of the Learned") is a powerful treatment of a subject by no means pleasing; and the *Buitenleven* ("Country Life") possesses every beauty but that of originality. His most remarkable composition, however, is

an epic entitled *Ondergang der eerste Wereld* ("Destruction of the First World"), of which only the first 5 books were completed. The same author's *Geschiedenis der Vaderlands*, in prose, has been published since his death by B. F. Tydeman. Another poet of unbounded popularity is H. C. Tollens (1780-1856). Especially admirable are his narrative poem *De Overwintering op Nova Zembla*, an account of Barentz's famous expedition in 1594-'6, his ballads *Jan van Schaffelaar* and *Kenau Hasselaar*, and his stirring national lyric, the *Wapenkreet*. The example and influence of Bilderdijk and Tollens have given birth to a crowd of minor bards. Some of the most meritorious are J. F. Bosdyk (died 1850); B. H. Lulofs (1787-1849), author of the *Watersnood*; W. Merschet (died 1844), whose *De goude Bruloft* is justly praised; H. A. Spandaw (born 1775), of whose works the *Neerlands Zeeroem* and the *Vaderlandsche Poezij* are popular; W. de Olercq (1798-1844), a celebrated improvisator; J. Immerzeel (1776-1841), also known for his biographies of the artists; B. Klyn (1764-1829); A. C. W. Staring van den Wildenborch (1767-1840), the best modern humorist, of whose peculiar manner his *Iamben* and *Zephir en Cloris* are good examples; and P. Moens (1767-1848). Living lyrical and descriptive poets are I. da Costa, a Jew, who, since the decease of Tollens, occupies the highest place in the modern Dutch Parnassus; O. G. Withuys; S. J. van den Bergh; J. van Beers, whose latest volume (1860) is called *Levenbeelden*; J. A. Alberdingk Thym, L. van den Broek, and J. J. L. ten Kate. Among those who wrote for the stage in the latter part of the last century were S. J. Wisselins (1769-1845), J. Nomsz, J. van Walré (1759-1837), H. H. Klyn, and A. Loosjes (1761-1818), the last of whom also gave to the world some pleasant tales and sketches. Still later dramatists are the prolific comedy writer Ruysch and J. Hilman. The novels of E. Kist (1758-1822) and of A. Fokke (1788-1812) are still much read; but they have been excelled by the romances of J. van Lennep (born 1802), a son of D. J. van Lennep (1774-1858). He has published a series of historical tales under the general title *Onze Voorouders*, and some of his works, as "The Rose of Dekama" and "The Adopted Son," have been translated in England and America. He is also the author of a good abstract of the history of Holland, 2 or 3 lively comedies, and many poems. The tales of J. de Vries (born 1774), A. Drost (1810-'84), O. P. E. Robidé van der Aa (1791-1851), P. A. S. van Limburg Brouwer, and C. van Schaick (born 1808), have had a large circulation. As a model of prose style, J. H. van der Palm (1763-1840) is esteemed superior even to Van Effen, while M. C. van Hall (born 1767), J. Kinker (1767-1845) and Amorice van der Hoeven (born 1798) are likewise celebrated as prose writers and orators. J. W. te Water (1740-1822) and J.

Scheltema (1766–1835), in domestic history, and M. Stuart (1765–1826) and H. Muntinghe (1752–1824) in ecclesiastical and universal history, have been accompanied or followed by J. H. Janssens, G. van der Maaten, T. Kunivers, J. C. de Jonge (whose *Geschiedenis van het Nederlandsche Zeewezen* was completed in 1856), J. C. den Beer Portugael, and a multitude of others. Witzén Geysbeek (1779–1833) is the author of a valuable critical anthology of the Dutch poets. Living critics and *littérateurs* are W. J. A. Jonckbloet, whose edition of the *Reinaert de Vos* is the best yet issued, N. Beets, W. J. Hofdyk, A. de Jager, and D. Buddingh. The Dutch dictionary of P. Weiland (1755–1842), founded upon that of Plantin and Kilian, is at present the best lexicographical authority. The orthography of the language, which was previously very unsettled, was rendered uniform by the adoption in the schools, in 1804, of the system proposed by M. Siegenbeek (born 1774), the compiler of several works on the Dutch language and literature. In spite of the opposition of Bolderdyk and others, the new method is now in general use. A. Ypey (1769–1837) and Westreenen de Tillandt have produced some valuable essays on Dutch linguistics, while S. F. W. Roorda van Eysinga, Hoffman, A. Hardeland, and others have written on various foreign languages. Geography is indebted to Hogendorp (died 1835), to Siebold, and to Meylan, well known writers on Japan, and for descriptions of the Dutch East Indies to C. J. Temminck and J. van der Aa. The other sciences are represented by the Vorsts in theology; Mulder, whose chief work has been rendered into English, in chemistry; and the Vroliks, C. L. Blume, and R. B. van den Bosch in the natural sciences. Literary and philosophical societies, publishing valuable transactions, exist in Leyden, Utrecht, Haarlem, and in the Dutch East Indies at Batavia, while the *Koninklijk Instituut*, formed during the reign of Louis Bonaparte upon the plan of the French institute, is the highest scientific authority of the land. The leading critical and learned journal is the *Vaderlandsche Letteroefningen*, established in the last century, and which for many years subsequent to 1803 had a rival styled *Recessant ook der Recensenten*.

NETTLE, the name of various species of the genus *urtica* (Lat. *uro*, to burn), herbaceous plants armed with stinging hairs, contact with which produces a burning sensation. The large stinging nettle (*U. dioica*, Linn.) grows in clusters about the roadsides, with stems from 2 to 6 feet high; its leaves are opposite, heart-shaped, and toothed; its flowers small, obscure, green, borne in axillary panicles, which appear in pairs, spreading and branched. The small nettle (*U. urens*, Linn.) is an annual, appearing in rich gardens as a weed; it has leaves with 3 to 5 nerves, and axillary racemes, which are mostly simple and generally shorter than the leaf stalk; the whole plant is covered with stinging hairs like the preceding. Both are

adventitious from Europe. The tall wild nettle (*U. gracilis*, Aiton) is very distinct from these, with slenderer and long-petioled leaves, smaller flowers, and scarcely any stinging hairs except on the petioles and principal veins of the leaves; it is to be found in the moist grounds of the northern states. The purplish nettle (*U. purpurascens*, Nuttall) has ovate and mostly heart-shaped leaves, globular flower clusters, and a slender stem from 6 inches to 3 feet high, beset with scattered stinging bristles, which are likewise found upon other portions of the plant; it occurs in shady places on the alluvial soils of Kentucky and southward.—The nettles belong to the natural order of *urticaceae*, whose prevailing qualities are acrid and narcotic. The species of this order are widely dispersed over every part of the globe, sometimes found growing in the driest places, and then again in the dampest recesses of the forest. The stinging property of the juice, resident in the hairs, is owing to its excessive causticity; and in some East Indian species this is very remarkable. The wounds from the devil's leaf (*U. urentissima*) are said to have caused death. Some medicinal qualities are attributed to certain other kinds, and the tenacity of the fibres of the stalk of some species affords a kind of hemp used for making lines and cordage. According to Roxburgh, the tuberous roots of *U. tuberosa* are esculent, being eaten raw, boiled, or roasted, by the natives of certain districts in the East Indies. The leaves and seeds of an Egyptian species (*U. membranacea*) are considered as an emmenagogue. The total number of species in the order is supposed to be more than 800.—There are other plants bearing the name of nettle, such as the nettle tree (*celtis*), having leaves resembling some kinds of nettle, but the similarity ends there; and the dead nettles (*lamium*), which however belong to the natural order of *labiata*, or the mint family.

NETTLE RASH (*urticaria*), an exanthem characterized by an eruption of patches whiter or redder than the surrounding skin, and attended with intense itching. The disease has been divided into three varieties: *urticaria febrilis*, *U. evanida*, and *U. tuberosa*. The febrile variety is preceded by a feeling of general uneasiness, headache, nausea, and vomiting. These symptoms are followed by a troublesome itching and the appearance of an eruption, commonly most abundant about the shoulders, loins, or thighs. The patches are irregular in size and form, sometimes rose-colored with whitish border, sometimes white with rose-colored border, sometimes few in number, sometimes covering the greater part of the surface, and giving rise on the face to great disfigurement and a feeling of stiffness and tension. The patches are evanescent, rapidly disappearing but only to give place to a new eruption. For the first day or two the disease is apt to be attended with a little fever, but this soon subsides, and after a variable

time, generally about a week, the eruption disappears, leaving no traces. In *U. exanida* there is no febrile movement, and the disease is frequently chronic, the eruption often appearing and disappearing several times a day, and frequently assuming the appearance of long wheals as if produced by a whip. *U. tuberosa* is the rarest and the most severe of the forms of nettle rash, in which the eruption is in the form of red swollen patches of the breadth of the hand, attended with an intolerable itching. The patches extend deeply into the skin, are numerous, and produce a very disagreeable feeling of swelling and stiffness. The rash commonly shows itself in the evening to disappear in the morning, leaving a sense of weakness and prostration. It occurs chiefly in habits impaired by excess, and its course is often tedious and intractable.—Nettle rash is most common in nervous persons with a delicate and irritable skin, and consequently in women and children. Its most frequent cause is some irritation of the digestive organs; with some persons the use of a particular article of diet is invariably followed by an eruption of nettle rash, the offending article varying greatly in different cases, and only to be detected by experience. There are some ordinary articles of diet, as mussels, crabs, several of the richer varieties of fish, &c., which act as true poisons in certain individuals, producing a violent eruption of *urticaria*. Here the symptoms are often excessively severe, the patient suffering from intense headache and giddiness, violent nausea and vomiting, colicky pains in the stomach and bowels, free purging, &c. Sometimes there are violent pains in the back and limbs, sometimes a total loss of sensation and motion. The febrile reaction is often severe, and the eruption is general, attended with great swelling and violent itching and tingling. In ordinary febrile *urticaria*, rest, attention to diet, a cooling regimen, and the use of the tepid bath, are all that is necessary. Occasionally an alkaline wash may be found useful in relieving the itching. *U. exanida* is an intractable complaint, and is best treated by strict regulation of the diet. In the severer forms of nettle rash produced by fish poisoning, &c., the rash is of but minor consequence; the poison should first be got rid of by stimulating emetics, and afterward the treatment must be conducted on general principles.

NETTLETON, ASAHEL, D.D., an American clergyman, born in North Killingworth, Conn., April 21, 1783, died May 16, 1844. He was graduated at Yale college in 1809, and entering at once upon the study of theology was licensed to preach in May, 1811, by the west association of New Haven co., and in 1817 was ordained as an evangelist by the south consociation of Litchfield co. He had studied with the view of becoming a missionary, but the effect produced by his preaching was so powerful that he was induced to postpone carrying out his intention, although he did not give it up en-

tirely until 1822, when his health failed. Immediately after being licensed he went to the E. part of Connecticut, bordering on Rhode Island, and visited several places where Davenport had labored during the religious excitement of 1740 and 1741, and which still showed the effect of his teachings. From 1812 to 1822 he preached revivals in 82 villages of Connecticut, among which were Derby, Danbury, Bloomfield, Chester, Bolton, Manchester, Salisbury, Waterbury, Rocky Hill, New Haven, Wethersfield, Farmington, Litchfield, and Tolland; in Massachusetts, in the towns of Pittsfield, Lenox, Lee, and Wilbraham; and in New York, at Saratoga, Ballston, Malta, Milton, Schenectady, and Nassau. In most of these places his ministrations were attended with the greatest success. He never completely regained his health after an attack in 1822 of typhus fever, from which for a long time he was not expected to recover. In the interval of quiet which his enfeebled constitution demanded, he published a volume of "Village Hymns" (New York, 1824), which had an extensive circulation. He resumed his active labors in 1824. In 1827 he went to Virginia for the sake of his health, and returning in 1829 preached in New England and New York until 1831. In the spring of that year he made a voyage to England, passing some time also in Scotland and Ireland, but his preaching did not satisfy the expectations that had been formed of it. Returning in 1832, he was shortly afterward appointed professor of pastoral duty in the newly organized theological seminary at East Windsor; and although he did not accept the office, he took up his residence in the place, and lectured occasionally to the students. Dr. Nettleton's sermons were chiefly extemporaneous, and often doctrinal, rarely addressing themselves to the imagination. In his character there was a vein of eccentricity, which perhaps hindered to no small extent his usefulness. In later life his opposition to the doctrinal views of the New Haven school of theology gave a decided coloring to all his intellectual efforts, although he did not participate publicly in the controversy.

NEUFCHÂTEL (Germ. *Neuenburg*), a W. canton of the Swiss confederation, consisting of the former principality of Neuchâtel and the county of Valengin or Valendia, bounded N. and N. E. by the canton of Bern, S. E. by Freyburg and Vand, S. by Vand, and W. and N. W. by France; greatest length 86 m., greatest breadth 18½ m.; area, 296 sq. m.; pop. in 1842, 59,000; in 1860, over 73,000. Several ridges of the Jura mountains traverse the canton. The lake of Neuchâtel, 28 m. long, 7 m. wide, and 400 feet deep, separates Neuchâtel from Freyburg and Vand, and is connected with the river Rhine by several smaller lakes and streams. Cattle, wine, fruit, hemp, flax, and grain are the principal agricultural products, but the grain crop is not sufficient to sustain the population. The raising of cattle is

the most important branch of agricultural industry. With the exception of 6,000 Roman Catholics, the people all belong to the Reformed church. The principal language is French, but the German is also spoken. Watch making, lace making, and cotton manufacture are the leading industrial pursuits. The constitution of the canton is democratic. Its revenue averages \$60,000, its contribution to the federal treasury less than \$5,000; its quota of men in the federal army is 1,662.—Neuchâtel belonged to Burgundy until A. D. 1082, when it became part of the German empire. After having been a fief of the counts of Freyburg and the margrave of Hochberg, it became a possession of the Longueville family, and was inherited from them by William III. of Orange, who ceded it to Prussia. It remained with Prussia as a principality with a separate government until 1806, when Napoleon compelled Prussia to cede it to Marshal Berthier. In 1814 Prussia regained possession of Neuchâtel, and procured its admission into the Swiss confederacy, it being the only canton with a monarchical constitution. In 1848 a revolutionary movement severed the connection with Prussia; and an attempt of the royalist party in 1857 to reinstate the Prussian authority having been frustrated, the independence of the canton was at last recognized by Prussia, May 26, 1857.—NEUCHÂTEL, the capital, is situated at the embouchure of the river Seyon into the lake of Neuchâtel; pop. 8,500. It contains many flourishing industrial establishments, two hospitals founded by benevolent citizens at a cost of \$80,000 and \$250,000 respectively, a college, an orphan asylum, and other richly endowed institutions of public charity.

NEUHOF, THEODOR VON, baron, a German adventurer, born in 1690, died in London, Dec. 11, 1756. He was the son of a Westphalian nobleman, studied in Münster and Cologne, was compelled to leave the latter city on account of having killed in a duel a young man of high family, and obtained through the influence of the Spanish minister at the Hague a lieutenancy in the Spanish army in Africa. He fell into the hands of the Moors, and is believed to have been employed during 18 years as interpreter by the dey of Algiers. In 1785 he repaired at the head of two regiments, chiefly composed of Tunisians and Algerians, to Corsica to assist that island in its struggle against Genoa. Baron Neuhoof ingratiated himself so much with the Corsicans that they elected him as their king, April 15, 1786, under the name of Theodore I. He succeeded in securing the alliance of the Netherlands; but the French coming to the assistance of the Genoese in 1788, the Corsicans were again subdued, and Neuhoof was compelled to resort to flight. In 1741, when the French garrison left the island, he endeavored to regain his power, but was not successful, and spent the remaining part of his life in England, where a subscription,

headed by Walpole, saved him from his creditors. His monument bears the inscription: "Fortune gave him a kingdom, and in his old age withheld bread from him."—There are various other versions of Neuhoof's life and adventures, but the above is that most generally credited by his own countrymen. He left a son who assumed the name of Col. Frederic, was in the duke of Württemberg's service, published two historical works on Corsica, and shot himself in Westminster abbey, Feb. 1, 1796.

NEUILLY, a town of France, in the department of Seine, on the right bank of the river Seine, $1\frac{1}{2}$ m. N. W. from Paris; pop. in 1856, 28,147. The river is here crossed by a handsome bridge of 5 arches, each 120 feet wide. The park, which extended for some distance along the Seine, was a favorite resort of the Parisians, but has been cut up into villa sites. The principal object of interest is however the ruined palace, once the residence of Louis Philippe. It was destroyed by the populace, Feb. 25, 1848, with the exception of one wing. Louis Philippe adopted the title of count of Neuilly during his exile.

NEUKOMM, SIGISMUND, chevalier, a German composer, born in Salzburg, July 10, 1778, died in Bonn in April, 1857. He was educated by his kinsmen Michael and Joseph Haydn, and in 1829, after a busy career in various parts of the world, accompanied Prince Talleyrand to England, where he passed the greater part of his remaining life. He excelled as a composer of sacred music, and his oratorios of "Mount Sinai," produced at the Derby musical festival of 1831, and "David," at that of Birmingham in 1834, are impressive and popular works. He produced in addition to these an immense number of cantatas, songs, psalms, voluntaries for the organ, symphonies, quartets, sonatas, &c., his compositions, both vocal and instrumental, amounting to nearly 800. In the latter part of his life he was afflicted with partial blindness; but until his retirement to Bonn, a few years previous to his death, he was an indefatigable traveller over almost every part of Europe.

NEUMANN, KARL FRIEDRICH, a German orientalist, born in Reichmannsdorf, near Bamberg, Dec. 22, 1798. He is of Jewish extraction, and at an early age entered a counting house in Frankfort-on-the-Main, whence he repaired to the university of Heidelberg. He subsequently studied at Munich and Göttingen, and in 1822 was appointed professor of history at Spire, but was compelled on account of his liberal views to retire. He next devoted several years to the study of the oriental languages, particularly the Chinese and Armenian, and in 1829-'30 visited China to make a collection of works by native authors. He returned to Europe with 10,000 volumes, of which 2,500 were placed in the royal library of Berlin. In 1831 he was appointed professor at Munich, where his lectures on the Armenian and Chinese languages and literature attracted

much attention; but his political sympathies again involved him in trouble, and for too open an expression of his democratic views in 1848 he was in 1852 deprived of his professorship. Among his numerous works are: *Mémoires sur la vie et les ouvrages de David*, an Armenian philosopher of the 5th century (Paris, 1829); "History of Vartan" and "Vabram's Chronicle of the Armenian Kingdom in Cilicia" (London, 1830), both translated from the Armenian into English; *Lehrsaal der Mittelreich* (Munich, 1836); "History of the Anglo-Chinese War" (Leipsic, 1846); "The People of Southern Russia in their Historic Developments;" and translations from the Chinese and other languages.

NEURALGIA (Gr. *νευρον*, nerve, and *αλγος*, pain), an affection of which pain is the essential and characteristic feature, and which depends on some disease affecting the structure or function of the nerves or of their centres. The varieties of neuralgia are very numerous. Some are distinguished according to the nerve affected; as neuralgia of the trifacial nerve, commonly called tic douloureux; sciatica, or neuralgia of the sciatic nerve; intercostal neuralgia, affecting the intercostal nerves, &c. Other varieties are described according to the locality which is the seat of pain; as gastralgia, or pain in the region of the stomach; nephralgia, or pain in the region of the kidneys, &c. Other varieties again are indicated by the causes which produce them; as miasmatic neuralgia, the neuralgia caused by marsh miasm; saturnine neuralgia, the neuralgia produced by the poison of lead, &c. The causes of neuralgia may be classified as constitutional and local. The principal constitutional causes are: 1, the impoverished condition of the blood, resulting either from hæmorrhage or the exhausting effects of disease, such as fevers, chlorosis, &c.; 2, the miasm of paludial regions; 3, the *materia morbi* of rheumatism; 4, the virus of syphilis; 5, the circulation in the blood of poisonous secretions, such as urea and bile; 6, the poisonous effects of lead, and probably of some of the other metals; 7, the functional derangement of the nervous system in the disease known as hysteria. The local causes are: 1, inflammation of the delicate fibrous sheath which envelopes the nerves, called the neurolemma; 2, the development of tumors near the origin, or along the course, or amid the ramifications of the nerves, as neuromata, fibrous tumors growing from the nerve sheath, and cancerous, aneurismal, cartilaginous, or bony tumors, so situated as to stretch or press upon the nerves; 3, the bulbous expansion of the extremities of divided nerves, occurring after amputation, and causing painful stumps; 4, the pinching of nerves in the cicatrices or scars of lacerated wounds.—The successful treatment of a neuralgia depends of course on a correct appreciation of the causes that produce it. Where it arises from constitutional causes, it is generally amenable to treatment. The neuralgia that depends on an impoverished state of

the blood yields almost invariably to iron tonics, good diet, and outdoor exercise; that which arises from the effects of paludial poison disappears rapidly under the use of quinine; neuralgia of rheumatic origin is ordinarily controlled by the preparations of colchicum, the alkalis, alkaline and sulphur baths, &c.; while the neuralgia caused by lead poison has its specific antidote in the iodide of potassium, a remedy which is useful also in the neuralgia of syphilitic origin. The neuralgia which occurs in hysteria yields, like most of the protean phenomena of that disease, to the mineral tonics, electricity, shower baths, and exercise. Before speaking of the treatment of the forms of neuralgia caused by local disease, it is to be remarked that the seat of pain in these cases does not always correspond with the location of the cause of irritation. For instance, a tumor within the cranium may produce pain at the extremity of the sensitive nerves, near the origin of which it is located; or pressure in the course of a nerve may cause pain in its ultimate ramifications. Where neuralgia is caused by irritation near the origin of the nerves, in the brain or spinal cord, its radical cure is generally impracticable; where it depends on the pressure of tumors that can be removed, the pain will generally disappear with the removal of the cause. In inflammation of the nerve sheath, local counter-irritation, by cups, blisters, issues, setons, &c., usually gives relief, and generally effects a cure. The neuralgia of painful stumps and painful scars, and of obstinate cases of inflammation of the neurolemma, requires surgical interference, such as reamputation, removal of the cicatrix, or excision of a portion of the diseased nerve. Temporary relief may be given in all forms of neuralgia by the administration of powerful anodynes. Those most commonly used are morphine, the active principle of opium, and aconitine, the active principle of the *aconitum napellus* or monkshood. These may be used internally or externally. A solution of morphine injected into the areolar tissue beneath the skin, near the seat of the neuralgia, gives more prompt relief than when given by the stomach. Aconitine is generally used externally, in ointments, in the proportion of $\frac{1}{4}$ or $\frac{1}{2}$ grain to the drachm of ointment; it gives almost instantaneous relief.

NEUROPTERA (Gr. *νευρον*, nerve, and *πτερον*, wing), an order of insects characterized by powerful jaws, 4 reticulated, membranous, naked wings, and the absence of sting or piercer. They include the dragon and May flies, ant lion, white ant, and similar predaceous insects, which undergo a complete or partial metamorphosis. The larvæ are 6-legged, voracious and carnivorous, living in the water, on trees, or in the ground. Only the white ants and the wood ticks are injurious to vegetation; the others are rather beneficial to man by devouring aquatic and flying insects, plant lice, and similar pests. They are generally of elegant

proportions, often prettily marked, and possess great powers of flight. Kirby separated the May or caddis flies (*phryganeada*), and formed of them his order *trichoptera*. It is commonly believed that the ravages of white ants and their congeners are confined to tropical regions and to dead or decaying vegetation; but recently at Salem, Mass., a white ant, allied to the genus *termes*, has been discovered making its mines and galleries, attacking and destroying with its colonies the roots of grape vines in greenhouses, and making their chambers even in the living wood.

NEUSIEDLER LAKE (Hung. *Fertő*), after Balaton the largest lake of Hungary, situated near the Austrian frontier on the confines of the counties of Oedenburg (Soprony) and Wieselburg (Mosony); length about 28 m., breadth 7 m., depth 9 to 18 feet. The reedy banks of the lake shelter innumerable water fowl. The E. side is marshy, adjoining the extensive marshes of Hânság. In times of sudden inundations the overflowing waters are carried through an artificial canal into the river Rabnitz. The W. bank is surrounded by beautiful vine-clad hills, at the foot of which the town of Rust is situated. Other neighboring towns also W. of the lake are Oedenburg and Eisenstadt.

NEUSTRIA, the name of the western division of the Frankish empire, under the Merovingians and Carolingians, from the partition of the provinces by the sons of Clovis in 511 to the beginning of the 10th century. In the earlier part of that period Neustria extended from the Meuse, which formed its boundary toward Austrasia, the eastern division, to the ocean and the Loire, which separated it from Aquitania. The principal towns were Soissons, Paris, Orleans, and Tours. In later times it was restricted to the territories lying between the Seine and the Loire. The name disappeared when the maritime territory was ceded to the Normans, receiving the name of Normandy. (See FRANCE, vol. vii. p. 668.)

NEUTRALITY, in international law, the indifferent and impartial posture maintained by one nation with regard to others which are at war. "The neutral state," says Klüber, "is neither judge nor party." It may be the common friend of both belligerents, but may not favor either. The character of neutrality is generally impressed upon a nation only by the event of war, while in time of peace it may conclude offensive and defensive alliances, and in all respects arrange at its pleasure its relations with other states. Yet there may be what is called a permanent neutrality. By the public law of Europe, Switzerland and Belgium are to remain always neutral and independent of any complications which may in the future arise among the other European powers. These states, it is evident, cannot even in peace enter into any compacts or engagements which would be inconsistent with complete neutrality in case of war.—It is not a violation of neutral-

ity to furnish one only of two hostile parties with ammunition or other war supplies, provided this be done in accordance with previous treaty stipulations. Thus, by the treaty of 1788 with the United States, France secured the exclusive privilege of asylum in American ports for her privateers and their prizes. But in this case, as usually, such a qualification of neutrality, though clearly sanctioned by the law of nations, did not fail to provoke complaint and protest from the less favored power. It is not consistent with a neutral character to concede to one belligerent, to the exclusion of others, the liberty of raising land or sea forces within the neutral territory. This privilege the United States refuse to all belligerents alike, and the prohibition is declared by a permanent act of congress. The subject of foreign enlistments in neutral territory, and the doctrine maintained upon the point by the U. S. government, are clearly set forth in the official opinion of Attorney-General Cushing of Aug. 9, 1855.—The perfect inviolability of its territory is the clearest if not the chief among the rights of a neutral state. A belligerent therefore cannot attack his enemy on neutral ground, and, in spite of a condemnation by a prize court of the captor, the neutral power will restore to its owner property captured within its jurisdiction. The neutral may refuse to all belligerents the privilege of passage over its domain, or must grant it, if at all, to all alike. It may forbid the entrance of war vessels and their prizes into its ports, although, in the absence of positive prohibition, the liberty to enter is implied. Our government has uniformly conceded this favor to the public ships of the hostile powers, without their prizes. To admit the entrance and sale of these in neutral ports is a favor which, in the opinion of eminent authorities, is hardly consistent with perfect neutrality, or with the dictates of true policy. As an illustration of the latest practice in this respect, it may be added, that in the late Russian war, Sweden and Norway and Denmark, adopting the same rules of neutrality, admitted into their ports the ships of war and of commerce of the belligerent parties, and accorded to them the facility of supplying themselves with all necessary stores and provisions not contraband of war, but forbade, except in cases of distress, the entrance, condemnation, or sale of any prize in any of the harbors of these kingdoms.—Whether the neutral can claim this territorial immunity for its ships, whether in other words its flag shall protect the whole ship and cargo from the assertion of belligerent rights, has been a much vexed question in international law. The treaties concluded at Utrecht in 1713 had embodied the principle that the character of the vessel should determine that of its cargo; and though the same principle had been introduced into frequent conventions, based upon these treaties, to which England had been a party, yet this power always refused to admit that express stipulations of this nature

could change what it called the common law of nations in the premises. Except, therefore, when it was bound by special compacts, England has steadily maintained the integrity of the rule that enemy's goods on board a neutral ship are good prize of war. In 1781 the Baltic code of neutrality was first proclaimed by Catharine II. of Russia. One of its most prominent articles asserted the principle of the treaties of Utrecht, namely, that free ships should make free goods. The principal powers of Europe, excepting only England, acceded to the Russian rules of neutrality. The single influence of England, however, against the code was too great to be withstood, and it was abandoned in 1787. An attempt to revive it in 1801 was equally unsuccessful, and for the same reason. In its general jurisprudence the United States has, almost of necessity, adopted the English rule. But in its treaties, and particularly in those with American powers, it has generally inserted the more liberal principle that neutral ships shall make free goods. Since 1786 England had generally asserted her belligerent rights, until at the commencement of the Russian war, by a common declaration with her ally France, promulgated in April, 1854, she announced that for the present she "waived her right of seizing enemy property laden on board neutral vessels, unless it were contraband of war." At the conclusion of the war England gave a more formal assent to the principle which she had so long opposed; for the declaration which was signed at the congress of Paris in 1856 by the plenipotentiaries of all the great powers, contained the provision that the neutral flag shall cover enemy goods, with the exception of those contraband of war, and it may be supposed has fixed the maxim in the law of nations. The rule usually coupled with that just referred to, though the two have really no connection, namely, that neutral goods, except contraband, are not liable to capture though laden in enemy ships, is also included in the declaration of the congress of Paris. It was formerly rejected by France, but other nations have generally observed it.—Subject only to slight and reasonable restrictions, the neutral may carry on its commerce with the hostile powers. But plainly it must not furnish either with war supplies, nor indeed with any material which can directly contribute to the prosecution of hostilities. In the familiar phrase of the international law, its ships must not carry contraband. Further, they must neither break blockades, nor carry despatches for either party, nor in any other mode render direct assistance in the war. Finally, neutral ships must be always ready to prove themselves that which they profess to be, and must therefore be provided with papers sufficient to prove their nationality, and must submit to a reasonable exercise of the right of visitation. It is not possible to define contraband specifically, that is, to declare what particular articles will be so regarded in time

of war. There can be no doubt, however, respecting things which can be used only in war, or respecting materials which are peculiarly fitted by their nature for warlike uses. On the other hand, things which cannot be employed in war are, it is equally certain, not contraband. But it is difficult to determine the character of articles which are *ancipitis usus*, of a double or indifferent nature, and serviceable as well in peace as in war, such as money, provisions, ships and materials for ships, and naval stores. The decision will always be influenced by many considerations, as by the state and nature of the war, or by the highly probable destination of goods to a military use. Thus provisions, which *prima facie* are not contraband, will certainly be declared so when they are destined to a besieged town or blockaded port. The character of the port to which goods are bound may also be of consequence—whether, that is to say, it be a port of merely naval equipment, or one of general commerce. The changes which science has made in the needs and modes of warfare are also to be regarded, as well as the consideration whether the goods alleged to be contraband are or are not the produce of the country which exports them. Carrying official communications for a belligerent upon the public affairs of his state is a flagrant violation of neutrality. But to carry despatches from the enemy to his ambassador or consul in a neutral country is, generally speaking, no ground for condemnation, for the legal presumption is that the communication has reference to the commercial relations of the belligerent and the neutral. It seems to be the better opinion that the contraband character of the ship or goods terminates with that passage in which the forbidden trade is intended or done, and does not affect the whole voyage. The owner of the contraband loses all, even the innocent goods which he has laden in the ship. Other shippers forfeit nothing. This doctrine of contraband implies rather necessarily the belligerent's right to search neutral ships for such articles as may contribute to the comfort and strength of the enemy. The law of nations has been in this respect that in time of war search may be made for contraband and for enemy's goods. The late modification of the former practice, by which, as we have already seen, the goods of the enemy in neutral ships are now exempted from seizure, must tend, it would seem, to reduce the application of the law of search to the case of contraband alone. Some powers have defeated or hoped to defeat the right of search for contraband goods by forbidding their subjects to carry them; and sometimes treaties have provided that, in the case of ships under convoy, the declaration of the commander should suffice to exempt the ships in his charge from search.—A further restriction in force on the commerce of the neutral consists in his incapacity to trade to blockaded ports. To constitute a violation of blockade there must be

first an actual blockade by a force sufficient to maintain the same; then there must have been proper notification of it; with these must concur some act of violation, either by going in or coming out with a cargo laden after the commencement of the blockade. Sir William Scott once held that a temporary absence of the blockading squadron, from being driven off by a storm or other accident, did not suspend the operation of the blockade. The French publicists controvert this doctrine, as unwarranted by the general principles of international law. But the law as Sir William Scott declared it is probably at present the law of England. The English and French declarations, however, of March, 1854, speak of "effective blockades, which may be established with adequate forces." Some exception has been taken in the United States to the rule which forbids the departure of a vessel laden after the blockade was known. In a communication to Mr. Buchanan, U. S. minister in London, in 1854, Mr. Marcy urges that, having visited the port in the common freedom of trade, the neutral vessel ought to be allowed to depart with a cargo, without regard to the time when it was received on board. This relaxation of the law of blockade will be hardly yet admitted in the general practice of nations; but, especially in our treaties with the Central and South American republics, it has assumed the form of familiar stipulation. The treaty with Guatemala provides, for example, that no vessel of either of the contracting parties which shall have entered into any port or place of one power, before the same was actually besieged, blockaded, or invested by the other, shall be restrained from quitting such place with her cargo, nor, if found therein after the reduction and surrender, shall such vessel or her cargo be liable to confiscation, but shall be restored to the owners thereof.—The principles of the international law of neutrality assume a peculiar significance in the law of marine insurance. In marine policies the ownership of the property is usually the subject of express warranty, and underwriters are thus informed of its liability to or freedom from war risks. The neutrality itself may be sometimes expressly warranted. In these cases the warranty is construed to mean, first, that the ship or cargo is actually owned by citizens of a country not at war when the risk begins, and secondly, that with the property there shall go all those usual documents and precautions which prove the neutrality and protect it from belligerent risks. The bill of sale of the ship, the sea letter or customary certificate of nationality, the register of the vessel, the charter party, shipping papers, the log book, and in general all the documents which usually state the national character, and especially the flag, must conform to the warranted neutrality of the ship. The law holds, too, that if a vessel exhibit only false papers when she is captured, there is a breach of the warranty, though she have

on board the proper papers of her nation, and have the right to carry false papers, because she must not only have the proper documents, but must use them at a proper time and in a proper way. Yet it seems that simulated or false papers may not only be carried when leave is expressly given, but when a usage exists to carry them, which is or should be known to the insurer. The warranty of the neutrality of a ship is broken if a belligerent own any part of it. In regard to goods the rule is different, and the warranty is held to extend only to the interest of the insured, and is not broken by the fact that a part of the cargo not insured is not neutral. But when the interest insured covers the whole cargo, the law will regard the real ownership; and therefore property held by a neutral by a legal title indeed, but for the benefit of and in trust for a belligerent, is belligerent property. If neutral goods are shipped in time of peace to a consignee who has not ordered them, so that the property would not vest in him till the goods were received, in case of capture they are considered as the property of the consignor. But if they are shipped by a neutral after the war begins, and under a contract made during peace but in contemplation of war, and to be at the risk of the sendee until delivery, they are put on the same footing as if the contract were made during war. If a subject of a belligerent power ship goods to a neutral which have not been ordered by him, so that the belligerent retains control over them, they are considered as his property. The mere right of the belligerent seller to stop goods *in transitu* on the insolvency of the vendee is not such an interest as would make the goods belligerent. The warranty of neutrality requires such trade, conduct, and course of transaction as shall be in conformity and adaptation to this warranty. Therefore, if the neutral interests or property are indistinguishably mixed up with belligerent interests or property, they become themselves liable to all the incidents and effects of a belligerent character. So resistance of a search when rightfully demanded, an attempt at rescue, seeking belligerent protection or receiving it, are all breaches of the warranty of neutrality, because they belong to the conduct of a belligerent. It is a sufficient compliance with the warranty, that a vessel is neutral according to the law of nations; and for a condemnation for breach of ordinances which are contrary to the law of nations, the underwriters are still liable.

NEUVILLE, HYDE DE. See HYDE DE NEUVILLE.

NEUWIED, a German town, capital of the principality of Wied (formerly Neuwied), now mediatized and attached to Prussia, situated in the district of Coblenz, on the right bank of the Rhine; pop. about 7,000. It is a pleasant and well built town, founded at the beginning of the 18th century. By the liberality of its princes, industrious persons of different

religious creeds were attracted to the place, and established there manufactures of woollen and cotton goods and other articles, which have given to it its present prosperity. The palace possesses a collection of Roman antiquities, chiefly from the buried Roman city Victoria discovered near Neuwied in 1791. In the museum of natural history are the Brazilian and North American collections of Prince Maximilian. Neuwied possesses a normal school, and is particularly known abroad by its settlement of Moravians (*Herrnhuter*), who have their church, schools, workshops, &c., in a distinct part of the town.

NEUWIED, or WIED, MAXIMILIAN ALEXANDER PHILIPP, prince of, a German naturalist and traveller, born Sept. 28, 1782. His mother, the countess of Wittgenstein-Berleburg, was a woman of remarkable attainments, and encouraged his love for travel, which led him, after rising to the rank of major-general in the Prussian army, to explore Brazil from 1815 to 1817. The result of his observations is embodied in his *Reise nach Brasilien* (2 vols., Frankfurt, 1819-'20), and in his *Abbildungen zur Naturgeschichte Brasiliens* (Weimar, 1822-'31) and *Beiträge zur Naturgeschichte Brasiliens* (4 vols., Weimar, 1824-'33). Subsequently he travelled in the United States, and wrote *Reise durch Nordamerika*, with 81 plates (2 vols., Coblenz, 1838-'43; English version, London, 1843), a work which is as much valued for the beauty of its illustrations as for its contributions to American ethnography. He is the uncle of the present Prince Wilhelm Hermann of Wied.

NEVA, a river of Russia, flowing from the S. W. extremity of Lake Ladoga, first S. W., then N. W., and ultimately through the city of St. Petersburg, discharging itself by many mouths into the gulf of Finland. Its entire course is not more than 40 m., but it is very wide, has an average depth of from 2 to 3 fathoms, and is of great commercial importance. It is liable, particularly at the breaking up of the ice in April, to sudden inundations, often most disastrous to St. Petersburg, which is built on the islands formed by its branches.

NEVADA, a N. E. co. of Cal., bordering on Utah, and drained by Middle and South Yuba rivers; area estimated at 1,000 sq. m.; pop. in 1852, 21,865. The surface is generally mountainous, especially toward the E., which is traversed by the Sierra Nevada range. One half of the entire area is estimated to be occupied by mineral lands. Mining is the principal industry, and agriculture receives little attention. The county contains several of the richest and most productive quartz leads in the state, and the placer diggings are not surpassed by any other. The number of quartz mills in operation in 1858 was 32, of which 21 were propelled by steam; number of arastras 36; cost of machinery \$500,000. The agricultural products in the same year were 112,000 bushels of wheat, 260,000 of barley, and 56,000 of oats. There were 3 grist mills, 42 saw mills,

2 founderies, 8 tanneries, and 7 breweries. Value of taxable property, \$4,301,998. Capital, Nevada.

NEVERS, a town of France, capital of the department of Nièvre, on the right bank of the Loire, 188 m. by railway S. E. from Paris; pop. in 1856, 16,082. Anchors, machinery, &c., are manufactured. Cæsar mentions the town in his "Commentaries" under the name of Noviodunum. In the middle ages it was the capital of a duchy, the last duke of which sold it to the crown of France in 1665.

NEVIN, JOHN WILLIAMSON, D.D., an American theologian, born in Franklin co., Penn., Feb. 20, 1808. He was graduated at Union college, New York, in 1821, studied theology for three years in the theological seminary at Princeton, N. J., and continued there two years afterward as assistant teacher in the place of Professor Hodge, then absent in Europe. During this time he wrote "Biblical Antiquities" (2 vols., 1828). He was licensed to preach by the presbytery of Carlisle in 1828. Toward the close of 1829 he was called to the western theological seminary of the Presbyterian church in Alleghany City, where he continued as assistant teacher, and afterward as professor of Hebrew and biblical literature, for 10 years; and in the meanwhile he was ordained. He also edited in 1833 and 1834 "The Friend," a weekly literary journal published under the auspices of the young men's society of Pittsburg and its vicinity. In 1840 he removed to Mercersburg, Penn., in obedience to a call from the synod of the German Reformed church inviting him to take charge of its theological seminary, in connection with Dr. F. A. Rauch, who was at the same time president of Marshall college in the same place. The death of Dr. Rauch, March 2, 1841, left him the sole charge of the theological seminary, and the presidency of the college, till 1844, when Dr. Philip Schaff was called as his colleague in the seminary. In 1843 he published "The Anxious Bench," which calls in question the propriety of certain means and measures then extensively employed in the service of religious revivals. This work furnished occasion for much controversy. It was enlarged in a subsequent edition, and also translated into German. The same year he published a translation of Dr. Schaff's "Principle of Protestantism," with an introduction, and a sermon on "Catholic Unity." In 1846 he published "The Mystical Presence," a vindication of the reformed doctrine of the holy eucharist; in 1847, the "History and Genius of the Heidelberg Catechism;" in 1848, "Anti-christ, or the Spirit of Sect and Schism." From Jan. 1849, to Jan. 1853, he edited the "Mercersburg Review," published by the alumni association of Marshall college, which is still continued, and to which he has been up to this time (1860) a prominent contributor. At the close of 1851 he resigned his situation as professor in the theological seminary, continuing to act as president of Marshall college until

its union with Franklin college at Lancaster, Penn., in 1853, and its consequent removal to that place. He was offered the presidency of the college in its new form, but declined it. He now lives in literary retirement near Lancaster.—It was during Dr. Nevin's connection with the theological and literary institutions at Mercersburg and the "Mercersburg Review," that the movement began and was carried forward which has developed itself into what is called the "Mercersburg system of theology." Of this movement Dr. Nevin was the originator and exponent. It seemed to grow into shape without calculation or plan. It owes its existence properly not to any spirit of philosophical speculation, as has been sometimes imagined, but to an active interest in practical Christianity. Historically it may be regarded as having commenced with the publication of "The Anxious Bench" in 1843. Then came the sermon on "Church Unity," preached by Dr. Nevin at the opening of the triennial convention of the Reformed Dutch and German Reformed churches at Harrisburg, Penn., in 1844; a discourse sanctioned by the official representatives of both churches at the time, the positions of which, however, on the subject of the mystical union and in opposition to the sect system, were felt by many afterward to involve a dangerous tendency. Dr. Schaff's "Principle of Protestantism" brought out the tendency, in the apprehension of such persons, under still more alarming proportions. This was followed by the "Mystical Presence," with a translation of Dr. Ullmann's masterly tract on "The Distinctive Character of Christianity," prefixed in the form of a preliminary essay. The work was a vindication at large of the old Calvinistic doctrine of the Lord's supper, conveying against the general Protestantism of the time a charge of wholesale defection from the Protestant sacramental faith of the 16th century. The tract "Antichrist" was an assault upon the sect system, as being in full antagonism to the true idea of the church, and such a heresy as draws after it virtually in the end a Gnostic denial of the proper mystery of the incarnation itself. As the occasions of theological discussion were thus multiplied, it was felt necessary to establish a special organ for carrying it forward; and thus originated the "Mercersburg Review," the pages of which for some years form a sort of progressive picture of the system to whose exposition and defence it has been devoted from the first.—The cardinal principle of the Mercersburg system is the fact of the incarnation. This, viewed not as a doctrine or speculation, but as a real transaction of God in the world, is regarded as being necessarily itself the sphere of Christianity, the sum and substance of the whole Christian redemption. Christ saves the world, not ultimately by what he teaches, or by what he does, but by what he is in the constitution of his person. His person in its relations to the world carries in it the power of

victory over sin, death, and hell, the force thus of a real atonement or reconciliation between God and man, the triumph of a glorious resurrection from the dead, and all the consequences for faith which are attributed to this in the Apostles' Creed. In the most literal sense accordingly Christ is here held to be "the way, the truth, and the life," "the resurrection and the life," the principle of "life and immortality," the "light" of the world, its "righteousness," and its "peace." The "grace which bringeth salvation," in this view, is of course always a real effluence from the new order of existence, which has thus been called into being by the exaltation of the Word made flesh at the right hand of God. It must be supernatural as well as natural, and the organs and agencies by which it works must in the nature of the case carry with them objectively something of the same character and force. In this way the church is an object of faith; the presence of a new creation in the old world of nature; the body of Christ, through which as a medium and organ he reveals himself and works till the end of time. It mediates with supernatural office instrumentally between Christ and his people. Its ministers hold a divine power from him by apostolic succession. Its sacraments are not signs merely, but seals of the grace they represent. Baptism is for the remission of sins. The eucharist includes the real presence of Christ's whole glorified life, in a mystery, by the power of the Holy Ghost. The idea of the church, when it is thus held as an object of faith, involves necessarily the attributes which were always ascribed to it in the beginning, unity, sanctity, catholicity, and apostolicity. The spirit of sect, as it cleaves to Protestantism at the present time, is a very great evil, which is of itself sufficient to show that if Protestantism had any historical justification in the beginning, its mission thus far has been only half fulfilled, and that it can be rationally approved only as it is taken to be an intermediate preparation for some higher and better form of Christianity hereafter. The distinguishing character of the Mercersburg theology, in one word, is its Christological interest, its way of looking at all things through the person of the crucified and risen Saviour. This, as the world now stands, embraces necessarily all that enters into the conception of the church question, which this system holds to be the great problem for the Christianity of the present time.

NEVIS, an island of the British West Indies, in the Leeward group, 2 m. from the S. E. extremity of St. Christopher, in lat. 17° 14' N., long. 63° 3' W.; area, 20 sq. m.; pop. 10,200. With the exception of a narrow circle of fertile land bordering upon the coast, the whole island may be said to consist of a single mountain 2,500 feet high, the upper parts of which are not susceptible of cultivation. The arable lands, comprising in all only 6,000 acres, are well cultivated. Sugar is the staple, and with molasses and rum forms the bulk of the exports. The

exports in 1855 amounted to £38,977, and the imports to £19,728. The island is subject to a lieutenant-governor, who is assisted by an executive council and a house of assembly. Charlestown, on the S. W. coast, is the capital and principal town, and has a good roadstead. Nevis was colonized by English emigrants from St. Christopher in 1628, was taken by the French in 1706, and restored by the peace of Utrecht, and was taken by them again in 1782, but restored by the peace of 1783. It was the birth-place of Alexander Hamilton.

NEW ALBANY, a city and the capital of Floyd co., Ind., on the Ohio river opposite Portland, Ky., 1 m. below the falls, 8 m. below Louisville, 136 m. below Cincinnati, and 110 m. S. by E. from Indianapolis; pop. in 1860, 15,000. It is built on an elevated bank which is seldom reached by the overflow. It is well laid out, with wide paved streets, the whole length of which, with lanes and alleys, amounts to 22 miles, is supplied with good water, and lighted with gas. There are commodious wharfs capable of accommodating the largest steamers, and the shipping business is constantly increasing. Steamboat building is an important branch of industry, and there are now 5 ship yards and 8 large foundries in operation. The city contains a number of wholesale establishments in various departments of merchandise, and has an active trade. There are 22 churches, viz.: 2 Baptist, 1 Christian, 1 Disciples', 1 Episcopal, 1 Lutheran, 8 Methodist, 4 Presbyterian, 2 Roman Catholic, 1 United Brethren, and 1 Universalist. The public school system is very efficient and thorough, and occupies for its various departments 5 school buildings. The city has a number of private educational institutions, and is the seat of the Indiana Asbury college and the New Albany collegiate institute. It is a terminus of the Louisville, New Albany, and Chicago railroad.

NEW BEDFORD, a city and port of entry, and one of the capitals of Bristol co., Mass., on Buzzard's bay, in lat. 41° 38' N., long. 70° 55' W., 55 m. S. E. from Boston; pop. in 1860, 22,524. The municipal limits include an area about 11 m. in length by 2 in width; the city proper, built along the W. side of the Accushnet river, is about 2 m. in length by 1 in width. The principal business is the whale fishery, which was pursued here as early as 1755. In 1765, 4 vessels were engaged in it, and at the revolution from 50 to 60, most of which were captured during the war. The business subsequently revived, but was again prostrated by the war of 1812; and it was not until 1818 that the impulse was given which has resulted in making New Bedford the centre of the whale fishery in the United States. The number of vessels in the district employed in the fisheries and foreign and domestic trade on Jan. 1, 1860, was 547, measuring 151,473 tons. Of this number 399 vessels (being 70 per cent. of the whole number in the United States engaged in this business), measuring 129,576 tons, were

employed in the whale fishery, 301 of which, measuring 103,564 tons, belonged to the port of New Bedford. The imports of the products of the whale fishery into the district in 1859, and their value, were as follows: 2,286,488 galls. sperm oil, value \$2,875,468; 4,715,583 galls. whale oil, \$2,046,553; 2,010,882 lbs. whalebone, \$1,290,119; value of other marine productions, \$16,807. The other imports amounted to \$127,501; exports, \$58,487; amount of duties collected, \$11,126; number of entries, 282; of clearances, 178. There are numerous manufacturing establishments, of which the principal are the Wamsutta cotton mills, established in 1846, with a capital of \$600,000, running 81,500 spindles, employing 550 hands, and manufacturing in 1859 \$544,786 worth of goods; the New Bedford gas light company, incorporated in 1850; the Gosnold mills for the manufacture of hoop iron; 13 oil and candle works, 4 soap factories, 2 flouring mills, a cordage factory, an iron foundry, and manufactories of screws, rivets, paper hangings, Prussian blue, and kerosene oil. There are 4 banks, with an aggregate capital of \$2,400,000; 2 savings banks, with deposits in 1859 to the amount of \$2,438,567; 1 fire and 4 marine insurance companies, 2 daily and 8 weekly newspapers, and a weekly shipping list. There are 24 churches, viz.: 4 Baptist, 4 Christian, 5 Congregational, 1 Episcopal, 2 Friends', 6 Methodist, 1 Roman Catholic, and 1 Universalist. Among the charitable institutions are a port society, which supports a Bethel for seamen; a domestic missionary society, maintaining 4 free chapels; and an orphans' home with about 30 inmates. There are 3 public cemeteries, and provision has been made for a 4th. The New Bedford social library was established in 1808. In 1852 it was merged in a free public library, maintained by the city. In 1857 a handsome library building, costing \$45,000, was completed. The library now (1860) contains 13,500 volumes. A lyceum was established in 1828, which is still in a flourishing condition. There are 41 public and several excellent private schools, among which is the Friends' academy, established in 1810. The principal public buildings are the city hall, a handsome Doric structure, which cost \$60,000, the Unitarian and the north Congregational churches, the custom house, an almshouse capable of accommodating 400 inmates, the public library, and the house of correction. Most of these are built of native granite. New Bedford is also noted for the elegance of its private residences. The national government is constructing an extensive fortification on Clarke's point at the S. end of the city. A bridge over 4,000 feet long connects New Bedford and Fairhaven. Two lines of screw steamers run to New York, and a steamer to Martha's Vineyard and Nantucket. Communication is had with Boston by two railroads, the New Bedford and Taunton, and the Fairhaven branch. The valuation of real estate in 1859 was \$9,718,600, and of personal

property \$15,905,000, making it the wealthiest community in the United States in proportion to the number of inhabitants.—New Bedford was set off from the town of Dartmouth in 1787, and received a city charter in 1847.

NEW BRITAIN, a post borough and township of Hartford co., Conn., 10 m. S. from Hartford, on the Providence and Fishkill railroad; pop. in 1860 about 5,000. It was set off from the town of Berlin in 1850, and has since grown with great rapidity. Among its manufactures, which are very numerous and of great variety, there are extensive establishments for the making of stockinet goods, bank and safe locks, jewelry, hooks and eyes, cabinet hardware, harness trimmings, rules, plumbs and levels, and one for the manufacture of locks, house trimmings, and general hardware, which is the largest and most complete establishment of the kind in the United States. The borough contains 6 churches (1 Baptist, 2 Congregational, 1 Episcopal, 1 Methodist, and 1 Roman Catholic), and the state normal school. (See *COMMERCE*, vol. v. p. 618.) It is lighted with gas, and an ample supply of water is obtained from a reservoir of 175 acres, at an elevation of 200 feet, giving a head sufficient for all fire purposes, entirely superseding the use of fire engines, and throwing a jet from the fountain on the public square to the height of 140 feet. The entire cost of the water works was \$50,000. The valuation of the town for purposes of taxation is upward of \$2,000,000.

NEW BRITAIN, the name of one large and several smaller islands in the Pacific ocean, between lat. 4° and 6° 30' S., and long. 148° and 152° 30' E.; extreme length of the large island about 800 m., breadth from 5 to 50 m.; area estimated at 12,000 sq. m. It is of crescent shape, and is separated on the W. from New Guinea by Dampier's strait, and on the E. from New Ireland by St. George's channel, the former being about 50 and the latter 25 m. wide. There are several fine bays and harbors, and at Spacious bay, the E. headland of which is in lat. 5° 2' S., long. 152° 7' E., there is supposed to be a channel extending across the island. In the interior there are high mountains, and in the N. active volcanoes. Bordering the coast are extensive fertile plains, and much of the surface is covered with forests. The principal productions are palmas, sugar cane, breadfruit, pigs, turtles, and fish. The inhabitants are a tribe of oriental negroes or negrillos, well made, and of very dark complexion.

NEW BRUNSWICK, a city and the capital of Middlesex co., N. J., situated at the head of navigation on the S. W. bank of the Raritan river, about 15 m. from its mouth, 30 m. from New York by the New Jersey railroad, and at the terminus of the Delaware and Raritan canal; pop. in 1860, 11,287, including 8 slaves. The oldest parts of the town are built on low land, but a large and by far the pleasantest portion is upon the high and sloping ground which, in the form of a crescent, half encircles

the original location. It is largely engaged in manufactures, having about 20 extensive establishments, which employ 1,400 hands and a capital of \$1,255,000, and whose annual products amount to about \$1,800,000. Among them are 4 factories of India rubber goods, 8 of paper hangings, 1 of printed cottons, 1 of leather, 1 of alcohol, and 1 of gas and coal tar. There are beside these 4 machine shops, 3 founderies, 2 sash and blind factories, and several smaller establishments. There are 2 banks with an aggregate capital of \$550,000, 2 fire insurance companies, and 8 building loan associations. Traffic is maintained by means of a daily steamboat line to New York, by the Delaware and Raritan canal to Philadelphia and intermediate places, and by the New Jersey and the Camden and Amboy railroads. A number of coasting vessels, engaged mostly in the transportation of coal, are owned here. There are 16 churches, viz.: 2 Baptist, 2 Episcopal, 1 Jewish, 3 Methodist, 2 Presbyterian, 3 Reformed Dutch, 1 Roman Catholic, and 2 union.—Rutgers college occupies an elevated and beautiful situation in the N. part of the city. Its buildings are the college edifice, built of freestone in 1809, and Van Nest hall, a brick building erected in 1847. The former contains recitation rooms, a philosophical room, library, and chapel; and the latter rooms for the literary societies, the cabinet of natural history, and the chemical laboratory. The faculty consists of a president and 9 professors. The number of students in attendance (Nov. 1860) is 120. It was established by friends and adherents of the Reformed Dutch church in North America, and was chartered under the name of Queen's college in 1770. The name was changed to Rutgers in 1825. It has always been under the patronage of the synod of the Reformed Dutch church, but it is open to all. Its professorships are partially endowed. Its libraries contain about 12,000 volumes. The philosophical and chemical apparatus and the collections in natural history are respectable and constantly improving. Students lodge and board in private families under the supervision of the faculty, though rooms are provided in Hertzog hall for those who have the ministry in view. The affairs of the college are controlled by a board of trustees. The theological seminary of the Reformed Dutch church, established here in 1810, occupies a commanding position N. of the college. It has a spacious building, called Hertzog hall, which contains recitation rooms, a library, a chapel, and rooms for 106 students. There are 3 professors and 60 students. The library contains 5,000 volumes. Among the other educational institutions are the grammar school of Rutgers college, 2 private classical schools for boys, a seminary for young ladies, a free Lancasterian school supported by an endowment, and a public school sustained by tax. There are 1,750 white and 70 colored children in the free schools, and 240 in private schools. The amount expended in 1859 in

supporting the public school was \$10,069. The periodical press comprises 2 daily and 3 weekly newspapers, and the Rutgers college quarterly.—New Brunswick was settled about the close of the 17th century by emigrants from Long island, and was incorporated as a town in 1736. During the revolutionary war it was at different times the head-quarters of each of the opposing armies, and remains of their works are still to be seen in the vicinity. The city was incorporated in 1784. In 1835 it suffered severely from a tornado.

NEW BRUNSWICK, a British colony in North America, bounded N. by the river Restigouche and the bay of Chaleur, which separate it from Lower Canada, E. by the gulf of St. Lawrence, S. by Nova Scotia and the bay of Fundy, and W. by the state of Maine. It lies between lat. 45° and 48° 5' N., and long. 68° 50' and 67° 58' W.; length from N. to S. 180 m., breadth 150 m.; area, 27,620 sq. m.; pop. in 1851, 198,800, including 1,058 colored and 1,116 Indians. The number of immigrants in 1851 was 3,470. The province is divided into 14 counties, and 61,273 acres of land have been assigned to the Indians. The capital is Fredericton, in the county of York, on the St. John, 80 m. from the bay of Fundy; and the principal commercial town is St. John, at the mouth of St. John river on the same bay.—The coast line of New Brunswick is about 500 m. in length, interrupted only at the point of junction with Nova Scotia, where an isthmus of not more than 14 m. in breadth connects the two territories, and separates the waters of Northumberland strait from those of the bay of Fundy. The principal bays and harbors are Bathurst bay on the N. coast, Miramichi bay on the E., and Passamaquoddy bay and St. John harbor on the S. There are numerous smaller harbors, more particularly on the S. portion of the E. coast. There are many rivers, streams, and lakes in the province, and from some parts of the interior a canoe can be floated either to the bay of Chaleur, the gulf of St. Lawrence, or the bay of Fundy. The largest river is the St. John, or Looshtook, which has its source in a lake of the same name in Maine, and in its upper course forms part of the boundary between Maine and Canada. After entering New Brunswick, it first flows S. and then S. E., and falls into the bay of Fundy at St. John, after a course of 450 m. The principal tributary of the St. John in New Brunswick is the Tobique. The Miramichi crosses the central part of the province in a N. E. direction, and falls into the bay of the same name in the gulf of St. Lawrence, and is navigated by large ships for 25 m. The Restigouche, which divides New Brunswick from Canada, is formed by 5 main branches, and falls into the bay of Chaleur after a course of 200 m. The Nepisiguit, 100 m. long, which flows through the N. E. part of the province, also falls into the bay of Chaleur. The Petitcodiac falls into the N. part of the bay of Fundy, and is navi-

gable 25 m. for vessels of large size. In the N. part of the province there are many lakes, but none of any considerable size; in the S. there are a few somewhat larger, the most important of which are Grand lake, 20 m. long and about 5 m. broad, and Washademoak lake, about 20 m. long and 2 m. broad, both lying between St. John and Fredericton.—New Brunswick cannot be considered mountainous, but the N. and N. W. parts partake more of this nature than any other portion of the province. A branch of the Appalachian mountains enters the N. W. of the province from Maine, and runs across to the bay of Chaleur. The mountains are of no great height, and some are entirely clothed with wood. The scenery of this district is very beautiful. Large tracts of flat alluvial soil lie along the numerous rivers that intersect the country. The surface of the S. part is much broken and diversified with rocks and ravines, and the whole coast of this region is bold and rocky. East of the St. John the soil is deep and fertile, and covered with tall and dense forests. To the W. of that river the land is rather poorer, but there are many watered valleys covered with forests interspersed with corn fields. For nearly 20 m. inland along the shore of the gulf of St. Lawrence the country is flat and fertile; but in the interior it rises into gently sloping hills, which extend westward as far as the St. John. The geology of the interior is not minutely known, but the formation of the parts that have been inspected presents no remarkable features. Several salt springs are found, and some of the strata are very rich in fossil remains, which are remarkable in many cases for the distinctness with which they have been preserved. Iron ore is abundant, and copper has been found on the banks of the Nepisiguit, and plumbago near St. John. There is a coal field in the central counties, which covers an area of about 10,000 sq. m.—The climate is remarkably healthful. The S. part is considerably milder than the N., but the whole country is covered with snow for about 4 months in the year. At Fredericton the temperature ranges from 85° below zero to 95° above, and the mean is about 42°. The coldest part of the winter is between December and March, and the most snow falls in February. About the middle of March the S. winds set in, and soon afterward the ice breaks up on the rivers and lakes. The spring is generally cold and rainy, but in summer the weather is commonly dry. The S. W. wind is warm and agreeable, except on the shores of the bay of Fundy, where its vapor is condensed in thick fogs which prevail during the summer; but these fogs do not extend more than 15 or 20 m. into the interior. The shifting of the wind produces a great change of temperature in New Brunswick, which has been known to rise or fall 60° in 24 hours. The clearing of the forests has already greatly mitigated the severity of the winters, and shortened their duration, for the shade afforded by the woods protects

the snow from the effects of the sun. During the autumn, and especially in the time called the Indian summer, the weather is particularly agreeable.—The chief vegetable production of New Brunswick is timber, of which there is the usual variety found in North American forests; but the pine is the principal kind exported. Indian corn is grown in the S. parts of the province; flax, wheat, and other cereals, and good potatoes, are raised. Much of the land, including the extensive marshes which have been reclaimed from the sea, offers extraordinary advantages for breeding and feeding cattle, and for the establishment of dairies upon an extensive scale. The wild animals are bears, moose deer, foxes, wild cats, raccoons, beavers, otters, and porcupines. The rivers and lakes abound in salmon, trout, chub, eels, and perch; and cod, mackerel, and herring are abundant on the coast.—The chief part of the inhabitants are British settlers and their descendants. There are a few of French stock, who are principally settled on the bay of Chaleur; and there are some Micmac and Melicete Indians, the former in the N. part of the province, and the latter in the valley of the St. John. The people of New Brunswick are mostly employed in agriculture, in the fisheries, in cutting timber in the woods and preparing it for exportation, and in ship building. The principal seats of the fisheries are the harbor of St. John and the islands at the mouth of the bay of Fundy, the whole of its shores on the gulf of St. Lawrence, and in the bay of Chaleur; and cod, haddock, herring, and mackerel are the fish chiefly caught. The timber is felled and hauled over the snow to the rivers, down which it is floated to the saw mills, of which there are many in the province. Of the 17,677,860 acres constituting the area of New Brunswick, about 12,000,000 acres are capable of profitable cultivation, and much of the remainder might easily be reclaimed. About 5,000,000 acres have already been granted to settlers, and 11,000,000 are yet in the hands of the government of the colony. Of these ungranted lands $\frac{2}{3}$ lie to the E. of the St. John. The land under cultivation in 1854 was 648,954 acres. The chief crops in 1855 were 206,635 bushels of wheat, 1,411,164 of oats, and nearly 3,000,000 of potatoes. There were 22,044 horses, 106,263 horned cattle, 168,039 sheep, and 47,982 swine. In different parts of the country, wheat, barley, and peas have yielded 40 bushels per acre; oats, 60 bushels; Indian corn and buckwheat, 65 bushels; carrots and mangel wurzel, 80 tons; turnips, 1,000 bushels; and potatoes, 500 bushels. Ship building is extensively carried on, and many of the vessels constructed are of very good models and fast sailers. They are built principally on speculation, loaded with timber, and sent to find a market in England. The number built in the province in 1854 was 185, and their tonnage 99,426; in 1855 the number was 95, and their tonnage 54,561. The number of vessels belonging to the port of St. John in 1855 was

866, tonnage 188,292. The number of entrances in 1856 was 8,700, tonnage 625,867; clearances 3,745, tonnage 100,886. The trade of New Brunswick has benefited very considerably by the reciprocity treaty between British America and the United States, which has opened a ready market for the produce of the province and the coast. During the year 1857-'8, 218 American vessels entered St. John from various ports, principally in the United States, and the same number cleared. The value of their import cargoes is officially stated at \$201,511, and that of their export at \$446,712; but a considerable portion of the latter was conveyed to Europe and other parts of the world. In 1855 the total value of the imports was £1,481,380, and of exports £826,381 (against £2,068,173 and £1,104,215 in 1854); the latter of course not including the amount realized upon vessels sent out of the country for sale. The number of saw and grist mills in the province in 1851 was 845, employing 4,666 hands. There were also 125 tanneries, 11 founderies, 52 weaving and carding establishments, 8 breweries, and 94 other factories.—Considerable attention is paid to education. At Fredericton there is a university, founded in 1828, in connection with the civil and ecclesiastical government of the province. It has an endowment of 6,000 acres of land near the capital, and receives £1,000 a year from the crown and the same amount from the colonial government. There is a Methodist and also a Baptist college; and grammar and parish schools have been established in every county. The parish schoolmasters are paid sums varying from £18 to £40 per annum. The whole number of school houses in 1851 was 798. There is a marine hospital, a lazaretto, and a lunatic asylum. The amount of money expended in 1854 for educational and charitable purposes was £17,269. None of the religious denominations in New Brunswick are supported by the government. The lieutenant-governor of New Brunswick (in 1860, the Hon. Manners Sutton) has a salary of £8,000. He is assisted by an executive council of 8, a legislative council, and a representative house of assembly. In 1855 the public revenue amounted to £98,916, and the expenditures to £188,858. The British exchequer contributed in 1857 £9,480 to the expenditures of the province. The military force of New Brunswick consists of a regiment of yeomanry cavalry, 8 troops of cavalry, a regiment of artillery, and 18 regiments of infantry, numbering in all 27,200 rank and file.—New Brunswick and Nova Scotia originally formed one French colony, called Acadia or New France. The aboriginal inhabitants consisted of several tribes of Indians, but there are now only two tribes left. They wander about the country in small parties, but assemble annually to arrange their fishing and hunting, and affairs concerning their general welfare. The country was first settled by the French in 1689, and by the treaty of Utrecht was ceded to the English in 1713. In 1764 it

was first settled by British colonists; in 1784 it was separated from Nova Scotia and formed into a distinct province. When the United States gained their independence many of the British adherents emigrated to New Brunswick, and their descendants now form a considerable portion of the population.

NEW CALABAR. See **CALABAR.**

NEW CALEDONIA (called *Balade* by the natives), an island of Australasia belonging to France, in the S. Pacific, between lat. 20° and 22° 30' S., and long. 164° 5' and 167° E.; length from N. W. to S. E. about 200 m., breadth 80 m.; pop. estimated at 60,000. It is surrounded by dangerous rocks, sand banks, and coral reefs, and is accessible by only two channels, one of which, between the S. end and Botany island, was discovered in 1849 by Capt. Woodin, whose name it bears. It has several bays where ships may anchor near the shore, beside which there are secure harbors at Port Balade on the N. E. part of the island and Port St. Vincent on the S. W. The interior is occupied principally by barren mountains, rising in some places to a height of 8,000 feet, and abounding in granite, quartz, mica, steatite, and green amphibole. Coal and iron are found among these hills, and indications of gold have recently been discovered. A few fertile valleys are interspersed, in which grow the cocoanut, banana, taro, mango, breadfruit, and yam. Vegetation in such spots is luxuriant. The sugar cane and vine grow wild, and the former is of excellent quality and to some extent cultivated. There are many large and well watered plains which afford excellent pasturage, and forests of sandal wood extend from the coasts 10 or 12 m. into the interior. Tripang is fished in the surrounding waters. The natives resemble the Papuan or negrito race, and speak a language kindred with the Australian tongues. They belong to different tribes, some of which are described as hospitable and honest, while others are cruel and treacherous cannibals. They are well formed, tall, robust, and active. Their skin is deep black, and their hair coarse and bushy. They are fond of painting and tattooing their bodies, which are encumbered by few garments, and those of the simplest and scantiest description. Their huts, built of spars and reeds, thatched with dried grass, and entered by a very small opening, bear some resemblance to bee-hives. The chief articles of food are yams and fish.—New Caledonia was discovered by Capt. Cook in 1774, and visited by D'Entrecasteaux in 1792. A settlement of Europeans at Balade was attacked by the natives in 1849, and several of the settlers were killed. The same year the captain and cook of the ship *Mary* were killed and eaten. The French took possession of the island in Sept. 1853, and established on it a station for their Pacific squadron. They have since been repeatedly at war with the islanders, but hostilities were closed in 1857, when the most troublesome chief was made prisoner. The French colonists have not been uniformly

successful, many of them having fallen victims to the ferocity of the natives. The French missionaries, however, have made several prosperous settlements, and cultivate plantations. They have introduced a variety of vegetables and fruits, including wheat and barley, and have been very successful in raising live stock. Great numbers of the islanders have embraced Christianity. They are found to be industrious and averse to drunkenness. The French governor, who resides at Port de France, which was founded in 1854, has authority over all the French possessions in the Pacific.

NEW CASTLE, a N. co. of Del., bordering on Penn., bounded E. by Delaware river and bay, which separate it from New Jersey, and drained by Brandywine, Christiana, and other creeks; area about 500 sq. m.; pop. in 1860, 54,858, of whom 254 were slaves. It has a diversified surface and fertile soil. The productions in 1850 were 1,066,877 bushels of Indian corn, 319,012 of wheat, 483,987 of oats, 121,846 of potatoes, 24,417 tons of hay, 766,808 lbs. of butter, and 14,372 of wool. There were 12 cotton and 4 woollen factories, 4 iron founderies, 2 forges, 7 machine shops, 24 grist mills, 8 paper, 8 powder, and 9 saw mills, 5 ship yards, 5 tanneries, 73 churches, 2 colleges, 8 newspaper offices, and 4,258 pupils attending public schools. It is intersected by the Philadelphia, Wilmington, and Baltimore, the Frenchtown and New Castle, and the Delaware, New Castle, and Wilmington railroads.—**NEW CASTLE**, the capital, is situated on the Delaware river, 5 m. S. from Wilmington, 42 N. from Dover, and 32 S. W. from Philadelphia; pop. in 1860, 3,468. It contained in 1850 a bank, a public library, an arsenal, and 5 churches, viz.: 1 Episcopal, 2 Methodist, 1 Presbyterian, and 1 Roman Catholic. New Castle has also a large manufactory of locomotives and other machinery.

NEW ENGLAND, the north-eastern portion of the United States, comprising the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut. It extends from lat. 41° to 48° N., and from long. 67° to 74° W., with an aggregate area of 65,000 sq. m. It has a coast line of about 700 m., without allowing for the smaller inlets, and constitutes a large part of the great peninsula which, including Nova Scotia, New Brunswick, and parts of Lower Canada, is formed by the Atlantic ocean, the St. Lawrence, and the connected waters of Lakes Champlain and George and the river Hudson—an interesting feature in the topography of the continent fully described in the opening chapter of Palfrey's "History of New England." It was originally granted for colonization by James I. in 1606 to the Plymouth company under the name of North Virginia, and received its present name from Capt. John Smith, who in 1614 explored and made a map of the coast.—For the details of the geography and history of New England, see the states respectively of which it is composed.

NEW GRANADA (called also *La Confederación Granadina*), a republic of South America, occupying the N. W. corner of that continent, between lat. 8° 35' S. and 12° 30' N., and long. 65° 50' and 83° 5' W. It is bounded N. by the Caribbean sea, N. E. and E. by Venezuela, S. E. and S. by Brazil and Ecuador, and W. by the Pacific ocean and Costa Rica. It derives its name from the resemblance between the plain of Bogota, its capital, and that surrounding the city of Granada in Spain. Its geographical position is both remarkable and interesting. It lies between the Pacific ocean and Caribbean sea on one side, and the two great rivers the Orinoco and the Amazon on the other, and comprehends the isthmuses of Chiriqui, Panama, Darien, and Atrato, all of which have been indicated as available for interoceanic communication, and over one of which the greater part of the trade and travel between the seas now passes. Its population includes 1,500,000 whites, more than one half of the total, which is a larger proportion than is found in any other Spanish American state. It is divided into 8 departments or states, as follows:

States.	Area in sq. m.	Pop. in 1850.	Capitals.	Popula- tion.
Antioquia.....	19,890	244,243	Medellin.....	19,000
Bolivar.....	20,520	182,157	Cartagena.....	10,000
Boyaca.....	20,700	579,689	Tunja.....	8,000
Cauca.....	171,000	830,381	Popayan.....	7,500
Cundinamarca.....	54,000	617,648	Bogota.....	60,000
Magdalena.....	16,740	73,098	Santa Marta.....	5,000
Panama.....	17,550	188,808	Panama.....	9,000
Santander.....	12,600	878,376	Bucaramanga.....	12,000
Total.....	833,000	2,243,837		

The capital is Bogota, or Santa Fé de Bogota, which is also the capital of the state of Cundinamarca.—Among the 40 bays and ports of the republic on both oceans, the most important, commercially, beside the free ports of Panama and Colon (Aspinwall), are Cartagena, Santa Marta, Sabanilla, and Rio Hacha on the Atlantic, and Buenaventura and Tumaco on the Pacific. Chiriqui lagoon and Porto Bello on the Atlantic are also fine ports; beside which, on the Pacific, may be mentioned Humboldt harbor, Cupica, and San Juan or Charambira. The first named has been proposed by Mr. Kelley, and the second by Humboldt, as proper termini for interoceanic canals by way of the rivers Truando and Napipi, which are affluents of the river Atrato, flowing into the Atlantic. San Juan was once connected with the upper waters of the Atrato by a small canal, constructed by a priest in 1788, and called the canal of Raspadura.—The natural configuration of New Granada is peculiar. The Cordillera of the Andes, from the point where it enters the country from the S., forming the plateau of Pasto and Tuquerres, elevated 14,000 feet above the sea, opens out like a fan, or rather like an extended hand, in three great ranges, called the eastern, central, and western, between which are the two large and beautiful valleys of Cauca and Magdalena,

differing in altitude and climate, leaving on the W. the valley of the Atrato, and on the E. the valleys of the tributaries of the Orinoco and Amazon. From the Paramo de las Papas, one of the most remarkable summits of the world, descend, in different directions, the rivers Caqueta falling into the Amazon, the Guachicono into the Pacific, and the Magdalena and Cauca, both starting from the same lake, but separated for a while in their course by majestic mountains (among others, those of Tolima, 18,800 feet high), and finally uniting and falling into the Caribbean sea. The E. branch of the Cordilleras is much the greatest in extent; it forms what may be called the heart of the republic, and consists of a series of great table-lands or plateaux, from 8,000 to 14,000 feet in elevation, cool and salubrious, where the Caucasian race flourishes in all its strength, to the exclusion of the African, who naturally seek the hot valleys of the coast. In this plateau, which extends from Bogota to near Venezuela, the ancient Chibchas had their seat. It produces in greatest profusion the fruits and grains of the temperate zone, and contains more than one third of the population of the republic, which in some parts is concentrated to the number of 2,600 inhabitants to the square league. The great rivers Negro, Caqueta, and Putumayo connect the E. and S. E. of the republic with the Amazon; and the Guaviare and the Meta (now navigated by steamers) and its affluents with the Orinoco. The republic has the right of navigating the Amazon proper, which separates it from Brazil, as also of navigating the Orinoco, which constitutes in part its boundary on the side of Venezuela. But the most important river is the Magdalena, with its tributary the Cauca, together 2,000 m. in length, and traversing almost the entire republic, from N. to S. The former is navigated by steamers for 700 m. to the rapids of Honda. Whenever enterprise shall overcome these rapids, and restore the old canal which ran from the river to the port of Cartagena (which it is estimated can be done for \$150,000), the river will become one of the most important water-ways of all South America, and will accommodate at least three fifths of the entire inhabited territory of New Granada, now having a commerce of not less than \$21,000,000. The river Atrato is scarcely less important; it has a length of 300 m., and, it is believed by many, will some day afford an important aid in uniting the two oceans. The rivers Patia and San Juan are the most important falling into the Pacific, and may be greatly improved, with advantage to commerce, inasmuch as they communicate with the high, salubrious, and fertile districts of Popayan, Pasto, Tuquerres, and the famous valley of Cauca, which Bolivar called "the Italy of America."—The fauna and flora of New Granada combine almost the entire range of the tropical, intertropical, and temperate zones. The traveller frequently encounters in a single day's journey the four seasons of the year, and the

vegetable peculiarities of the three central zones of the globe. He finds wheat, potatoes, the breadfruit, the *quina* (Peruvian bark), *pitayo*, cedar, balsam of Tolu, vanilla, *lignumvitæ*, mahogany, wax tree, caoutchouc, and the three trees perhaps most precious of all, viz.: the *albataque*, the vine of the cross, and the *arisa*, all remarkable specifics, the first against inflammation, the second for stanching effusions of blood, and the third for instantaneously stopping bleeding at the nose. Pearls, mother of pearl, tortoise shell, and coral abound on the coasts of Panama and Carthagena. The changeable butterfly of Muzo is without a rival in its beauty, as also the curious and brilliant bird of Velez, called *sol y luna* (sun and moon) from having the image of both those luminaries portrayed on its wings. In the vast unexplored forests popular tradition reports the existence of the *panchique* and *manacarita*, enormous quadrupeds never seen alive, but whose tracks, those of the first round, and those of the second marked with three great toes, have been often observed in the mountains of Coconuco in Popayan, and at Piedecuesta in Santander. It is affirmed that on the line of the tracks of the *panchique* the branches of the trees have been broken off to the height of 15 feet.—The geological conditions of New Granada are equally extraordinary and perplexing, and must ultimately attract the study of scientific men. Everywhere are found traces of stupendous cataclysms, and a disarrangement and intermixture of primitive and sedimentary rocks, which seem to put all classification at defiance. In places great rivers and even small streams have cut through mountains of the hardest rocks, leaving dizzy escarpments on either hand; in other places we come suddenly on enormous subsidences in the earth, as if the props of its surface had suddenly given way, or vast caverns glistening with stalactites; while everywhere colossal masses, lifted high above the general level, attest the violence of volcanic agencies. These agencies are still active in some places, as in Batan near Sogamoso, where the soil is so much heated that, although in the heart of the Andes, it produces all the fruits of the tropics. The celebrated New Granadian geologist, Joaquín Acosta, describes great glaciers which he saw in the Paramo of Ruiz, a phenomenon which escaped the attention of both Humboldt and Boussingault.—From Costa Rica to Venezuela, New Granada abounds in rich, auriferous alluvions of great extent. There is hardly a state which does not possess in its soil more or less gold. It is claimed that Choco, Antioquia, Mariquita, Popayan, Pamplona, Ocaña, Bucaramanga, and other places are exceedingly rich in that metal. Even now, though rudely worked by a few laborers, they produce annually from \$10,000,000 to \$12,000,000 worth. The auriferous sands of Antioquia, according to M. Dufrenoy, afford results very nearly coinciding with those of California. Choco produces nearly all the platinum, and Muzo the emeralds, which

are now found in foreign markets; and in various parts of the country are mines of silver, copper, lead, iron, quicksilver, coal (in Bogota, Cali, Soata, Chiriqui, &c.), amethysts, and other varieties of rare and valuable stones and minerals. The great coal bed of Cali, it is believed, extends beyond the Cordilleras to the Pacific.—The late Col. Codazzi has demonstrated that in the highlands of Bogota, Tunja, and Velez, where is now the densest population, there once existed a system of broad and deep lakes, which, breaking through the barriers that encircled them, precipitated themselves through what is now the river Suarez or Sogamoso into the ocean, leaving the rugged traces of their irruption boldly marked on the face of the country. The same authority conceives that this great cataclysm may have occurred within the past four centuries. Some evidence in support of his theory is afforded by two great stones which have been discovered on opposite sides of what must have been the borders of the principal lake; both face toward the points of rupture of the mountains, and the faces of both are covered with sculptures, among which are distinguishable figures of the frog (the Chibcha sign of water) with outspread feet, and human figures with upraised arms, in attitude of surprise or alarm. The Cojines de Tunja, the Calzada del Llano de Patagñi, and the ruins of Infernito are remarkable remnants of Chibcha architecture. The last named consists of 100 beautiful round columns of green sandstone, one 15 feet high, probably belonging to some palace or temple. Beyond the limits of the Chibcha kingdom, on the head waters of the river Magdalena, are found innumerable ancient relics of stone, the probable remains of a race more cultivated than was found there in 1537.—Among the natural curiosities of the country may be mentioned the falls of Tequendama near Bogota, upward of 700 feet high; the natural bridge of Pandi or Icononzo, spanning the river Sumapaz at an elevation of 600 feet; the cascade of the Rio Vinagre, so called from the sulphuric acid with which its waters are charged; the great orifices called Hoyo del Aire and Hoyo de los Pajaros, near Velez; the Peñon de Quitisoque, from the symmetrically pierced summit of which fall 3 beautiful streams of water; the Fura-Tena (man and woman in the Chibcha language), and the Boqueron de Peña Armada, which are two stupendous cuts or excavations made by the Rio Minero, the second 10,650 feet deep; and the natural tunnel of the Rio Suarez.—The people of New Granada are generally distinguished for their aptitude, festive humor, and generous impulses. They are hospitable, and invincible in their repugnance to military rule, to such a degree that no military chief has ever succeeded in establishing himself in power. The educated classes rank among the first in South America for their scientific and literary culture. The people of Socorro and Antioquia have been called the "New Englanders

of New Granada," from their laborious industry and their mercantile enterprise. The women of Antioquia, Bogota, Ocaña, and other cities are celebrated by travellers for their grace and beauty.—The interior commerce of the country is greater than the exterior. The annual exports and their values are given approximately in the following table:

Gold	\$5,000,000
Platinum, silver, emeralds, &c.	1,000,000
Pearls and tortoise shell	800,000
Tobacco, from Ambalema, Cauca, &c.	3,500,000
Panama hats	1,400,000
Other manufactures	50,000
Quinine	600,000
Dye woods and timber	500,000
Coffee	500,000
Hides	500,000
Cacao	80,000
Cacothous (India rubber)	50,000
Maise, vegetable ivory, rice, balsam, &c.	300,000
Total	\$14,180,000

Industry in the country is generally backward, and travel is difficult from the absence of good roads.—The constitution of New Granada is closely modelled after that of the United States. Complete freedom in religion and worship is conceded, and there is absolute independence of church and state. Trial by jury, freedom of the press, free navigation of the interior waters of the republic for all flags, prohibition of monopolies, abolition of slavery and the penalty of death for political offences, gratuitous primary education, the establishment of a public school in every parochial district, equal rights of foreigners with citizens, freedom of foreign and domestic periodicals from postage, a decimal money system, freedom of the ports of the isthmus of Panama, and liberal encouragement of emigration, are among the laws and guarantees which have distinguished the policy of the country and its government. The public treasury, although weighed down by an exterior debt of \$34,500,000, inherited from the old republic of Colombia, has been managed with great integrity. The revenue has fallen to about \$2,000,000 annually, chiefly in consequence of the abolition of the tobacco monopoly, and the surrender of imposts on the transit of the isthmus of Panama. There are 800 public schools, 60 seminaries and colleges for higher and professional instruction, 47 printing establishments, 40 periodicals, various literary and scientific societies and theatres, 3 hospitals, 2 asylums, one of which is for orphans, and a number of savings banks for the poor, administered gratuitously, and paying an interest of 1 per cent. a month. Efforts are now making to finish the "Physical and Political Geography of New Granada," a work of great extent and value, commenced by Col. Codazzi, and cut short by his death.—The principal aboriginal nation of New Granada was Chibcha, or Muisca, ranking fourth in the list of semi-civilized American families—the Tzendals or Toltecs being first, the Nahuatl or Aztecs second, and the Quichuas or Peruvians third. The early chroniclers represent them as frugal, industrious, and happy, with a well organized government and a

systematized religion. They believed in the teachings of the beneficent demi-god Nemquetaba (envoy of God), who corresponded in character with Manco Capac in Peru, and Quetzalcoatl in Mexico. He made his first appearance to man, according to the Chibcha tradition, seated on a rainbow. The sovereignty of the Chibchas was divided between the *sipa* or lord, who resided in Muequeta, now Frenza, and the *sague*, signifying also lord, who lived in Hunsa, now Tunja. There was an elective high priest, whose seat was in Iraca, now Sogamozo, who had the right of final mediation between the *sipa* and the *sague*. They believed in the immortality of the soul, and, it would seem, had some notion of a triune God. Their language was soft and fluent, rich in words, and full of sonorous diphthongs. The sound *ca* was often repeated, as in the Italian. Although at the time of the discovery numbering upward of 2,000,000, and having chieftains distinguished in war, yet they were reduced by Ximenes de Quesada, a lawyer transformed into a general, but nevertheless worthy to rank with Cortes and Pizarro, at the head of but 166 Spaniards. The natives of the coast of the Atlantic, from Chiriqui to Goajira, are of the Carib stock, and very similar to the Guaranis of Brazil. Some nations are still in a savage state, as the Mesayos, Caquetes, Choques, Mochoas, Omaguas, Goajiras, and others. These still preserve their languages, but the Chibchas and allied nations have nearly lost theirs, and now speak Spanish. The Mesayos and some others are said to be cannibals, with very indistinct ideas of a Supreme Being.—The coasts of New Granada were discovered by Alonzo de Ojeda in 1499, and visited by Rodrigo Bastidas in 1501, and by Columbus in 1502. The conquest was effected in 1536-'7, and the country erected into a viceroyalty in 1718. The first efforts for emancipation from Spain were made in 1781 and 1795; independence was proclaimed in 1810, and secured by Bolivar in 1819. The union of the country with Venezuela and Ecuador, in the republic of Colombia, was dissolved in 1830, and the present republic of New Granada finally organized in 1832, since which period there have been 7 successive administrations in the government, each completing its constitutional term of 4 years, viz.: that of Gen. Santander, from 1833 to 1836 inclusive; Dr. Marquez, 1837-'40; Gen. Herran, 1840-'44; Gen. Mosquera, 1845-'8; Gen. Lopez, 1849-'52; Gen. Obando, whose term was concluded by the vice-presidents Obaldia and Mallarino, 1853-'6; and Dr. Ospina, 1857-'60. Every revolution attempted in New Granada has succumbed to the constitution and laws, and civil government has been uninterrupted.—See J. Acosta, *Historia del descubrimiento, conquista, y colonizacion de Nueva Granada* (Paris, 1849); Mosquera, "Memoirs on the Geography of New Granada" (New York, 1853); and J. F. Holton, "Twenty Months in the Andes" (New York, 1856).

NEW GUINEA, or **PAPUA**, next to Australia the largest island of Australasia, lying between lat. $0^{\circ} 15'$ and 10° S. and long. $131^{\circ} 20'$ and $149^{\circ} 20'$ E.; length 1,200 m.; area estimated at 200,000 sq. m. To the S. it is divided from Australia by the straits of Endeavor and Torres, the latter of which is about 80 m. broad; on the N. it is washed by the Pacific ocean; on the E. it is separated from New Britain by Dampier strait; and on the W. are Ceram and the other islands of the Molucca sea. It is of irregular outline, and the coasts are in many places deeply indented with bays. Little is known of the whole island, and until very lately the acquaintance of Europeans with it has been confined to a few places on the coast. The interior has not been explored by white men, but recent travellers describe the whole northern peninsula of the island as rugged and mountainous. A succession of jagged ranges stretches far away into the interior, and is visible from both the N. and S. coasts; it runs E. and W., and the highest peaks appear to be covered with snow. No traces of volcanic action are to be found, slate and limestone being the rocks chiefly met with. The rivers of New Guinea are unknown, the mouths of a few only having been seen; but it is inferred from the great height of the mountain range in the interior, and its distance from the coasts, that there must exist some considerable streams. In lat. 5° and long. $137^{\circ} 30'$ the Dutch discoverers of 1828 examined the mouth of a river which they estimated to be more than half a mile broad, but at a short distance above it was found to branch off into three different streams. The climate of New Guinea is warm, and is said to be exceedingly moist, with heavy rains from March to October. The whole island appears to be one luxuriant forest, and many of the trees reach the height of 180 feet. The accounts of all the navigators who have touched on its coasts agree in describing it as a rich and magnificent country, containing, in all probability, the most valuable vegetable products of the Moluccas. Forrest found the nutmeg tree on an island situated near the coast; and he learned that a people in the interior, called Haraforas, cultivate the ground and bring their produce down to the sea coast; that they are very poor, and some of them have long hair; and that they live in trees, which they ascend by cutting notches in them. The hog is the only large mammiferous land animal found in New Guinea. The Dutch naturalists, who resided on the S. coast for 8 months in 1828, only found 6 mammifers, and all of them belonged to the marsupial or pouched class of Australia; two of them were kangaroos, but differed from all others of the same family by their singular habit of living in trees. The feathered tribes are of great beauty and infinite variety. New Guinea is the native country of the bird of paradise, which is said to migrate in large flocks, in the dry season, to the islands lying to the W. and N. W. During

the residence of the Dutch on the S. coast, they collected 119 species of birds, belonging to 60 genera. In this collection, birds of prey were rare, and the family of the pies altogether wanting. The most numerous families consisted of the insect eaters, parrots, and pigeons. There were many aquatic birds, both web-footed and waders, but more especially the latter. The Dutch naturalists also collected 26 different species of reptiles, viz.: 15 lizards, 5 serpents, 5 frogs, and 1 tortoise. Fish were found in abundance on the coast.—The inhabitants of New Guinea are a variety of the negrillo or oriental negro, and it is inferred that they are of the same race throughout the island. No other indigenous race has been found on any part of the coast, and the prisoners brought from the interior and sold as slaves are found to be the same. The Papuan negroes are below the middle height, or about 5 feet 4 inches; their complexion is deep brown or black; the nose is flat with wide nostrils; the mouth is large, with thick lips and good teeth. The hair of the head grows in spiral detached tufts about 10 inches long, and the beard and whiskers are frizzly. A very wide difference seems to exist in the state of society in different parts of the island. The inhabitants of the W. coast, having been for ages in communication with the people of the Indian archipelago, more especially with those of the Moluccas, have received a certain portion of their civilization. They have consequently good dwellings, and are decently clothed; they build large rowing and sailing boats, and have a knowledge of iron; they cultivate some ground, and have two domestic animals, the hog and the dog. Toward the E. the tribes become gradually more barbarous. In 1822, when the Dutch visited the S. coast, opposite the gulf of Carpentaria in Australia, they encountered, instead of the peaceable inhabitants of the opposite shores, a tribe of naked and ferocious savages, who avoided every attempt made to hold intercourse with them. They had canoes, but no domesticated animals, and did not know the use of iron. The inhabitants are divided into small, independent tribes, who speak different languages, and live in a state of almost continual warfare. On the N. and S. coasts the Dutch discoverers in 1828 and 1835 found it necessary to procure fresh interpreters when they moved even a few miles. The population of New Guinea must be small, but there is no means of forming any correct estimate of its amount.—The island was discovered in the early part of the 16th century by the Portuguese, by whom it was named New Guinea from the striking resemblance between its inhabitants and those of Guinea in Africa. The Malay and Javanese call it Tannah-puwah-puwah, which means the land of the woolly or frizzled, and this has been corrupted into Papua. The Dutch were the first European nation to attempt to form a settlement on New Guinea. In 1828 they began to erect a

fort in lat. 5° S. and long. 138° 30' E., but the climate proved so unhealthy that they were forced to abandon it. In 1845 H. B. M. ship Fly surveyed 140 m. of the S. E. coast of New Guinea within the Great Bight, and found the coast low, and intersected by many channels which appeared to be the estuaries of a large river. The boats ascended one of these for about 20 m., but as the inhabitants appeared to be of a warlike disposition it was thought imprudent to land. There were many villages seen at intervals along the banks. In the following year the schooner Bramble continued this survey along the S. E. shore of the bight, and as they proceeded S. it was found that the country improved in appearance. In 1848 the Rattlesnake, another British ship, accompanied by the Bramble, commenced a further survey of the S. E. part of New Guinea. They determined the positions of many reefs and smaller islands, and found the height of a mountain, in the neighborhood of the S. E. cape of the island, to be 13,205 feet above the sea. European and Mohammedan traders are found at Dorey in the N. part, and the Dutch, who have again formed settlements on the island and taken possession of it as far E. as long. 141°, carry on an active and exclusive trade between it and the Moluccas. The population of the Dutch possessions on the coast amounted in 1859 to about 100,000. The governor in 1860 was Lieut. Col. Nagtglas. The value of the trade with the Netherlands is estimated at \$600,000.

NEW HAMPSHIRE, one of the 13 original states of the American Union, bounded N. by Canada East, E. by Maine and the Atlantic, S. by Massachusetts, and W. by Vermont, from which it is separated by the Connecticut river. It is situated between lat. 42° 41' and 45° 11' N., and long. 70° 40' and 72° 28' W.; length from N. to S. 176 m., extreme breadth 90 m., average breadth 45 m.; area, 9,290 sq. m., or 5,939,200 acres. The state is divided into 10 counties, viz.: Belknap, Carroll, Cheshire, Coos, Grafton, Hillsborough, Merrimack, Rockingham, Strafford, and Sullivan. Concord, on the river Merrimack, is the seat of government. The other most important cities and towns are Manchester, Portsmouth, Dover, Nashua, Keene, Exeter, Peterborough, Laconia, Somersworth, Rochester, Claremont, Hanover, and Haverhill.—The population of New Hampshire in 1790 and at the subsequent decennial periods was as follows:

U. S. Census.	Whites.	Colored.	Total.
1790.....	141,111	798	141,899
1800.....	182,893	864	183,757
1810.....	212,890	970	213,860
1820.....	243,256	925	244,181
1830.....	283,721	607	284,328
1840.....	294,066	583	294,649
1850.....	317,456	520	317,976
1860.....	323,175

Of the white population in 1850 there were 155,960 males and 161,496 females; of the

colored, 260 were males and 260 females. Deaf and dumb, 162; blind, 184; insane, 378; idiotic, 351. Density of population, 34.26 to the square mile; proportion to that of the whole Union, 1.87 per cent. Dwellings, 57,889; families, 62,287. Born in New Hampshire, 261,591; in other states, 42,636; in foreign countries, 13,571; unknown, 178; natives of New Hampshire in other states, 109,878. The original population of New Hampshire was almost exclusively of English and Scotch descent, and the rural districts still remain without much intermixture.—New Hampshire has but 18 m. of sea coast, and the shore in most places is a sandy beach, bordered with salt marshes. There are numerous creeks and coves, which form harbors for small craft; but Portsmouth, at the mouth of the Piscataqua, is the only haven for large ships. About 8 m. off the coast lie the Isles of Shoals, 8 in number, 3 of which belong to New Hampshire. They are inhabited by a hardy race of fishermen, and have for 2 centuries past been noted for the superior quality of their dried cod, known in the market as the Isles of Shoals dunfish. For about 20 to 30 m. back from the shore the country is level, occasionally diversified with hills and valleys. Beyond this the hills increase in number, and in many parts rise into lofty mountains, particularly toward the N. part of the state, where the White mountains are situated. The White mountains proper extend only from 14 to 20 m., but detached groups are found throughout New Hampshire, and the whole are sometimes regarded as a continuation of the Appalachian range. The principal mountain peaks of the state are Grand Monadnock, near the S. W. corner, 3,450 feet above the level of the sea; Chocorua in Albany, 3,858 feet; Sunapee mountain, near Sunapee lake; Kearsarge mountain, between Sutton and Salisbury, 2,461 feet; Carr's mountain in Ellsworth; Moosehillock in Benton, 4,686 feet; Mt. Washington, the most elevated peak of the White mountains, 6,285 feet high; and Mt. Lafayette, at Franconia Notch, 5,500 feet. With the exception of the strip bordering the ocean, the whole state is mountainous and broken, but there are many fine valleys through which the chief rivers have their course. The general slope of the country is from N. to S. The Connecticut river, which is the largest stream, rises near the N. extremity, and forms nearly the whole W. boundary; the chief tributaries which it receives from this state are the Upper and Lower Ammonoosuck in the N., and the Ashuelot in the S. The Merrimack is formed by the junction of the Pemigewasset, which rises in the White mountains, and the Winnepesogee, the outlet of the lake of the same name, at Franklin, and runs S. through the middle of the state to Massachusetts. Baker's river, rising near Moosehillock mountain and uniting with the Pemigewasset at Plymouth, is one of its principal sources. The Salmon Falls

river and the Piscataqua, of which it is a branch, constitute part of the boundary line between Maine and New Hampshire. The Cochecho is a branch of the Salmon Falls; and the Lamprey and Exeter discharge their waters into the Piscataqua proper. The Merrimack and its branches, and the Salmon Falls, have numerous cataracts, and furnish a large amount of water power to Manchester and other manufacturing towns on their banks. The Androscoggin has a small part of its course in the N. E. of this state, and the Saco also has its source among the White mountains, and runs S. E. into Maine. The passage of the Saco near its head waters through the mountains forms the celebrated Notch, a remarkable chasm 2 m. long, and where narrowest only 22 feet wide. This is the only opening through the mountains, and after a heavy fall of rain the stream becomes much swollen. In 1826 a violent storm caused a slide of earth 2 m. from the Notch which crushed 9 persons, choked up the Saco river, and flooded the country. The Margalloway, which falls into Lake Umbagog, has part of its course in New Hampshire. About 110,000 acres of the surface of this state are covered with water. Winnepiseogee is the largest and most beautiful lake. It is about 25 m. long by from 1 to 10 broad, and contains about 860 islands, and its shores are indented with numerous bays. Umbagog lake, about 18 m. long and 10 broad, on the boundary between Maine and New Hampshire, is the source of the Androscoggin; Connecticut lake, the source of the river of the same name, is in the N.; and Sunapee and Squam lakes and several smaller bodies of water are the sources and recipients of many streams. With the exception of Niagara falls, the mountain scenery of New Hampshire attracts more tourists than any other natural object in the United States. The traveller may wander for weeks through a country which presents to the view a continual change of mountains, rivers, lakes, and waterfalls, and for which the grandeur and diversity of its scenery have procured the appropriate name of "the Switzerland of America."—The geological formations of New Hampshire are almost exclusively those of the ancient metamorphic rocks, the mica and talcose slates, quartz rock, granular limestones, granites, gneiss, &c. Though they contain numerous veins of metallic ores, none of these have proved of much practical importance. The most promising are the enormous beds of magnetic and specular iron ores of Bartlett, and the specular ores of Piermont on the western side of the state, neither of which have ever been worked. At Franconia a blast furnace (the only one ever built in the state) and some forge fires have been, with some interruptions, in operation since 1811, reducing the magnetic ores of that vicinity. Copper, zinc, and lead ores, most of the last argentiferous, are found in a large number of towns: A lead mine, largely argentiferous, and containing also a considerable quantity of copper, is successfully worked in Warren. A

vein, containing oxide of tin in small quantity and associated with arsenic, occurs in the town of Jackson. Granular quartz has been worked in the towns of Unity and Keene, and applied to a variety of purposes. It is ground between millstones and bolted, to be used either as a polishing powder or for the preparation of sand paper at the manufactory of that article in Rockingham, Vt. It has also been mixed instead of barytes with white lead. Acworth, near Bellows Falls, is celebrated for its beryls, specimens of which of gigantic size are found in the collections of minerals throughout Europe. There are also found tourmalines and mica in great perfection. The latter is extensively quarried at Alstead, a few miles S. of Acworth, and at Grafton, 35 miles N. It is sold at from \$2 to \$3 per lb. to be used for the windows in stoves, for lanterns, compass cards, &c. Sulphuret of molybdenum is found in many places, especially at Westmoreland; and graphite or plumbago is also a common mineral, which is worked for the manufacture of crucibles at Taunton, Mass. Steatite or soapstone is also found at many localities. It is obtained in the quarry in Franconstown, and also at that in Orford, in large blocks, which are cut to the dimensions of 6 feet by 8 and 7 feet by 5, as well as into slabs and smaller blocks. It is used for stoves, fireplaces, sinks, for rollers used in dressing cotton warp, and for other purposes.—The soil of New Hampshire is not generally very fertile, but by industry and skill the inhabitants have in great measure overcome its natural defects. The best lands are in the valleys of the rivers, some of which are subject to occasional overflows. The N. part of the state is chiefly pasture and wood land. The climate is severe, being somewhat colder than that of Maine, but more steady. Difference of elevation within the state, however, causes great difference in the degree of temperature; so much even as 20° to 25° between the valleys and the more elevated positions. In summer the heat sometimes rises to 100°, and in winter the cold has been known to freeze the mercury in the thermometer. In the neighborhood of the White mountains the winters are excessively cold, and the peaks are covered more or less with snow 9 or 10 months out of the 12, from which circumstance their name has been derived. All parts of New Hampshire are exceedingly healthful, and cases of remarkable longevity are very numerous. The cold weather begins about the middle of September and continues till May; and from the latter part of November till the opening of spring the whole country is covered thickly with snow, and the rivers are all frozen.—The natural productions of New Hampshire include the oak, pine, hemlock, ash, beech, birch, and other trees, which are largely exported in the shape of lumber. The sugar maple and the pitch pine are abundant. The native animals, though much thinned, are not yet exterminated; wolves, bears, and other wild beasts are still found in the N. part of the

state, and occasionally commit depredations on the farms. Wild fowl and game are abundant, and both lakes and rivers are well stored with fish.—On June 1, 1850, New Hampshire contained 29,229 farms under cultivation, covering 2,251,486 acres of improved and 1,140,926 acres of unimproved land; value of farms \$55,245,997, and of implements and machinery thereon \$3,341,125. The live stock consisted of 84,288 horses, 19 asses and mules, 94,277 milch cows, 50,027 working oxen, 114,606 other cattle, 384,756 sheep, and 63,487 swine; aggregate value, \$8,871,901; and the value of the animals slaughtered in the year then ending was \$1,522,873. Of wool there was produced 1,108,476 lbs.; of butter, 6,977,056 lbs.; and of cheese, 8,196,563 lbs. The grain crops for the same year were: wheat 185,658 bushels, rye 183,117, oats 978,861, Indian corn 1,578,670, barley 70,256, buckwheat 65,265, and potatoes 4,304,919; hay, 598,854 tons; clover seed 829, and other grass seed 8,071 bushels; flax seed, 189 bushels; flax, 7,752 lbs.; peas and beans, 70,856 bushels; tobacco, 50 lbs.; hops, 257,174 lbs.; silk cocoons, 191 lbs.; maple sugar, 1,298,868 lbs., and 9,811 gallons of molasses; beeswax and honey, 117,140 lbs.; wine, 844 gallons. The orchard products were valued at \$248,568, those of market gardens at \$56,810, and home manufactures at \$393,455.—Manufactures of various kinds are extensively carried on, the great water power of the rivers affording peculiar facilities for the economical use of machinery. By the census of 1850 there were 3,301 manufactories, each producing annually upward of \$500 worth of goods. Of this number 44 were engaged in cotton manufacture, capital \$10,950,000, employing 2,911 male and 9,211 female hands, consuming raw material worth \$4,839,429, and producing 113,106,247 yards of stuffs and 140,700 lbs. of yarn, valued at \$8,880,619; 61 woollen factories, capital \$2,437,700, employing 926 male and 1,201 female hands, consuming raw material worth \$1,267,329, and producing 9,712,840 yards of stuffs and 165,200 lbs. of yarn, valued at \$2,127,745; 29 iron foundries, furnaces, &c., capital \$238,700, employing 390 male hands, consuming raw material worth \$187,560, and producing 6,074 tons of pig, cast, and wrought iron, valued at \$888,100; 168 tanneries, capital \$441,975, consuming raw material worth \$543,779, and producing leather valued at \$900,421. The above list includes the principal manufactured articles of New Hampshire; but there are a great number of others, which taken in the aggregate would probably amount to very nearly as much in value. There are numerous grist and saw mills, carriage factories, paper and powder mills, hardware and cutlery factories, machine shops, manufactories of glass, shoes, wooden ware, &c.—Portsmouth is the only port of entry, and the centre of all the direct foreign commerce of New Hampshire; but the great bulk of the commercial intercourse of the state is carried

on through Boston. In the year ending June 30, 1859, the exports from Portsmouth amounted to \$9,793, and the imports to \$23,227. The entrances comprised 48 vessels of 4,857 tons, 44 vessels and 3,592 tons being foreign, and the clearances 47 vessels of 4,084 tons, 45 vessels and 3,668 tons being foreign. The chief exports of the state consist of manufactured goods, timber, live stock, wool, fish, beef, pork, apples, pot and pearl ashes, and granite. The shipping registered at Portsmouth and belonging to the state in 1859 amounted to 84,485 tons. The steamers which run on Winnepiseogee lake are registered at Portsmouth. In the year ending June 30, 1859, there were 6 vessels built, with an aggregate tonnage of 3,846. The railroads lying wholly or in part in New Hampshire, with their lengths within the state as nearly as can be ascertained, are as follows:

	Miles.
Concord, from Concord to Nashua.....	35
Portland division of Grand Trunk of Canada.....	52
Boston, Concord, and Montreal, from Concord to Haverhill.....	98
White Mountains, from Haverhill to Littleton.....	90
Northern New Hampshire, from Concord to W. Lebanon.....	69
Concord and Portsmouth.....	47
*Concord and Claremont, from Concord to Bradford.....	25
Contoocook River, from Hopkinton to Hillsborough.....	15
Manchester and Lawrence.....	22
Worcester and Nashua.....	8
Nashua and Lowell.....	4
Wilton, from Nashua to Wilton.....	15
*Peterborough and Shirley, from Groton, Mass., to Mason village.....	19
Cheahire, from Fitchburg to Bellows Falls.....	40
Ashuelot, from South Vernon, Vt., to Keene.....	16
Manchester and North Wear.....	19
Cocheoc, from Dover to Alton bay.....	23
*Great Falls and Conway (to Union village).....	30
Boston and Maine.....	34
Eastern, from Portsmouth to Massachusetts.....	13
Sullivan, from Bellows Falls to Windsor, Vt.....	26
Total.....	681

Several short canals, locks, and dams were built in connection with the improvement of the navigation of the Merrimack river, but they have been entirely superseded by the railroads, and are now altogether disused. On Dec. 3, 1860, there were 51 banks, the condition of which was as follows: Liabilities: capital, \$4,981,000; circulation, \$3,332,010; deposits, \$1,284,627.74. Resources: notes, bills of exchange, &c., \$8,794,948.88; specie, \$248,719.77; real estate, \$75,646.74; total, \$9,114,315.39.—The New Hampshire asylum for the insane is said to be one of the best establishments of the kind in the United States. The blind are sent to the Perkins Institution in Massachusetts, and the deaf and dumb to the American asylum in Connecticut. An excellent system of education has been established. The office of school commissioner was abolished in 1850, and the county commissioners of schools now constitute the board of education. The school report for the year ending May, 1859, gives the following statistics. The number of districts was 2,862; of scholars, 86,708; average attendance for the year, 55,606; male teachers 1,104, female 3,184; and 87,808 volumes were in the school, district, or town libraries.

* Unfinished.

In the year 1858, 18 teachers' institutes, attended by 1,901 teachers, were held in the different counties. There are 4 theological, 1 medical, and 107 private schools, and 1 college, Dartmouth, with an income in 1850 of \$11,000. In 1856 a house of reformation for juvenile and female offenders was opened at the "Stark Farm" in the vicinity of Manchester, capable of accommodating 125 boys and 25 females. During the year ending May 31, 1859, 88 convicts were received into the state prison, making a total, with those previously imprisoned, of 148. The receipts and earnings of the institution for the year were \$10,578, and the expenses \$8,247. In 1859, according to the latest reports of the different denominations, there were 700 churches or religious societies, of which 91 were Baptist, 24 Christian, 190 Congregational, 16 Unitarian, 78 Universalist, 14 Episcopal, 127 Freewill Baptist, 15 Friends', 91 Methodist, 8 Presbyterian, 11 Roman Catholic, 2 Shakers', and 88 union and miscellaneous. The value of church property is estimated at more than \$1,500,000. The total number of newspapers in New Hampshire in 1860 was 38, 8 of which were daily. There is one monthly periodical, devoted to education.—The constitution of 1784, amended in 1792, is the fundamental law of the state. The government is vested in a governor, a council composed of 5 members, a senate of 12, and a house of representatives, all to be elected annually. The state is divided into 5 councillor and 12 senatorial districts. The right of suffrage is extended to every male inhabitant 21 years old, who has resided in the town 6 months, excepting paupers, and persons who at their own request are excused from paying taxes. A town having 150 rateable polls may choose one representative, with the allowance of one additional representative for every additional 800 polls. The general election is held on the 2d Tuesday in March, and the official year begins on the 1st Wednesday in June. No person can hold the office of governor, or be a senator or representative in the legislature, unless he conforms to some denomination of Protestantism. The selectmen of towns must submit to the inhabitants once in every 7 years the question of amending the constitution, when if a majority be in favor thereof a convention must be called, and if the amendments are carried by a two-thirds vote when submitted to the people they become law. Since June, 1859, the judiciary consists of a supreme judicial court, with a chief justice and 5 associates; this is now the only state court, excepting justices' and police courts. Terms are held by one or more of the judges twice a year in each county, and in some counties 3 times annually. The state is divided into 4 judicial districts, and for the determination of questions of law 2 terms are held in each annually. The revenue of New Hampshire is derived principally from taxation. For the year ending June 1, 1860, it amounted to \$206,890.89, including a balance in the treasury from

the previous year of \$27,802.60, and a temporary loan of \$42,750. The expenditure during the same year was \$184,445.77, which left a balance to the credit of the state of \$22,444.62. On June 1, 1860, the amount of the state debt was \$82,147.76, from which would have to be deducted the amount in the treasury, some outstanding taxes, and \$15,592 of trust funds.—New Hampshire was first visited by Europeans in 1614, and the first settlement was made near Portsmouth in 1623. The district was several times connected with Massachusetts; it was made a royal province in 1679, but was again joined to Massachusetts in 1689, and was afterward for a little while attached to New York. In 1741 it became a separate province, and remained so till the revolution. The early settlers were greatly annoyed by the Indians until after the English got possession of Canada. In 1689, in revenge for some injuries done them 18 years before, a party of Indians attacked Dover, killed many of the inhabitants, and burned several houses. The settlements of New Hampshire were gradually extended further W. than the original limits prescribed by the patents of the colony, and it was supposed, till 1764, that the territory at present included in Vermont formed part of the province, and grants of land were made in that direction by the authorities. The disputed district was claimed by New York, and a vexatious controversy ensued, which lasted till the independence of Vermont was acknowledged in 1790. In 1776 New Hampshire made a public declaration of independence, and established a temporary government to continue during the war. The state took an active part in the war of independence, and the men of New Hampshire were engaged on every battle field from Bunker hill to the surrender of Cornwallis in 1781. At the battles of Stillwater, Saratoga, Monmouth, and Bennington they were particularly distinguished for their bravery. On June 21, 1788, the state in convention ratified the constitution of the United States, 57 votes being cast for and 46 against it. In 1807 the seat of government was permanently established at Concord. About 1834 a dispute of long standing with the settlers of that part of the state north of lat. 45°, who claimed to be independent of state jurisdiction, led to the military being called out, but order was restored without serious conflict.

NEW HANOVER, a S. E. co. of N. O., bordering on the Atlantic and bounded W. by the Cape Fear river and one of its branches; area estimated at 1,000 sq. m.; pop. in 1850, 17,668, of whom 8,581 were slaves. It has a level surface with occasional swamps, and a not very fertile soil, and contains large forests of pine. The productions in 1850 were 215,488 bushels of Indian corn, 168,002 of sweet potatoes, and 1,413,525 lbs. of rice. There were 6 saw mills, 4 planing mills, 14 turpentine distilleries, 25 tar and turpentine manufactories, 2 ship yards, 6 newspaper offices, 19 churches, and 1,170

pupils attending public schools. It is intersected by the Weldon and Wilmington railroad. Capital, Wilmington.

NEW HARMONY, a town in Posey co., Ind., on the Wabash river, 50 m. from its mouth; pop. estimated at 700. It was built by the Harmonists under George Rapp in 1815, and purchased from them in 1824 by Robert Owen for the purpose of testing his social system, an experiment which resulted unsuccessfully. Mr. Owen sold a large portion to William Maclure, who there established a school of industry, which after a trial of about 6 years was abandoned. After the failure of these various projects the town declined for several years, but is now improving. It contains an Episcopal and a Methodist church, a working men's institute, a large school house, a union hall used as a theatre, 8 steam mills, and 2 distilleries. In 1857 it exported 1,900,000 lbs. of pork, 6,000 bbls. of whiskey, 20,000 bushels of wheat, 150,000 bushels of Indian corn, and 600 head of cattle.

NEW HAVEN, a S. co. of Conn., on Long Island sound, bounded W. by the Housatonic river, and drained by the Naugatuck, Quinepiack, and other streams; area, 640 sq. m.; pop. in 1850, 65,588. The surface is generally uneven, mountainous in the middle and toward the E., and the soil is moderately fertile. On the coast there are several excellent harbors. The agricultural productions in 1850 were 225,881 bushels of Indian corn, 445,125 of potatoes, 112,727 of rye, 107,859 of oats, 67,176 tons of hay, 45,986 lbs. of wool, and 943,915 of butter. There were 11 grist, 6 paper, and 15 saw and planing mills, 12 foundries, 87 boot and shoe and 8 pin manufactories, 18 tanneries, 103 churches, and 10,781 pupils attending public schools. The county is intersected by the Naugatuck, New Haven and Northampton, and New Haven, Hartford, and Springfield railroads; and the New York and New Haven, and the New Haven and New London railroads meet at the capital, New Haven.

NEW HAVEN, a township, city, and port of entry of Connecticut, capital of New Haven co. and semi-capital of the state, situated at the head of New Haven bay or harbor, 4 m. from Long Island sound, and 76 m. E. N. E. from New York, in lat. 41° 18' 28" N., long. 72° 56' 30" W.; pop. in 1850, 22,583; in 1860, not including about 1,300 persons temporarily residing in the city for purposes of education, 39,277, viz.: of the city proper 85,535, of Westville 1,095, and of that part of Fair Haven which lies in New Haven township 2,647. The city stands on a plain about 2 m. wide, and is nearly surrounded by hills from which delightful views may be obtained. Chapel street, the fashionable promenade, extends in a W. N. W. direction throughout the length of the city. The dwelling houses are generally neatly built and surrounded by gardens, and many of them are almost hidden from view among trees. The number of magnificent elms with which the

principal avenues are planted has caused New Haven to be called "the city of elms." They were mostly set out about the close of the 18th century by James Hillhouse, or through his influence and example. Of several public squares which adorn the city, the principal are Wooster square, an enclosure of 5 acres in the E. part, laid out with remarkable elegance and good taste, and the "Green," 16 acres in extent, and shaded by beautiful elms. Brewster's park, adjoining West river and Westville, comprises 55 acres. Works to supply the city with water from Mill river will soon be in operation. Of the public buildings, the first in point of interest are those connected with Yale college. They consist mainly of 8 plain brick structures opposite the public green, occupying nearly a whole square, and a number of other edifices in the rear, one of which, occupied for the library, is a costly fire-proof Gothic building, 150 feet long. (See YALE COLLEGE.) The custom house, near the green, is of Portland stone, and has apartments for the post office and U. S. courts. The state house, hospital, medical college, railroad depot, young men's institute, orphan asylum, and almshouse are the principal other buildings. There are 33 churches, viz.: 3 Baptist, 10 Congregational, 7 Episcopal, 2 Jewish, 6 Methodist, 1 Moravian, 3 Roman Catholic, and 1 Universalist. The New Haven burying ground, containing 18 acres, is beautifully laid out on the N. W. of the city. The Evergreen cemetery, on West river, is large and tastefully adorned, and near it is a Catholic burying ground. The educational establishments, beside the college, comprise a number of good private seminaries for both sexes, and a system of public schools. There are 8 banks with an aggregate capital of \$3,457,000; 3 savings banks with deposits to the amount of \$3,000,000; 4 fire and marine insurance companies (capital \$650,000); 1 mutual life insurance company (capital \$250,000); 4 daily newspapers, and several monthly and other magazines. A capital of \$4,016,965 is invested in manufactures, which give employment to 7,222 persons, and produce \$8,722,642 worth of goods annually. The motive power is steam. An important manufacture is that of clocks, which are made here very extensively, and are exported to the most distant countries. Carriage making is more largely carried on than in any other part of New England, as many as 13,726 vehicles, valued at \$2,228,460, being turned out annually, chiefly for the southern market. Iron working, particularly in the lighter and more valuable products of that metal, and the manufacture of boots, shoes, shirts, and other articles of clothing and India rubber goods are also prominent branches of industry.—The harbor of New Haven is shallow, and has extensive oyster beds; and the main channel from the junction of Quinepiack and Mill rivers is somewhat circuitous, and not of sufficient depth for large vessels. To meet the channel from the business part of the city a wharf 3,500 feet in length

has been built, and there are other landings for steamboats. Ship building is almost confined to Fair Haven. Apart from the coasting trade, the chief commerce is with the West India, a large proportion of the West India trade of all New England being conducted by New Haven merchants, which the U. S. commercial reports do not fully exhibit, as much of their business is done through New York. During the year ending June 30, 1859, the imports were \$1,108,388, and the exports \$954,789. The entrances were 182 vessels, of 27,916 tons; the clearances 118 vessels, of 23,154 tons; and the aggregate tonnage of the district, June 30, 1859, was 23,751. New Haven has regular communication by steamboats with New York, and railroad connection with all parts of the Union by means of the New York and New Haven, the New Haven, Hartford, and Springfield, the New Haven and Northampton, and the New Haven, New London, and Stonington railroads. —New Haven was settled in 1688 by a company chiefly from London under Theophilus Eaton, their first governor, and the Rev. John Davenport. It was a distinct colony until 1664, when after a protracted struggle it was united with Connecticut under the charter of 1662. It was incorporated as a city in 1784.

NEW HEBRIDES, a group of volcanic islands in the S. Pacific ocean, N. E. of New Caledonia, between lat. 18° 15' and 20° 3' S., and long. 166° 30' and 170° E.; area estimated at 2,500 sq. m.; pop. about 200,000. Beside a great number of islets and rocks, they comprise about 20 islands of considerable size, the most important of which are Espiritu Santo, 70 m. long by about 25 m. broad; Mallicollo, 60 m. long by 28 m. broad, with a good harbor called Port Sandwich, in lat. 16° 25' S., long. 167° 46' E.; Erromango, Tanna, Ambrim, Annatom, Aurora, Banks, Sandwich, and Whitsuntide. There is an active volcano in Tanna. Most of these islands are hilly, and there are some high mountains. With the exception of Erromango, and some of the smaller, they are all well wooded and supplied with good water, and present a most luxuriant vegetation. Sandal wood and ebony are procurable. Yams, taro, shad-docks, bananas, limes, cucumbers, cocoanuts, and a species of sweet potato are cultivated. There are few animals; the most remarkable is a diminutive species of hog, which when full-grown is not larger than a rabbit. The natives are of the same race of oriental negroes that are found on New Guinea and other islands in the vicinity; they are courageous, active, and hospitable, but are accused of cannibalism. In point of intelligence they are below the natives of most of the South sea islands; their habits are disgusting, their persons filthy, and their faces smeared with turmeric and charcoal. The use of betel nut and chunam is common throughout the group; and the language is said to possess a similarity to the Malay. They have no canoes, and use a sort of raft, on which they only venture a few hundred yards

from the shore.—Quiros in 1606 was the first to discover any portion of this group. He saw the N. and largest island in the group, and concluded that it must be a portion of the long sought southern continent, which he named Australia del Espiritu Santo; but he made no explorations to satisfy himself that his conjecture was well founded. He speaks of it only as one land, and it is described as abounding in gold, silver, and pearls. Bougainville, 162 years later, saw that the N. part was composed of several islands, to which he gave the name of the Great Cyclades. Cook discovered the greater part of the S. chain in 1778, and called the islands collectively the New Hebrides; and as his discovery much exceeded in extent those previously made, the name given by him has superseded that applied by Bougainville. Erromango has acquired a melancholy notoriety from the massacre of the well known missionary the Rev. John Williams, author of "Missionary Enterprises."

NEW HOLLAND. See AUSTRALIA.

NEW IRELAND, an island in the S. Pacific ocean, between lat. 2° 40' and 4° 52' S., and long. 150° 30' and 152° 50' E. It is separated from New Britain on the S. W. by St. George's channel, and from New Hanover on the N. W. by Byron's straits; length about 200 m., average breadth 12 m. The hills rise to the height of 1,500 or 2,000 feet, and are clothed from base to summit with the most luxuriant forest trees. The timber grows to a great height, many of the trees being 80 or 90 feet, perfectly straight, and 9 feet in circumference. The indentations of the coast offer several very snug harbors. The lower tracts are well cultivated, and produce sugar cane, bananas, cocoanuts, yams, and numerous other plants and trees. The inhabitants are oriental negroes, and are remarkable for the cleanliness of their villages. Their canoes are neatly formed, but not very large. Dogs, pigs, and turtles are the chief animals. The island produces for commerce fancy woods and tortoise shell, the latter of superior quality.

NEW JERSEY, one of the 13 original states of the American Union, situated between lat. 38° 55' and 41° 21' N. and long. 73° 58' and 75° 29' W.; extreme length 167 m., extreme breadth 96 m.; area estimated at 8,320 sq. m., or 5,324,800 acres. New Jersey is bounded N. and N. E. by the state of New York, from which it is separated on the N. E. by the Hudson river; E. by New York bay and the Atlantic ocean; S. by the Atlantic and Delaware bay; and W. by the states of Delaware and Pennsylvania, from which it is separated by the Delaware river. The state is divided into 21 counties, viz.: Atlantic, Bergen, Burlington, Camden, Cape May, Cumberland, Essex, Gloucester, Hudson, Hunterdon, Mercer, Middlesex, Monmouth, Morris, Ocean, Passaic, Salem, Somerset, Sussex, Union, and Warren. Trenton, situated on the Delaware at the head of steam navigation, is the capital. Several railroads

and the Delaware and Raritan canal have their termini here. Newark is the largest city in the state, and its inhabitants are principally engaged in manufactures. The other most important cities and towns are Paterson, New Brunswick, Camden, Jersey City, Hoboken, Burlington, Princeton, Hackensack, Morristown, Gloucester, Elizabethtown, Rahway, Freehold, Mount Holly, Bordentown, and Salem. The population of New Jersey in 1790 and at subsequent periods was as follows:

Years.	Whites.	Free colored.	Slaves.	Total.
1790.....	169,954	2,769	11,438	184,161
1800.....	195,195	4,402	12,493	211,949
1810.....	222,861	7,345	10,551	240,555
1820.....	257,409	13,809	7,557	278,775
1830.....	300,396	18,306	3,254	321,956
1840.....	351,568	21,044	674	373,286
1850.....	465,509	28,510	286	494,305
1855.....	509,499
1860.....	675,513

Density of population to the square mile in 1850, 58.84; in 1860, 81.24. In 1850 there were of white inhabitants 233,440 males and 232,069 females; of the free colored, 11,800 were males and 12,010 females; and of slaves, 108 were males and 128 females. Deaf and dumb, 189; blind, 207; insane, 379; idiotic, 419. Births, 13,556; marriages, 3,719; deaths, 6,454. Number of families, 89,060; of dwellings, 81,064. Of the white population, 861,691 were born in the state, 43,711 in other parts of the Union, 81,092 in Ireland, 11,877 in England, 2,362 in Scotland, 166 in Wales, 581 in British America, 10,686 in Germany, 943 in France, and 1,785 in other countries, or in places which could not be ascertained. Of the whites, 27 per cent. were under 10 years of age, 22.60 between 10 and 20 years, 18.33 between 20 and 30, 12.68 between 30 and 40, 8.71 between 40 and 50, 5.55 between 50 and 60, 3.21 between 60 and 70, 1.41 between 70 and 80, 0.44 between 80 and 90, 0.04 between 90 and 100; and of 0.08 per cent. the ages were unknown. Of 128,748 males over 15 years of age, there were employed in commerce, trade, manufactures, mechanic arts, and mining, 46,545; agriculture, 82,884; labor not agricultural, 86,883; sea and river navigation, 4,851; law, medicine, and divinity, 1,781; other pursuits requiring education, 2,457; government civil service, 378; as domestic servants, 404; and in pursuits not specified, 1,668. The state is entitled to 5 representatives in congress.—New Jersey has a direct coast line of 120 m., but including bays, islands, and other irregularities, the coast measures 540 m. On the N. E., Raritan, Newark, and New York bays, and the Hudson river, form good harbors for large vessels; but between Sandy Hook and Cape May there is a long stretch of sandy beach, intersected here and there by inlets, and enclosing long shallow lagoons. Barnegat bay and inlet, Little Egg harbor, Absecon inlet, and Great Egg harbor are the principal openings for shipping. Many of the ports

which were on this part of the coast at the time of the settlement of the country have been filled up by silt, and others formed; and as the Atlantic surf beats here with unrestrained violence, there are frequent disastrous shipwrecks. The New Jersey shore of Delaware bay consists chiefly of a strip of salt marsh, destitute of harbors. On the Delaware river the land is more elevated. Beside the Hudson and Delaware, already mentioned as forming part of the E. and W. boundaries of the state, the interior is watered by several streams, the most important of which are the Passaic and Hackensack, flowing into Newark bay; the Raritan, falling into the bay of the same name; Maurice river, whose mouth is in Delaware bay; and Great Egg Harbor river, which flows into the Atlantic ocean. These rivers are all navigable for vessels of light draught for distances varying from 10 to 20 m. from their mouths. A number of small streams fall into the Delaware river, but they are not navigable.—The surface of the N. part of the state is hilly and mountainous. The Blue Ridge lies on the N. W. boundary, and a short distance S. of it several parallel ranges of the Alleghany system cross the state in a N. E. direction from Pennsylvania into New York. They bear the local names of Schooley's, Trowbridge, Ramapo, and Second mountains. In the N. E. there are some remarkable elevations, including the Palisades, a range of trap rocks on the Hudson river, in Bergen co., which extend for about 15 m. along the river, with a height of from 200 to 500 feet; and the Neversink hills, a group between 300 and 400 feet high, just below Raritan bay. Elsewhere the surface is generally low and level, except on the banks of the Delaware above Trenton. The whole state S. of a line drawn N. E. from this point to the Neversink hills is an extended plain, nowhere rising more than 60 feet above the sea.—New Jersey is separated into 5 distinct geological divisions, each of which is clearly defined by its peculiar formations, mineral products, and soil. Each has its special objects of interest and value, and all combine to make the state one of the most interesting as presenting so clear a succession of different geological groups, which are also most important for the value of the minerals and ores they contain. The geological formations cross the state in belts from N. E. to S. W. The broadest of these is the most southern one, occupying all the counties on Delaware bay and along the Atlantic coast as far N. as Shark inlet in Monmouth co., and extending inland to a line drawn from this inlet to Salem on the Delaware. The region thus included is a sandy plain covered with forests of pitch pine and oak, and cedar swamps. It is watered by numerous streams, some of which flow into the Atlantic and some into the Delaware. Along the course of two of these are found extensive deposits of bog iron ore, which have supplied 6 or 7 blast furnaces in their own vicinity, beside furnishing large quan-

titles of ore for shipment to other localities. In the last century and the early part of the present, iron ores were transported to furnaces in Plymouth co., Mass., situated in a similar but less important district of bog ores. The streams referred to are the Atsion and Wading and their branches, which unite and flow into the Little Egg Harbor river. On the Atsion and its tributaries the ores spread over an area of 20 m. by about 3 in breadth; and the deposits on the Wading were almost as extensive, though not as productive. A number of other smaller deposits occur along the N. W. margin of the region. Calcareous marls of the miocene period are found in the W. part of Cumberland co., and make the northern outcrop of this formation, which further S. extends through the Atlantic states, and furnishes immense quantities of shelly remains for agricultural uses. In the same county an abundance of good sand for glass making is found, and worked at the glass houses at Millville. There are several other localities of similar sand in this region, and a number of establishments for making glass, one of which is in its extreme N. E. portion. The next formation, coming up from beneath the more recent sands of the coast, is the upper secondary group of alternating sands and clays, known as the greensand or marl district. Excepting a few rare occurrences of a brown sandstone and of a yellowish limestone, filled with remains of coral, a great variety of shells, &c., the mineral beds are wholly formed of loose unconsolidated materials. Numerous beds of valuable greensand (see GREENSAND) are found throughout this district, and add much to its fertility; and it contains some of the finest agricultural lands in the state. The surface is gently undulating and drained by numerous streams, which flow into the Delaware. The Camden and Amboy railroad lies wholly along the range of this formation, and from Amboy to Bordentown generally 4 to 5 m. from its N. W. boundary. In this district are found the great beds of plastic clay, which are extensively worked near Amboy and at other localities for the manufacture of fire brick.—The next formation should be the great belt of metamorphic rocks which extends from Canada through Vermont and the Atlantic states, and should take in nearly all of northern New Jersey in its range. Its S. margin indeed appears at Trenton, and extends a few miles directly toward the outcrop of the same margin of the formation on the N. side of Staten island, and along New York island; in the other direction the same group spreads out toward Philadelphia and Norristown in Pennsylvania. But from the margin of the greensand formation in New Jersey toward the N. W., the metamorphic group is overlaid and concealed by the red sandstone of the middle secondary. The strata of argillaceous red sandstone which make this formation dip gently toward the N., and occupy a basin of 20 m. in width, which extends from the Hudson

river below the highlands S. W. through the middle Atlantic states. This is the region of the red rocks and red sandy soil of New Jersey. Perth Amboy, New Brunswick, Princeton, and Trenton are near its S. E. margin, and its N. W. border follows up the Ramapo from the New York state line to Pompton, and thence on the same course by the S. E. foot of Trowbridge mountain, Mine mountain, and Musconetcong mountain, past New Germantown to Spring Mills on the Delaware. The district is a moderately undulating plain, diversified by numerous abrupt and rugged hills and long narrow ridges with very steep and rocky sides, which are composed of greenstone trap. The longest of these ridges skirts the Hudson river on the W. side and forms the Palisades, and, continuing back of Jersey City, terminates in New York bay. Through this ridge the Bergen tunnel at Hoboken was completed in 1860. The copper ores of New Jersey (see COPPER MINES) occur near the line of contact of the sandstone with these greenstone ridges.—The fourth geological group is that of the metamorphic rocks, occupying the region of the highlands, which are a continuation of those from New York. On the New York line the gneissic rocks are largely developed from the Ramapo to Pochuck mountain, where the lower silurian limestone begins to appear in the valleys extending S. W. between the parallel ridges of gneiss and metamorphic slates. The limestones increase in proportion toward the S. and the W., running in continuous lines with the valleys across this portion of the state. Along this belt are found the great beds of magnetic and specular iron ores (see IRON) which have long given support to the important iron establishments of this state, the principal seats of which are at Boonton, Ringwood, Dover, Rockaway, and Phillipsburg. The great blast furnaces at the last named place on the Delaware are supplied, as are also many of the furnaces in the Lehigh valley, Penn., with the rich primary ores of northern New Jersey, brought to the Delaware by the Morris canal; and by the same route are returned to the furnaces in the vicinity of the iron mines the anthracites of Pennsylvania. In the limestone at Franklin, near its contact with the gneiss, are found the beds of red oxide of zinc associated with the iron ore called franklinite, for an account of which see FRANKLINITE and ZINC. This locality is on the westernmost border of the metalliferous district, which may be bounded by a line extending from Pochuck mountain to Belvidere on the Delaware. Beyond this succeed the formations belonging to the lower portion of the Appalachian system of rocks. The lower silurian limestones gradually give place to a belt of the Hudson river slates, which reaches as far W. as the Water Gap on the Delaware, to the base of a high ridge of coarse white sandstone, the continuation of the Shawangunk mountain and of its peculiar grit rock, stretching in an almost un-

broken ridge nearly from Rondout on the Hudson across the N. W. margin of New Jersey into Pennsylvania. On the N. W. side of this ridge, between its base and the Delaware, which forms the boundary of the state, appear in succession a long strip of the red sandstone of the Clinton group, and then the limestone of the upper Helderberg group, filling the valley of the river.—New Jersey offers numerous attractions to travellers, among which are the falls of the Passaic near Paterson; the passage of the Delaware through the Blue mountains, called the Delaware Water Gap; the well known bathing places of Cape May, Long Branch, Deal, Squan beach, Absecon beach, and Tuckerton; Schooley's mountain in Morris co., with a mineral spring on its summit; and Brown's Mills, among the pines, 20 m. from Burlington, a favorite resort for valetudinarians.—The climate varies much in different parts of the state. In the N., where the country is more elevated, it is much colder than toward the S., where the influence of the ocean and a low situation is felt. Fevers and ague prevail in the neighborhood of the marshes, but upon the sea shore and in the hilly regions the climate is remarkably healthy.—Portions of the soil of the great plain of southern and central New Jersey are not naturally fertile; but by the application of marl and other fertilizers the soil is rendered very productive. In certain localities, however, particularly near the sea coast, the soil consists of white sand, and is not capable of much improvement; but even on the coast there is some arable land, and Long Branch and Deal beaches are said to be the only fertile spots immediately on the Atlantic from Maine to Georgia. The N. part of the state is well adapted to cultivation and pasturage. Excellent grazing lands are found among the hills, while the alluvial valleys are highly productive.—The vegetation presents no remarkable features, being similar to that of the central states generally. In the N. are found the oak, hickory, and other forest trees, and in the S. are valuable pine woods, cedar swamps, and a considerable growth of stunted oaks, which, though useless for building purposes, make excellent fuel. The central region is the most thoroughly improved part of the state, and forms a vast market garden from which New York and Philadelphia are in large part supplied. The apples and cider of this locality are famous, and the peaches of the more southerly section are excellent in quality and abundant. Muskmelons, watermelons, sweet potatoes, Irish potatoes, Indian corn, wheat, rye, oats, hay, flax, grass seed, plums, apricots, and cherries are raised; beeswax, honey, and butter are made; and there is also a limited production of barley, tobacco, wine, silk, maple sugar, and hops. Several of the native wild animals, such as the wolf, bear, and deer, are still seen in the forests.—In 1850 New Jersey contained 28,905 farms, valued at \$120,287,511, and comprising 1,761,991 acres of improved and 984,955 of unim-

proved land; value of implements and machinery thereon, \$4,425,508. The live stock consisted of 68,955 horses, 4,089 asses and mules, 118,786 milch cows, 12,077 working oxen, 80,455 other cattle, 160,488 sheep, and 250,870 swine; value, \$10,679,291; value of animals slaughtered in the preceding year, \$2,688,552. The products of agriculture for the year ending June 1, 1850, were 1,601,190 bushels of wheat, 1,255,577 of rye, 8,878,068 of oats, 8,759,704 of Indian corn, 6,492 of barley, 878,984 of buckwheat, 8,207,286 of potatoes, and 508,015 of sweet potatoes; hay, 435,950 tons; clover seed 28,280, and other grass seeds 68,051 bushels; flax seed, 16,525 bushels; flax, 182,965 lbs.; hops, 2,183 lbs.; butter, 9,487,210 lbs.; cheese, 865,756 lbs.; peas and beans, 14,174 bushels; value of market garden products, \$475,242, and of orchard products \$607,268; beeswax and honey, 156,694 lbs.; tobacco, 156,692 lbs.; wool, 375,896 lbs.; silk cocoons, 28 lbs.; wine, 1,811 galls. The total value of agricultural products in 1850 was \$19,822,894, and of home-made manufactures \$112,781.—The abundant water power of New Jersey, and its facilities of communication with the great commercial cities of the Union by railroads, canals, and rivers, have greatly developed its manufactures. In 1850 there were 4,108 establishments engaged in mining, manufactures, and the mechanic arts, employing a capital of \$22,184,780, and 87,311 hands (38,549 males and 8,762 females), paying in wages \$9,202,788 annually, using \$21,992,186 worth of raw material, and manufacturing annually \$39,718,586 worth of goods. The principal establishments were 21 cotton mills, 41 woollen mills, 10 manufactures of pig iron, 45 of iron castings, 64 of wrought iron, 68 distilleries and breweries, and 183 tanneries. There are numerous manufactories of machinery, locomotives, carriages, saddlery and harness, jewelry, glass, pottery, bricks, paper, small arms, paint, boots and shoes, and hats. The fisheries in the neighboring waters are a source of great profit, particularly those of oysters and shad.—It is difficult to estimate the foreign trade of the state, because Jersey City, which has a large direct trade with foreign countries, is included in the collection district of New York, and much of the rest of the commerce is transacted through Philadelphia. The chief ports represented in the official returns are Newark and Perth Amboy. There are 5 others, engaged principally in the coasting trade. The registered tonnage, June 30, 1859, was 119,616, and the tonnage of the shipping built during the previous year was 5,562. The exports were valued at \$21,988, and the imports at \$5,046. The entrances were 2 American vessels of 256 tons, and 23 foreign of 3,084 tons—total, 25 vessels, 3,340 tons; the clearances were 6 American vessels of 2,322 tons, and 13 foreign of 1,809 tons—total, 19 vessels, 4,131 tons. The internal traffic is much more important, and the state has a vast transit business, lying as it does on the direct land route between the

North and South. It is traversed by numerous railroads, the names of which, with their present termini and number of miles in running order within the state, as nearly as can be ascertained, are as follows:

	Miles.
New York and Erie, from Jersey City to Dunkirk.....	83
Branch from Jersey City to Paterson.....	17
Northern New Jersey, from Jersey City to Piermont ..	94
Newark and Bloomfield.....	6
New York and Philadelphia, from Jersey City to Camden	96
New York and Philadelphia, via Camden and Amboy, from South Amboy to Camden.....	62
Branch from Burlington to Mount Holly.....	6
Central New Jersey, Jersey City to Easton, Penn.....	75
Freehold and Jamesburg Agricultural.....	11
Morris and Essex, from Newark to Hackettstown.....	58
Sumner, from Newton to Waterloo on the Morris and Essex.....	19
Camden and Atlantic, from Philadelphia to Atlantic City	61
Belvidere Delaware, from Philadelphia to Belvidere ..	94
Branch from Lambertville to Flemington.....	19
Delaware, Lackawanna, and Western, from New Hampton to Ithaca, N. Y.....	98
West Jersey, from Camden to Cape May, completed as far as Woodbury.....	10
Raritan and Delaware bay, from Port Monmouth to Long Branch.....	20
Total miles within the state.....	611

The Morris canal connects Easton, Penn., with Jersey City, and has a large business in conveying coal from Pennsylvania to New York. The Delaware and Raritan canal extends from Bordentown and Trenton on the Delaware to New Brunswick on the Raritan, and affords inland water communication between New York and Maryland.—On Jan. 1, 1860, the state had 46 banks, the condition of which was as follows: Liabilities: capital, \$7,884,412; circulation, \$2,876,171; deposits, \$5,770,584; profits on hand, \$1,387,778. Resources: notes, bills of exchange, &c., \$16,581,987; specie, \$940,701; real estate, \$446,202; total, \$17,918,890. The principal public institutions supported wholly or in part by the state are the lunatic asylum at Trenton, which was opened in 1848, and in 1858 had 279 patients, and the state prison, also at Trenton, which in 1858 contained 285 convicts.—The school officers' report for 1858 gives returns of 1,651 public schools (16 townships made no returns), and 2,103 teachers (1,235 males and 868 females). The whole number of children taught was 188,548; the average price of tuition per quarter to each pupil was \$1.29, and the whole amount appropriated for common school purposes was \$526,572.17, of which \$388,160.06 was raised by special tax, \$86,078.81 received from the state, \$40,820.17 received from other sources, and \$61,518.68 raised in addition to the regular income for building, repairing, and furnishing school rooms. The receipts of the school fund during the year amounted to \$78,885.72, including a balance left over from the previous year. The management of the fund and maintenance of the schools are confided to a board of trustees consisting of the governor, secretary of state, attorney-general, president of the senate, and speaker of the house of assembly. A normal school was established in Feb. 1855, for 5 years, and in

1859 the term was extended another 5 years. It is situated in Trenton, and in Jan. 1859, had 118 pupils and 146 alumni. Connected with it are a model school with 800 pupils, taught by the members of the senior class in the normal school, and the Farnum preparatory school, founded in 1857, and having 120 pupils in 1859. The latter is situated at Beverly, Burlington co. In 1850 there were 77 public libraries in the state, containing 48,908 volumes. The chief collegiate institutions are the college of New Jersey at Princeton, Burlington college at Burlington, Rutgers college at New Brunswick, Seton Hall Roman Catholic college near Madison, the theological seminary of the Reformed Dutch church at New Brunswick, and the theological seminary of the Presbyterian church at Princeton. A plan has lately (1860) been formed for establishing at Burlington, under the auspices of the presbytery of Burlington, an institution for educating, as far as possible gratuitously, the children of foreign missionaries and those preparing for the ministry. According to the census of 1850, New Jersey contained 814 churches, with accommodation for 845,788 persons, and property valued at \$3,540,486. Of these churches, 108 were Baptist, 8 Christian, 8 Congregational, 52 Episcopal, 7 free, 52 Friends', 7 Lutheran, 312 Methodist, 149 Presbyterian, 64 Reformed Dutch, 28 Roman Catholic, 2 Tunker, 5 union, 2 Unitarian, 8 Universalist, and 10 minor sects. The number of periodicals in 1850 was 51, circulating 4,098,678 copies annually. Of these, 6 were issued daily, 48 weekly, and 2 semi-monthly; 6 were literary and miscellaneous, 1 neutral and independent, and 44 political.—The present constitution of New Jersey was adopted in Aug. 1844, and came into operation on the 2d of the following month. It secures the right of voting to every white male citizen of the United States, 21 years of age, who has resided in the state 1 year and in the county 5 months next preceding the election. The general election is held annually on the 1st Tuesday in November, and all votes are taken by ballot. The legislature consists of a senate of 21 members, one from each county, elected for 3 years, $\frac{1}{3}$ every year, and an assembly of 60 representatives elected annually. The chief executive officers are the governor (salary \$1,800 and fees), elected by the people for 3 years; secretary of state (salary \$500 and fees), appointed by the governor with the advice of the senate; treasurer (salary \$1,000 and fees), elected by the legislature on joint ballot for one year; and the superintendent of schools (salary \$500), appointed by the trustees of the school fund for 2 years. Senators and representatives receive during the session of the legislature \$2 a day for the first 40 days, and \$1.50 a day afterward. The president of the senate and speaker of the assembly are paid \$4 a day for the first 40 days, and \$2 a day afterward. The judiciary consists of a court of errors and appeals, court of chancery, supreme court, courts of com-

mon pleas, orphans' courts, courts of general quarter sessions of the peace, circuit courts, and courts of oyer and terminer. The court of errors and appeals is composed of the chancellor, the judges of the supreme court, and 6 other judges appointed by the governor. They receive \$5 a day for each day's attendance. The governor, chancellor, and 6 judges of this court constitute the pardoning power. The chancellor is appointed by the governor and senate for 7 years, and holds a court of chancery 3 times annually; salary \$2,500. The supreme court consists of 7 justices, appointed for 7 years from each of the 7 judicial districts. They hold circuit courts and court of oyer and terminer 3 times a year in each county, and are *ex officio* judges of the court of common pleas, orphans' court, and court of general quarter sessions of the peace of the several counties. They receive salaries of \$2,000 each, except the chief justice, who receives \$2,100. Judges of common pleas, not exceeding 3 in each county, are also appointed by the legislature for 5 years, and hold court 3 times a year in each county. They are paid \$2 a day for each day's attendance.—The revenue of the state in 1858 amounted to \$315,458.46, including a balance of \$3,058.52 from the preceding year, and the expenditures to \$302,412.88, leaving a balance in favor of the state of \$18,046.08. The principal sources of revenue are transit duties on railroads and canals (\$111,581.92), taxes on capital stock (\$69,969.36), and dividends on railroad and canal stocks owned by the state (\$16,000). Of the expenditures, \$181,431.86 was for ordinary expenses, and \$70,970.52 for extraordinary purposes. The public debt on Jan. 1, 1859, was \$95,000; annual interest on the same, \$5,700; value of productive property owned by the state, \$275,528.35; value of property not now productive, consisting of surplus revenue lent to the counties without interest, \$764,670.60; amount of school fund (including \$11,169.85 unavailable), \$448,924.35.—The precise date of the first settlement of New Jersey is not ascertained. The earliest colony was probably planted at Bergen, between 1617 and 1620, by the Dutch of New Amsterdam, who claimed the whole country as a part of the New Netherlands. In 1623 a Dutch company under Cornelis Jacobson Mey and Adriaen Joriss built Fort Nassau on the E. shore of the Delaware, a few miles below the present site of Philadelphia. Godyn and Bloemart in 1630 purchased land of the Indians at Cape May, but made no settlement. Sir Edmund Ploeden obtained a grant of the country on the Delaware from the king of England in 1634, and called it New Albion; and in 1638 a small party of Swedes and Finns purchased land in the same region from the natives, and planted several settlements. The New Haven colony also made purchases along the Delaware about the same time, but it is not certain that they actually effected a settlement. The Dutch and Swedes afterward drove out all the English

colonists, and in 1655 the Dutch under Peter Stuyvesant, governor of the New Netherlands, dispossessed the Swedes and sent most of them back to Europe. In 1664 Charles II. of England, disregarding the claims of both parties, granted all the territory between the Delaware and Connecticut rivers to his brother the duke of York, and sent an expedition to take possession of it. New Amsterdam was first conquered, the New Jersey settlements at once submitted, and under the authority of Nicholls, the commander of the expedition and first governor, a patent was granted to immigrants from Long Island and New England. Elizabethtown, Newark, Middletown, and Shrewsbury were now founded. In the mean time, however, the duke of York had sold his claim to Lord Berkeley and Sir George Carteret; they named the tract New Jersey in honor of Sir George, who had been governor of the island of Jersey, and had held it for King Charles in his contest with the parliament. They formed a constitution for the colony, and in 1665 sent out Philip Carteret, brother of Sir George, as governor. He fixed the seat of government at Elizabethtown, and by liberal offers to settlers promoted the growth of the country; but his administration was unpopular, the persons who held under Nicholls's patent refused to pay him rent, and in 1670 the people revolted and chose James Carteret, an illegitimate son of Sir George, for their governor. Philip Carteret, however, obtained several concessions and promises from the proprietors, which induced the people to submit again to his authority. The first legislative assembly of New Jersey, which had been held under his proclamation in May, 1668, passed a bill of pains and penalties remarkable for its extreme severity, the punishment of death being assigned for no fewer than 12 offences. In March, 1673, Berkeley sold his interest in the proprietorship to John Fenwick and Edward Byllinge, Quakers. In July of the same year the Dutch recaptured New York, and the surrounding country, including the whole province of New Jersey, at once fell into their hands. New Jersey was called by them Achter Kol. It reverted to Great Britain by the treaty of 1674, and the question now arose whether the title returned to the proprietors or the king. To avoid all difficulty, the king recognized the claim of Carteret, and made a new grant to the duke of York, who also executed a fresh conveyance to Carteret, covering however only a part of the original territory of New Jersey. But before making this conveyance, the duke had included the province in a commission given to Sir Edmund Andros, governor of New York, who refused to recognize the authority of Governor Philip Carteret, arrested all magistrates who would not submit to his own jurisdiction, and finally, on April 30, 1680, carried Carteret himself prisoner to New York. The duke was at last prevailed upon to acknowledge the claims of the proprietors, and

in 1681 the government of Andros came to an end. In the mean time Fenwick and Byllinge, to whom Berkeley had sold his share in the province, conveyed an interest in it to William Penn and two other Quakers, Garven Lawrie and Nicholas Lucas; and Fenwick in 1675 established a Quaker settlement at Salem, near the Delaware. He claimed authority as chief proprietor over all that part of New Jersey S. W. of a line drawn from Little Egg harbor to a point on the Delaware in lat. 41° N.; and the province continued for some years to be divided into East Jersey, subject to Sir George Carteret and his heirs, and West Jersey, under Fenwick and his associates. In Feb. 1682, the whole territory was purchased by William Penn and 11 other Quakers. The first governor under the new proprietors was Robert Barclay, a Scotchman, and one of the 12 purchasers, under whom the country became an asylum for the oppressed members of his creed, and for a time enjoyed great prosperity. But the number of proprietors, the frequent subdivisions and transfers of shares, and various other difficulties in the way of good government, soon involved the province in trouble; and in 1702 the proprietors surrendered the right of government to the crown. Queen Anne appointed Lord Cornbury governor of New York and New Jersey, but each continued to have a separate assembly. In 1708 New Jersey petitioned for a distinct administration, and Lewis Morris was appointed governor. The population was then about 40,000. Until the revolution New Jersey was the scene of no important event, and it was never much exposed to the ravages of the Indians. The last royal governor was William Franklin, the natural son of Benjamin Franklin. A state constitution was adopted in 1776, and throughout the revolution the country was frequently the theatre of war. The battles of Trenton, Princeton, Millstone, Red Bank, and Monmouth were fought on its soil. The first legislature met at Princeton in Aug. 1776, and chose William Livingston governor. The federal constitution was adopted by a unanimous vote, Dec. 18, 1787. The state capital was established at Trenton in 1790.

NEW JERSEY, COLLEGE OF. See PRINCETON.

NEW JERUSALEM CHURCH, a religious body which holds the doctrines set forth in the theological works of Emanuel Swedenborg. These doctrines teach emphatically the oneness of God in essence and in person, and that he is a Divine Man. All life is of love; and God alone has life in and of himself. He is essential love, and thus essential life. All other beings are recipients of life from him. God is also essential wisdom; his wisdom being the form and manifestation of his love, and the means by which it operates. All the works of creation have relation to these two attributes, or to what is good and what is true. Man, being created in the image and likeness of God, has two faculties: a will to receive and be affected

by the divine love, and an understanding to receive and be enlightened by the divine wisdom. In the heavens, where God is perceptibly present, the proximate divine sphere appears to the angels as a sun, from which there is a constant emanation of spiritual heat and light. The spiritual heat is, in its essence, love; and the spiritual light is, in its essence, wisdom; and the hearts of the angels are filled with love, and their understandings illustrated with truth, at the same time that their bodies are warmed and their eyes are enlightened by the heat and light of the spiritual sun. The same influence is operating on men in the natural world. It is from this influence, constantly exerted, that all power of loving and willing, and of perceiving and thinking, is derived.—In the primeval state of man, which in the Sacred Scriptures is represented by the term Adam, the divine influence was received into the will and understanding without being corrupted or perverted by actual or hereditary evil. Divine truth was inscribed directly on the heart. The natural objects by which men were surrounded were to them full of spiritual meaning and significance, and were thus a source of constant delight and instruction. It was also permitted to them to be consciously present in the spiritual world, and to have open communication with the angels of heaven. They constantly perceived and acknowledged that all their love and all their intelligence or wisdom were from the one only source of love and wisdom. But an essential part of their nature was freedom; and, being free, they had the power of averting themselves from the only source of genuine love and life. This aversion, which is represented by the fall of Adam, took place more and more through successive generations, till at length men ceased to regard God as the only source of their life, and imagined that they lived of and from themselves, thus making themselves gods. In this way evil was introduced into the world, and has been transmitted from generation to generation; for the spiritual part of the child, as well as the material, is derived from his parents, and partakes of their quality; the internal being from the father, which by conception is clothed with a corresponding external nature from the mother. The will having become corrupted, men have inherited tendencies to all the evils forbidden in the decalogue. These evils become sins only when they are indulged and committed; but they must be seen and renounced by repentance, reformation, and regeneration, before a state of heavenly life and happiness can be attained.—When mankind had thus fallen, the divine love prompted and the divine wisdom provided the means of their redemption and restoration. It was foreseen and foretold that Jehovah would come into the world to seek and to save that which was lost. All his providential dealings with men looked to this great event, which in the fulness of time was accomplished. But, in order to see the

necessity of the advent of Jehovah into the world, it is important to understand the relation between the spiritual world and the natural world, and something of the condition of both at the time at which this event took place. The spiritual world exists within the natural, as the soul within the body. There is the most intimate relation and connection between the two. Man, as to his soul, is a spirit actually existing in the spiritual world, and is most closely associated with the inhabitants of that world. Their influence is as necessary for his mind, as the heat and light and surrounding atmosphere are for his body. If it should be wholly withdrawn from him, he would at once be deprived of his spiritual faculties, and indeed of life. The spiritual world consists of the heavens, of which there are three, one within, or one higher and purer than the other; of the hells, of which there are also three, standing in direct opposition to the heavens; and of an intermediate place or state between the heavens and the hells, called by Swedenborg "the world of spirits," which is understood by the great gulf spoken of in Luke xvi. Of the three heavens, the highest is called by Swedenborg heavenly or celestial; the middle, spiritual; and the lowest, natural. The heavenly heaven is governed by love, and essentially by love to the Lord; the spiritual heaven by truth, which manifests itself and operates through love to the neighbor; in the natural heaven these loves still govern, but less perfectly, and in a very subordinate degree. In each of the heavens and in each of the hells, as well as in the world of spirits, there are innumerable societies, each society consisting of those who are governed by the same ruling love, and are drawn and held together by a similarity of interior life and character. The heavens are founded on the two great commandments of love to God and the neighbor. All the angels, being under the constant influence of these loves, constitute a kingdom of uses; each society and each individual having a peculiar function or office to perform for the use and benefit of the rest; and all working together in the most perfect freedom, and with affection and delight, in harmonious connection, like the different organs or members of the same human body. They thus make one Greatest Man, within which dwells the Lord himself, giving life and intelligence to, and ruling in the heart of each and of the whole. The hells are the opposites of the heavens; the evil spirits of which they consist being under the influence of the loves of self and of the world, which are directly opposed to the love of God and the love of the neighbor. These loves are essentially discordant and distracting in their nature, and tend to bring those in whom they exist into conflict with each other, and to produce results directly opposite to those exhibited in the heavens. Into "the world of spirits" all persons first enter immediately after death. It consists of those who have passed out of the

natural world into the spiritual, and who are not yet fully prepared either for heaven or hell. In this world of spirits men are as to their spirits, even while yet alive on earth. Above them are the heavens; beneath are the hells; and about them on all sides is the world of spirits. By these influences above, beneath, and about them, men are held in equilibrium, and thus in freedom to turn either in one direction or the other. If this freedom should be lost or destroyed, reformation and regeneration would be impossible. At the time of the advent of the Lord, such was the accumulation of the evil in the world of spirits, that this equilibrium was in danger of being destroyed, and human freedom lost. The hells had, as it were, risen up out of their proper places; devils were taking possession of the souls and bodies of men; and the human race was threatened with impending destruction. The work of redemption consisted in rolling back this tide of evil; in casting out the devils and subjugating the hells; and thus restoring and preserving human freedom, which would otherwise have been lost. By this means it was made possible for all to keep the commandments of God, and to attain to heavenly life and happiness.—It is important here to understand the nature of the divine power or omnipotence. The power of God is the effect of the operation of the divine will and understanding, or of the divine love and wisdom, and must of course be limited by them; or, in other words, it is not possible for God to do any thing which is opposed to his own nature, or any thing which is not good and wise. His love extends to all created beings, even to those who are in the hells; as "he maketh his sun to rise on the evil and on the good." The effect of his government over evil spirits is to keep them within bounds, and to make them less hurtful to each other, and less miserable than they would be otherwise. To restore order, therefore, to the spiritual world, he must adopt the method which his own divine love would prompt, and his own divine wisdom provide. The wheat must be separated from the tares without the loss of the least portion of it; and this must be effected without doing violence to the freedom of any. For this purpose, Jehovah clothed himself with that part of human nature which is derived from the mother, consisting not only of a material body but also of the external parts of the mind. The everlasting Father could not be tempted; but the assumed humanity, deriving from Mary tendencies to evil, could meet evil spirits on their own plane; was subject to temptations; and as these temptations were resisted, the divine influence and power were brought down into that region where their presence was needed, in order to remove the disorders which had arisen in the spiritual world, and to restore and preserve the freedom of the human mind. Had the essential Divinity descended without being thus veiled and clothed, it would have been

like a consuming fire, both to the evil and to the good who were still connected with the evil. All evils have a connection and relationship with each other, as well as all evil spirits; and in the evils of the assumed humanity the indwelling Divinity could meet, resist, and subjugate all the hells. At the same time, and by the same means, the humanity was glorified, or made one with the Father. All that was derived from Mary was gradually put away, so that he no longer acknowledged her as his mother; and its place was supplied by the divine life, affections, and thoughts which flowed down from within. At first there was opposition between the indwelling Divinity and the external humanity. The will of the latter was not in harmony with the will of the former, but opposed to it. The assumed humanity was the seat of the most grievous trials and temptations. To this the words apply: "I seek not mine own will, but the will of the Father which hath sent me." It was necessary that it should give up its own peculiar life; and as soon and as fast as this was done, it was brought into harmony and union with the Father within. In this way the humanity was glorified, or made divine, and thus became a perfect medium of the essential Divinity. This work was going on during the whole period of the sojourn of the Lord on the earth. The last and most grievous temptation was that on the cross. The work was then finished, or nearly so; for the union of the Divinity with the humanity was not perfect till the final ascension. That which to the external observer appeared to be death, was really the lifting up of the humanity, and the uniting of it more fully with the Father, that it might draw all men unto itself. Even the material body was gradually changed into a divine natural body. Nothing of it remained in the sepulchre; and after the resurrection it was no longer subject to the laws of matter, but was present with the disciples, the doors being shut. As the humanity was made divine, all power was given to it in heaven and on earth; for it is in and through the glorified humanity alone that the divine love and wisdom operate.—By assuming humanity, and glorifying it, Jehovah not only subjugated the hells, and thus performed the work of redemption, but restored order to the heavens; for the angels are not good and wise of themselves, but are only recipients of love and wisdom from him. They are not perfectly pure and beyond the reach of evil influences, but are better than men because they are more humble, and more willing to acknowledge the source of their goodness. In removing the evils from his humanity, the Lord at the same time made the heavens more receptive of his spirit. The influence of the work of redemption, therefore, extended not only to men, but to angels; and by bringing down his divine life into the lowest plane, even to the ultimates of the natural world, and putting on the divine natural or Divine Humanity, Jehovah clothed himself with

power to hold the hells in subjection for ever. By the accomplishment of this work he was able to reach and affect the minds of men with a new influence and power; agreeably to the words: "The Holy Spirit was not yet, because that Jesus was not yet glorified;" and after the resurrection "he breathed on his disciples, and saith unto them, Receive ye the Holy Spirit." He also made himself visible, and thus became a distinct object of thought and affection; that by loving him and being conjoined to him, men might have eternal life and happiness. The infinite Father, in himself invisible and inaccessible, thus became "Immanuel, God with us." The Holy Spirit is an emanation of love and wisdom from the Divine Humanity, like heat and light from the sun. The essential Divinity, the Divine Humanity, and the Divine Proceeding—Father, Son, and Holy Spirit—like soul, body, and operation in man, constitute the one triune God.—Such is a brief statement of the New Church doctrine of redemption. The accomplishment of this work has rendered it possible for all men to be saved; but their salvation cannot be effected without coöperation on their part. There is in the spirit of every person an internal man and an external man, or a spiritual mind and a natural mind. At birth, the infant has no distinct thoughts or affections. He first acquires the use of his senses, which is in itself a great work. The external, sensuous parts of the mind are next opened; and he gradually attains the power of willing and thinking. It is a long time before the higher faculties are developed. These are at first concealed from his view; and in this we have an image of the state of the Lord during infancy, when the Father was deep within, and (perhaps) not at first distinctly recognized by the assumed humanity. During this period of infancy and childhood man is kept in a state of dependence upon others, especially his parents, and is guarded by angels whose province it is to cherish and preserve all innocent and kindly feelings and thoughts. This period of long dependence upon others, which distinguishes man from all the animal creation, is of divine providence, that he may be thereby prepared to feel and acknowledge his entire dependence on his heavenly Father; which is an indispensable condition of eternal life and happiness. The hereditary evil tendencies of his nature are at first in a great measure quiescent, but are permitted gradually to appear, as he is able, if he is faithful to his duty, to resist them and put them away. The natural mind is developed by things pertaining to this world, including the arts and sciences, languages, history, &c. If the development goes no further than the natural mind, the rational faculty must be narrow in its views, liable to be warped by evil desires, and, wanting that interior illumination which can come only from above and within, comparatively blind, and constantly exposed to false conclusions and inferences. The spiritual mind is

opened only with those who shun evils as sins against God; with others it remains closed. As this mind is opened by shunning evils as sins, there is given an affection of spiritual truth, and with the affection an internal perception of what is true. The truth is then received rationally and in freedom. The evidence of miracles is not only not required, but would be injurious; because the external mind would thereby be compelled to admit that for which the internal affections were not prepared; whereas the truth can be fruitful in good works, and subserve its highest use, only when it is implanted, in freedom, in the heart and life. As the spiritual mind is opened, it is capable of discerning spiritual truths, as the natural mind discerns natural truths. The work of regeneration consists in bringing the external, natural man into subjection to and correspondence with the internal, spiritual man. It is an image of the glorification of the humanity of the Lord. He stands at the door of the mind of every one and knocks; but he cannot enter unless the person first opens the door, by removing the evils of the external man, which is done only by shunning them as sins against God. If they are shunned for any other reason, they are not removed. A person may abstain from committing evils on other grounds, as for instance from a regard to his own reputation; but in this case the disposition to commit them will remain. The evil must be shunned not only in the act, but in the thought and affection; for therein is its seat and origin. But it must be remembered that "none is good save one, God;" that he alone is able of himself to resist evil; that all the power of angels and men is derived from him; and that evils should be shunned as of ourselves, but with the constant acknowledgment that the ability to shun them is derived from him alone. If this is done, and they are put away internally as well as externally, then, as the evil affections are removed from the mind, the Lord will be present, and communicate the opposite good affections in their place. He glorified his humanity in order that he might perform a similar work in man; and in proportion as any one follows him in the regeneration, he will be the better able to understand the process of the Lord's glorification, for he will have an image of it in himself.—The internal or spiritual, and the external or natural mind have been mentioned; but, strictly speaking, there are three degrees in the human mind, the one within or above the other. These are called the heavenly, the spiritual, and the natural, corresponding to the three heavens above described. With all other animals, the two higher degrees are wanting; they are therefore incapable of having human affections and thoughts; they have not in their nature the possibility of thinking of and loving the Lord, and thus being conjoined to him; and therefore they do not live to eternity. Degrees, as understood in the New Church, are of two kinds, and are called continuous and

discrete. Continuous degrees are degrees of more or less in the same thing, like the degrees of density in the atmosphere, or of light and heat from morning to evening. Discrete degrees exist between things internal and things external; which so differ in their nature, that the one cannot by any possibility become the other. Thus the soul and the body differ by discrete degrees. Matter may be more or less refined, but by no possible sublimation can it be made spirit. Between the internal and the external, in things separated from each other by discrete degrees, there is the relation of correspondence; and communication between them exists by the influx of the former into the latter. The relation is similar to that of cause and effect. Thus the body corresponds to the spirit; and the spirit communicates with and actuates the body, to which it corresponds, by influx. So also with the parts of the body. The eye corresponds to the understanding; and the action of the understanding into the eye, which causes vision, is influx. The heart corresponds to the will; and the involuntary action of the will into the heart, which causes its pulsations, is influx. The three heavens, as also the three planes or provinces of the human mind, are separated from each other by discrete degrees; and the relation and connection between them is by the influx of the higher into the lower, which takes place because between them there is correspondence. The natural world is separated from the spiritual by discrete degrees. All things of the former have their prototypes in the latter, to which they correspond; and the relation and connection between them is by influx. All animal and vegetable life depends upon this influx from the spiritual world. At the same time, the natural world with its inhabitants is necessary for the spiritual world and its inhabitants, and serves as a foundation on which they rest. Thus there is the most intimate relation and mutual dependence between them.—The same law of correspondence explains the Sacred Scripture. It is a divine work, and is written in a manner analogous to that in which the world is created—according to the correspondence of natural things with spiritual. It has a spiritual sense throughout within the literal, as the spiritual world exists within and animates the natural world, and as the soul exists within and animates the body. This spiritual sense does not relate to things pertaining to the natural world, but wholly to those which are spiritual; thus, to regeneration, to redemption, and the glorification of the humanity of the Lord. The recorded events of the history of the Israelites were providentially ordered for this purpose; and whatever may be the case with the letter, the spiritual sense flows on in a harmonious and consistent series, being represented by the coat which "was without seam, woven from the top throughout;" while the literal sense, like the outer garment of our Lord, may be torn into pieces, and distributed among men.

as they choose one or the other fragment. There is also in the Word a sense still more interior than the spiritual; it is called the heavenly. It cannot be easily unfolded, not being so much the subject of thought as of affection. These three senses answer to the three degrees in the human mind. The Sacred Scripture exists in the heavens, and is the inexhaustible source of wisdom to the angels. In its first origin it is altogether divine; and as it descends through the heavens, it is understood by the heavenly angels in the heavenly sense, and by those who are spiritual in the spiritual sense. The literal sense contains the other senses, and is the foundation on which they rest; as the natural degree of the mind contains the spiritual and celestial, or as the body contains the soul. The Word is thus divinely inspired and holy throughout. Its inspiration is a present reality. The devout reader is brought into immediate and direct connection with the angels, although unconscious of their presence; and these angels are in the perception of the interior senses, which communicate with the literal by influx and correspondence; and within the whole is the divine influence imparting love and light both to angels and men. The Sacred Scripture differs from all other books, as what is divine and infinite differs from what is human and finite, and as the Lord differs from all men. It is called a testament or covenant, because it brings those who truly keep the commandments, by shunning the evils therein forbidden as sins against God, into communion and interior union with him. It is thus the divinely appointed means by which men are conjoined to the Lord, and consociated with the angels. Without this provision, the human race would perish.—All knowledge of God, of spiritual things, and of a future state of existence, is derived, either directly or indirectly, from revelation. The various forms of idolatry, wherever they are found, are the perversions of what was once true and pure religion. The external objects, which were originally prized because they brought to mind the internal things to which they corresponded, became, when all affection for and knowledge of what is spiritual was lost, objects of worship. Thus the sun, which represents the Lord, and which at first only reminded men of his glory and his goodness, was at length itself worshipped by those who ceased to raise their thoughts above their senses. There was a written revelation previous to that given to the Israelites. The "Book of the Wars of Jehovah" spoken of in Numbers, and the "Book of Jasher" referred to in Joshua and Samuel, were parts of this Word. From this also Moses copied the first chapters of Genesis, including the account of the creation, of the flood, &c.; which, though written in the historical style, are not true in the literal sense. Adam, Seth, Enoch, Noah, Ham, Shem, Japheth, &c., did not exist as individuals, but signify respectively churches, or states of

mankind or of religious belief. True history begins with the generations of Terah, the father of Abraham, in the 11th chapter of Genesis. Some of the books generally supposed to constitute a part of the Sacred Scriptures have not the internal sense in a connected series, and are not inspired according to the meaning of inspiration in the New Church. The estimation in which these books are held by this church does not vary materially from that with which they are regarded by others; but the value and importance which it attaches to those which are inspired is so far beyond any thing that the world has hitherto imagined, that these are regarded as comparatively of much less importance. The books which constitute the inspired Word, in the sense just mentioned, are the following: in the Old Testament, Genesis, Exodus, Leviticus, Numbers, Deuteronomy, Joshua, Judges, 1st and 2d Samuel, 1st and 2d Kings, the Psalms, Isaiah, Jeremiah, Lamentations, Ezekiel, Daniel, Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, Malachi; and in the New Testament, the four Gospels and the Book of Revelation.—The divine providence is the government of the divine love and the divine wisdom of the Lord, and is in all things, even the most minute and particular. It always looks beyond things temporal and finite, and regards the salvation and eternal welfare of man. Its great end is a heaven from the human race. For this purpose man was created by God into his own image and likeness, capable of receiving his love and wisdom freely and rationally, with an acknowledgment of him from whom they proceed. No finite created being can be more than this, though the human and angelic mind is capable of being enlarged and perfected to eternity. All angels are men in an advanced stage of their existence. There is not an angel in the heavens, nor an evil spirit in the hells, who did not commence his existence in this or in some other natural world; and there is no human being who is not already, or will not become, either an angel in heaven or an evil spirit in hell. The natural world is designed to be the seminary of heaven. After death, the real man continues to live on as before. He has lost nothing but the material body, which derived all the vitality it at any time possessed from the spirit. Death, or the withdrawal of the spiritual from the material part, is not an instantaneous or very sudden process. It is usually fully accomplished on the third day after respiration ceases. The man then lives only in the spiritual world, and is in all respects the same as he was before death; except that he is clothed with a spiritual body instead of a material one, which is adapted to the world in which he now lives, as the material one was to this. He has the same affections and thoughts and capacities as before. Nothing of his life in the world is lost or forgotten, but all is laid up in his interior memory. He sees, hears, and handles things in that world, as he

formerly did the things of this world. He is surrounded by objects similar in appearance to those which he has left behind him; and they are altogether real and substantial, though not material. But he has passed into a world of substantial realities, in which the laws of time and space differ greatly from those in this world. Spiritual distance is caused by dissimilarity in the life and affections; and the successive changes in them produce the appearance of longer or shorter duration. Time and space are no longer masters, but servants; being appearances produced by the internal state of the angels and spirits, and subject only to spiritual laws. All things in that world exist in relation to the spiritual sun, as all things in this exist in relation to the natural sun. As it is with time and space, so it is with all the external objects by which the angels and spirits are surrounded. These correspond to their interior life and affections, and depend upon them. The imagination of man cannot conceive of the beauties of paradise; but the kingdom of heaven exists around the angels, because it exists within them. It is not a place into which any one may be permitted to enter in an arbitrary manner. He cannot be in heaven externally without being there internally, or without having heaven in himself. When any person dies, and is raised up in the spiritual world, he is received by the angels with the most tender love. They perceive his real state and character, and are ready to instruct him in heavenly things so far as he is willing to be so instructed, and are glad to do him all the good in their power. It is well known that a very large proportion of the human race die during the period of infancy and childhood. All these are saved; for they have not confirmed themselves in evil, and are capable of being so instructed and educated by the angels, that they may be prepared for heavenly life and happiness. As they are so led, and their hereditary evils are subdued and removed, they grow to maturity in stature, as in goodness and wisdom, and at length become angels. There are places of instruction for this purpose in the "world of spirits." Those who die at mature age are judged according to their works. The intentions and the acts of a person are inscribed on his interior memory. This is the book of his life. After death all power of dissimulation is taken away; and this book is opened, and he is judged according to the things therein written. If he is internally good, having acted from a love of the Lord and the neighbor, whatever exists in the external parts of his mind which does not agree with his real character is put away, and he is prepared for heaven. If he is internally evil, having confirmed himself in the love of self and the world as his ruling principle of action, all his seeming goodness is removed by the current of his own affections; and of his own choice he seeks the company of those who are in a state similar to his own, and finds them in the hells. As the

tree falls, so it lies. The inmost state of his life, or his ruling principles, can never be changed, however their manifestation may be controlled or suppressed through punishment or the fear of it, or by other similar means.—It was said that the earth was designed to be the seminary of heaven. For the accomplishment of this end, it is not only necessary that men should be born, but that they should be so constituted and so circumstanced, that the great purpose of their existence may be attained. For this end the marriage of one man with one woman is of divine order and appointment. It has its origin in the two constituents of the divine nature, love and wisdom; and the male and female minds are so formed as to be the counterparts of each other, and, when united by true conjugal love, to constitute one mind. They can be so united only when the spiritual mind is opened. They are then conjoined to the Lord by the reception and acknowledgment of his influence, and by a life according to his commandments; for he is the Bridegroom, and the church is the Bride; and true conjugal love descends from this heavenly marriage. The distinction between the sexes, having its origin in the mind, must continue to eternity. The husband partakes more of the intellectual character, and the wife more of the affectional; and by true marriage the love of himself and of his own intelligence is taken out of the man, where it is evil, and shows itself in pride or vanity, and is transferred to the wife, where it is good and useful. The married partners, not being divided in their affections, and never forgetting or losing their love for each other, will feel and think chastely and purely, and mutually aid each other in the work of regeneration and the uses of life. Their love of their children will partake of the quality of their love of each other, and will continually regard and seek their spiritual good and happiness. Such love is now extremely rare; but it once prevailed on the earth, and it is the constant effort of Divine Providence to restore it. As it is restored, the hereditary evils which have been transmitted from generation to generation will be gradually softened and extirpated. The angels live thus united, husband and wife, in perpetual youth, innocence, and peace; finding their delight and happiness in the performance of useful works, each fulfilling the functions for which he is specially adapted. As has been said, it is the order of Providence that they should commence their existence in some material world, and marriages in the heavens are without procreation, or the production of children. But, being founded on the union of love and wisdom, or goodness and truth, a continual increase of love and wisdom flows from this union as its legitimate offspring. In the language of Swedenborg (*"Apocalypse Explained,"* No. 993): "That love truly conjugal contains in itself so many ineffable delights that they exceed number and expression, may also be evident from this, that that love

is the fundamental love of all heavenly and spiritual loves, since by it man becomes love; for from it spouse loves spouse, as good loves truth and truth loves good; thus, representatively, as the Lord loves heaven and the church; such love cannot exist but by marriage, in which the man is truth and the wife good. When man has become such love by marriage, then also he is in love to the Lord, and in love toward the neighbor; consequently in the love of all good, and in the love of all truth. For, from man as love, nothing but loves of every kind can proceed; hence it is that conjugal love is the fundamental love of all the loves of heaven. Now because it is the fundamental love of all the loves of heaven, it is also the foundation of all the delights and joys of heaven; for all delight and joy is of love. It follows that heavenly joys, in their order and in their degrees, derive their origins and causes from conjugal love. From the felicities of marriage it may be concluded as to the infelicities of adulteries; namely, that the love of adultery is the fundamental love of all infernal loves, which in themselves are not loves but hatreds; consequently that it is the love of adultery from which flow forth hatreds of every kind, as well against God as against the neighbor; in general, against all the good and truth of heaven and of the church. Hence to it belong all infelicities; for from adulteries man becomes a form of hell, and from the love of them he becomes an image of the devil."—Another essential means by which the great end of creation, a heaven from the human race, is effected, is the church. The church is designed to be the gate of heaven. It is the foundation on which the heavens rest; and it is necessary that there should always be an unbroken connection between them. Without this the human race would perish. It has been said that conjunction with the Lord and consociation with the angels is effected by means of the Sacred Scriptures. But for this end it is necessary that there should be a church by which the Lord is acknowledged, and the Sacred Scriptures received and understood. Hence there has always been a church on the earth. "The angelic heaven cannot be separated from mankind, nor mankind from the angelic heaven; wherefore it is provided by the Lord that both the angelic heaven and mankind mutually assist and support each other." The church is to the rest of the human race what the heart and lungs are to the body. There have been four churches, or dispensations, on the earth, which were entirely distinct in their character from each other. As one has gradually declined till it finally became extinct in consequence of the loss of charity and faith, another, distinct in its character, has been raised up to take its place. At the end of every church there has been a general judgment in the spiritual world, of those who have lived during that dispensation; and a new heaven has been formed preparatory to the formation of a new

church. At that time vast multitudes have been collected together in the world of spirits, consisting of those who have died during the existence of the church which has come to an end, and who are of such a character that the good could not be separated in freedom from the evil till the final consummation. It should be understood, however, that all who had died in infancy and childhood during this period were already in the heavens, as well as many others whose lives on earth had prepared them for the society of angels. The consummation of the first or most ancient church is symbolically described in Genesis by the flood; at which time a judgment was accomplished, and the next succeeding church established, which is called the ancient church. Under the Israelitish dispensation, which was the closing period of the ancient church, conjunction with the heavens was not effected by the reception of what is good and true into the heart and life, but by means of outward observances which represented things internal and spiritual. When the Lord was on the earth, a second general judgment was accomplished in the spiritual world, and the first Christian church established. This church continued till the year 1757, during which year the last general judgment was accomplished also in the spiritual world on those who had lived during that dispensation, and the New Jerusalem church was formed. The two essentials of this church are the acknowledgment that the Lord Jesus Christ is the only God of heaven and earth, and that there is conjunction with him by a life according to the precepts of the decalogue. The New Jerusalem, being the last and crowning dispensation, founded on the revelation of the spiritual sense of the Sacred Scriptures, which is an infinite and exhaustless source of divine truth, will not come to an end. It will continue to increase in the knowledge and love of the Lord for ages of ages. There will consequently be no other general judgment. All who die are judged soon after passing into the spiritual world; and none now remain in the "world of spirits" for a longer period than 80 years. The wonderful changes, revolutions, and improvements that have taken place during the last century, and make this period the most remarkable in the world's history, are the fruits of the last judgment; by means of which the minds of men were liberated from spiritual bondage, and opened to new, stronger, and higher influences. The revelation of the spiritual sense of the Sacred Scriptures is signified by the coming of the Lord "in the clouds of heaven, with power and great glory." By clouds is there denoted the literal sense of the Word. The spiritual sense of the Apocalypse or Book of Revelation relates particularly to the consummation of the Christian church, to the last judgment, and to the establishment of the new heavens and the new church, which is called the New Jerusalem. This is distinct from the first Christian church, as the first Christian was

distinct from that which preceded it. In the language of Swedenborg: "This second coming of the Lord is effected by means of a man, before whom he has manifested himself in person, and whom he has filled with his spirit, to teach the doctrines of the New Church through the Word from him. That the Lord has manifested himself before me, his servant, and sent me on this office, and that, after this, he opened the sight of my spirit, and thus let me into the spiritual world, and gave me to see the heavens and the hells, and also to speak with angels and spirits, and this now continually for many years, I testify in truth; and also, that from the first day of that call, I have not received any thing which pertains to the doctrines of that church from any angel, but from the Lord alone while I read the Word."—In the early period of the human race, represented by the term Adam, men were permitted to enjoy open communication with the spiritual world, and to converse with the angels of heaven. But after the mind of man became perverted and corrupted, if this intercourse had been allowed to continue, it would have been attended with great spiritual danger and harm, threatening even the extinction of the race. It was therefore of divine providence that this communication should cease, and a thick veil be drawn between the spiritual world and the natural; so that a knowledge of even the existence of the former, and of its realities, should be altogether obscured, and in a very great measure lost. The spiritual senses of the prophets, however, were opened; for which reason they were called seers. This was to the intent that they might be able to write the books of the Sacred Scriptures, which consist in good part of things heard and seen in the spiritual world, which they were commanded to record. The spiritual senses of Swedenborg were opened, that he might thereby be enabled to understand and disclose the laws by which the Scriptures were written, and reveal their spiritual sense, and thus be the means through whom the second coming of the Lord was effected. But all attempts to have open communication with departed spirits, by magic, witchcraft, or necromancy, are repeatedly and emphatically prohibited in the Old Testament. These prohibitions still remain; and the phenomena of spiritism, so far as they are real, come under these prohibitions, and are disorderly and dangerous. Visions have doubtless been occasionally granted in the different ages of the world; but, when orderly and useful, they have not been sought for, but have been freely given by the providence of the Lord. Swedenborg was, of all men, in a position to see clearly the dangers attending open communication with the spiritual world, and frequently warns his readers against these dangers. Every man is attended by two angels from heaven, and two evil spirits from hell. The angels perceive the quality of his affections and thoughts, and are constantly endeavoring to

avert evil influences, and impart those which are good. But they have no perception of man by sight, or touch, or hearing. The evil spirits do not know that they are with man; but they are attracted to him by that which is evil in the sphere of his life, into which they enter, not knowing that it is not their own. If he shuns evils as sins against God, they can do him no harm; but their influence will be useful to him, in enabling him to see and remove the evil tendencies of his nature. By means of these attendant angels and spirits, he is connected with the heavens above and the hells beneath, and is held in freedom to turn either to the one or to the other.—Baptism and the Lord's supper are holy sacraments of the church, representing and signifying things spiritual and divine, and designed as the means of communicating to man those blessings of which they are the outward symbols. Baptism represents regeneration, which is effected by cleansing the spirit from evils by the application to the mind of those truths which are signified by water, which are the truths of the literal sense of the Word. It is a sign which is perceived by the angels, and is the divinely appointed means by which the person baptized is brought under those spiritual influences best suited to his state, and best adapted to promote that which is signified by that sacrament, namely, his regeneration. It should precede the Lord's supper. The latter sacrament is the most holy act of worship. The bread, which is called the flesh of the Lord, corresponds to his divine love or goodness; and the wine, which is called his blood, to his divine wisdom, or to the interior truths of his Word. Those who receive them worthily, receive also those things which they represent, and are by the act brought into consociation with the angels of heaven, and into conjunction with the Lord himself.—The above is an imperfect sketch of the doctrines of the New Jerusalem church, as it is believed that the writings of Swedenborg teach, and the members of the church hold them. These doctrines are fully set forth in his theological writings, an enumeration of which will be found in the article under his name. It will be seen that they are not of a character to obtain a rapid reception. During the life of Swedenborg the number of those who received them was extremely small, at which he does not seem to have been in the least degree surprised or discouraged; and for their slow reception he gives distinct and sufficient reasons. A century has elapsed since the commencement of the New Church, and the number of those who openly profess to be receivers of its doctrines, and members of the church, is still comparatively small. It is greatest in the United States and in England. These doctrines find, however, zealous advocates in France, Germany, Sweden, Switzerland, and indeed in almost every portion of the Christian world. In England there is a general conference of the New Church,

which holds an annual session in different parts of the kingdom. In the United States there is also a general convention of the New Church, which meets annually in different places. There are church societies in both countries not in connection with these organizations. The general conference has published a liturgy which is very generally used in England. A liturgy has also been published, and from time to time revised, by the general convention of the New Church in the United States. Several periodicals, both in England and America, are devoted to the elucidation and dissemination of its doctrines, and various able writers have published works for the same purpose. In the public worship of the New Church in this country, generally speaking, no prayer but the Lord's prayer is used. The music consists mostly, and in many places entirely, of chants and anthems, the words of which are taken wholly from the Sacred Scripture. The liturgy of the general convention, beside the liturgical portion of the book, contains 240 pages of scriptural selections, with suitable chants and anthems. The words of Scripture are regarded by the New Church as possessing an influence and a power in worship, whether in prayer or singing, altogether above those of any merely human composition.

NEW KENT, a S. E. co. of Va., bounded N. E. by the Pamunkey river, and S. W. by the Ohiohominy; area, about 200 sq. m.; pop. in 1850, 6,064, of whom 3,410 were slaves. Its surface is moderately uneven, and the soil light and sandy. The productions in 1850 were 178,813 bushels of Indian corn, 37,846 of oats, 13,650 of sweet potatoes, 5,233 lbs. of wool, and 38,031 of butter. There were 12 grist mills, 10 churches, and 800 pupils attending public schools. The value of real estate in 1856 was \$917,121, being an increase since 1850 of 29 per cent. Capital, New Kent Court House.

NEW LANARK. See LANARK.

NEW LEBANON, a N. E. township of Columbia co., N. Y.; pop. in 1855, 2,329. In the E. part is a large Shaker settlement of from 500 to 600 persons (including a few in the adjoining town of Canaan), owning about 4,000 acres of land. They have a large meeting house, a laboratory, a grist mill, 5 saw mills, 2 machine shops, 8 dwellings, and a stone barn 196 by 50 feet, said to be the most perfect barn in the country. Ventilation is thorough, and the manure is deposited in a vault at the end of the barn, for which purpose railroads pass the whole length of the building on either side. Their principal occupation is the raising and putting up of medicinal plants and garden seeds, the preparation of roots and extracts, and the manufacture of brooms and baskets. Of garden seeds and medicinal articles the annual production is about 200,000 lbs. The township contains 8 places of worship, viz.: 1 Baptist, 1 Christian, 8 Methodist, 1 Presbyterian, 1 Roman Catholic, and 1 Shaker.—NEW LEBANON

SPRINGS, a village in the above township, 25 m. S. E. from Albany (pop. in 1855, 278), is noted for its thermal springs. There are several springs, the largest of which is 10 feet in diameter and 4 feet deep, and discharges 16 barrels of water per minute. According to an analysis made by Dr. Meade, 1 pint of water contains 0.25 gr. chloride of calcium, 0.44 gr. chloride of sodium, 0.19 gr. carbonate of lime, and 0.37 gr. sulphate of lime. Gas, composed of 89.4 parts nitrogen and 10.6 parts oxygen, is constantly given out in the proportion of 5 cubic inches for every pint of water. The discharge of this spring supplies several baths, and keeps 2 or 8 mills running throughout the year. The waters have a uniform temperature of 73° at all seasons. The village contains 2 churches, 4 hotels, and a female seminary.

NEW LEON, or NUEVO LEON, a central state of Mexico, bounded W. and N. by Coahuila, E. by Tamaulipas, and S. W. by San Luis Potosi and Zacatecas; area, 16,687 sq. m.; pop. 146,281. Portions of it are very mountainous, a spur of the great Sierra Madre terminating near the city of Monterey. Between the mountains are broad barren plains, but along the streams are rich alluvial valleys, which with artificial irrigation yield abundant crops. The chief rivers are the Sabinas, Salado, San Juan, and San Fernando or Tigre. The climate, although hot at all seasons of the year, is considered healthy. The chief productions are live stock, consisting of horses, mules, horned cattle, sheep, and goats, for the raising of which the plains and valleys are well adapted. Very large numbers of mules are raised, which find a ready market in other parts of Mexico and in Texas. The annual product of the soil has been stated by Mexican authorities to average 360,000 bushels of Indian corn, 15,000 bushels of beans (*Frijoles*), and 46,500 cwt. of sugar. The last is put up in small cakes, and is worth about 3 cents a pound by the quantity; it is of a dark color, and inferior to the West India sugars. Salt is also made on the banks of the Tigre. The state was formerly rich in silver mines, but from the want of capital and enterprise, and of protection from the Indians, who commit great ravages here, the mines are either imperfectly worked or have been abandoned. The principal city is Monterey, the capital.

NEW LISBON, the capital of Columbiana co., Ohio, on the Little Beaver river and on the Ohio and Danby canal, 155 m. N. E. from Columbus and 56 m. from Pittsburg; pop. in 1859 estimated at 3,000. It is neatly and compactly built, and, being situated in the midst of a fertile, populous, and highly improved region, noted as one of the chief wool growing districts of the state, is rapidly increasing in importance. The Little Beaver river supplies it with abundant water power. It contains 8 printing offices, 2 machine shops, 1 saw mill, 3 grist mills, about 25 stores, and 7 churches (Disciples', Dutch Reformed, Episcopal, Friends', Methodist, Presbyterian, and Seceder).

NEW LONDON, a S. E. co. of Conn., on Long Island sound, bordering on Rhode Island, bounded E. partly by the Pawcatuck and W. by the Connecticut river, and drained by the Thames river; area, about 650 sq. m.; pop. in 1850, 51,821. The surface is hilly, and in the S. W. mountainous; the soil is best adapted to grazing. Fishing is extensively carried on. The productions in 1850 were 243,412 bushels of Indian corn, 38,904 of rye, 99,823 of oats, and 80,110 lbs. of wool. There were 22 grist mills, 60 saw mills, 22 woollen and 17 cotton factories, 5 founderies, 5 printing offices, 7 newspapers, 102 churches, and 10,078 pupils attending public schools. The county is traversed by the New London, Willimantic, and Palmer railroad, and partly by the Norwich and Worcester and New Haven and New London railroads. Shire towns, New London and Norwich.

NEW LONDON, a city and port of entry and semi-capital of the preceding county, situated on the right bank of the Thames river, 3 m. from its entrance into Long Island sound, and 50 m. E. from New Haven; lat. $41^{\circ} 18' 57''$ N., long. $72^{\circ} 5' 4''$ W.; pop. in 1850, 9,006; in 1860, 10,116. It is built on a declivity sloping toward the S. and E., and the ground in the rear of the city rises to a considerable height. The streets were not originally laid out with much regularity, but have been greatly improved of late years, and the new quarters are well graded. The private residences, owing partly to the influx of summer visitors who are attracted by the beautiful scenery of the neighborhood, are in many cases elegant and picturesque. A fine hotel which has for some years been sustained near the entrance of the harbor (the Pequot house) has also made this city a fashionable summer resort. Among the public buildings are a handsome granite custom house, a substantial and elegant brown stone city building in which also the post office is situated, the court house, and other county offices, and 10 churches, viz.: 3 Baptist, 2 Congregational, 1 Episcopal, 2 Methodist, 1 Roman Catholic, and 1 Universalist. There is an excellent school system, and beside 17 public schools the city has a female academy, and the Bartlett high school. It has a public library with 3,000 volumes, 2 daily and 4 weekly newspapers, 4 banks with an aggregate capital of \$600,000, 2 savings banks, 3 iron founderies, 2 steam saw mills, a flouring mill, and a horse-shoe nail factory. The Albertson and Douglass machine company (capital \$60,000), the Wilson manufacturing company (capital \$100,000), and the Naumkeag manufacturing company (\$70,000), are among the largest industrial establishments. A small amount of capital is invested in ship building, 4 vessels with an aggregate burden of 290 tons having been launched during the year ending June 30, 1860. The harbor is the best on Long Island sound, and one of the best indeed in the United States. It is 8 miles long and 5

fathoms deep, sheltered by hills seldom obstructed by ice, and defended by Fort Trumbull at the entrance. This fortress, which has been almost entirely rebuilt since 1840, is one of the best in the country, and mounts 80 pieces of heavy ordnance. It has accommodations for a garrison of 800 men. At the town of Groton, on the opposite side of the river, are the ruins of Fort Griswold, the scene of a massacre by the British in 1781. (See GROUT.) The inhabitants of New London have long been actively engaged in the whale fishery, in which the city ranks second only to New Bedford. The coasting trade and other fisheries are also very important. On June 30, 1860, the shipping of the district amounted to 37,490 tons, of which 17,924 was registered and 19,566 enrolled and licensed. Of this the whale fishery employed 13,066 tons, the cod fishery 4,957, and the coasting trade 15,116. During the year 1858-'9 the entrances were 28 American vessels, tonnage 7,558, and 11 foreign, tonnage 1,545—total, 39 vessels, 9,103 tons; and the clearances were 20 American, tonnage 5,492, and 9 foreign, tonnage 1,275—total, 29 vessels, 6,767 tons. The imports amounted to \$484,718, and the exports to \$173,908. There are two lines of daily steamboats to New York, and the New London, Willimantic, and Palmer, and the New York and Boston (shore line) railroads offer easy communication with all parts of the country.—New London was settled in 1644 by John Winthrop, son of the governor of Massachusetts. On Sept. 6, 1781, it was captured by a British force under Benedict Arnold, who set fire to the stores and shipping, and reduced the most valuable part of the town to ashes. They then attacked Fort Griswold at Groton, and massacred the garrison after it had surrendered. Fort Trumbull, not being tenable, as it was much exposed on the land side, had been evacuated.

NEW MADRID, a S. E. co. of Mo., bordering on the Mississippi river, by which it is separated from Kentucky and Tennessee; area, 880 sq. m.; pop. in 1856, 4,317, of whom 1,649 were slaves. The surface is low and level, and in some places very productive. The remarkable earthquakes of 1811-'12 (see EARTHQUAKES, vol. vi. p. 722) severely injured this region, leaving a large portion of the land, now known as the "sunk country," under water. Various efforts have been made to reclaim the land. The productions in 1850 were 586,260 bushels of Indian corn, 13,260 of oats, and 2,419 lbs. of wool. There were 4 grist mills, 2 saw mills, 1 tannery, 1 printing office, 1 newspaper office, 8 churches, and 332 pupils attending public schools. Capital, New Madrid.

NEW MEXICO, a territory of the United States of America, and formerly one of the Mexican states, bounded N. by Utah and Kansas, E. by Kansas, Indian territory, and Texas, S. by Texas and Mexico, and W. by California. It lies between lat. $31^{\circ} 10'$ and 38° N., and long. 103° and $117^{\circ} 9'$ W. Its greatest length is about 700

m., its breadth from 850 to 400 m., and its area nearly 220,000 sq. m. It is divided into 8 counties, viz.: Bernalillo, Donna Anna, Rio Arriba, San Miguel, Santa Anna, Santa Fé, Socorro, Taos, and Valencia. The principal towns are Santa Fé, the capital, Albuquerque, Socorro, and Taos. All that part of the territory lying S. of the river Gila and W. of the Rio Grande, comprising Donna Anna county, with an area of about 80,000 sq. m., and a population of 5,000, is what is called the Gadsden purchase, and is now commonly known as the unorganized territory of Arizona. (See ARIZONA.) The population of New Mexico according to the census of 1850 was 66,547, of whom 66,525 were whites and 22 free colored persons. The Indians number about 44,000 additional.—The Rio Grande, or Bravo del Norte, rises near the N. frontier of the territory on the S. W. border of Kansas, and flows S. E. and S., forming the E. boundary of Arizona, and crossing the frontier between Texas and Mexico. Its tributary, the Pecos, waters the E. part of the territory. The Canadian and some of the head branches of the Arkansas also have their sources here. W. of the Rocky mountains are the Colorado and its tributaries, the Colorado Chiquito or Rio de Lino, San Juan, Virgen, Green, Grand, and Williams Fork; and the Gila with its tributaries, the Rio Verde, San Francisco, and Prieto. The Rio Grande has in the territory a direct course of 500 m., and including windings a length of 1,200 m. In width it varies from 150 to 600 feet, and in dry seasons is nearly all absorbed for purposes of irrigation. The broadest arable valleys lie along this river. The Mesilla valley borders its W. bank; it commences about 10 m. N. of El Paso, and is about 80 m. in length, with a width of from $\frac{1}{2}$ m. to 2 m. The Colorado is the largest river in the territory. Its banks, in many places, where it forces its way through mountains, are very precipitous, rendering it unapproachable. Recent explorations with a steamboat demonstrate that its valleys, mostly covered with timber, are broad and rich, and are capable of sustaining a large population. Artificial irrigation is necessary here, as elsewhere in the territory. Several Indian tribes occupy the valley and cultivate the soil, raising wheat, Indian corn, beans, melons, &c. The U. S. officers who explored this river report that there are about 700 sq. m. of arable land between the mouth of the Gila and the 85th parallel.—The greater portion of New Mexico is mountainous, embracing some of the largest mountain ranges in North America. Among them are the Rocky mountains, and E. of these the lesser chains known as the Sierras Blanca, Organos, Oscuro, Sacramento, and Guadalupe. On the W. side are ranges known as the Sierras Madre, Mogoyon, Burro, Pinal Lleno, Chiricahui, and Santa Rita. N. of the Gila and E. of the Colorado the whole country is intersected by detached ranges or spurs of mountains. The elevation of Santa Fé is 7,000 feet, while

the mountains near, whose peaks are covered with snow, rise to the height of 12,000 feet above the level of the sea.—The climate varies much. Near Santa Fé, and in the mountains, the winter is severe. In the southern portions near El Paso the temperature is mild, being seldom below the freezing point. In the Arizona district, S. of the Gila, snow seldom if ever falls, and frosts are rare. The summers are very hot in this district, the temperature ranging from 90° to 110°, yet the whole territory may be considered very healthy. The sky is generally clear and the atmosphere dry. In the southern portion the rainy season is in the months of July and August. The diseases are few. Inflammations and typhoid fevers sometimes appear in the winter season; rheumatism is more prevalent, arising doubtless from the common practice of sleeping on the ground. Pulmonary complaints are scarcely known.—The agricultural portions of New Mexico are the bottom lands near the rivers and small water courses. The principal of these is the valley of the Rio Grande, which river is the main artery of the territory, rising near its northern boundary and flowing through its entire length. This valley is generally from 1 to 4 m. in width, yet in some places expands to 10 or 15 m. It has a light soil, and by artificial irrigation is very productive; indeed, it is not unusual to raise two crops in the year from the same land. As there is but little rain, artificial irrigation is necessary. This is accomplished by damming the stream, and leading the water by canals and ditches, called *acequias*, over the valleys. Near El Paso is an *acequia* 20 m. in length. The Indians on the Gila also resort to this system of irrigation. Agriculture is carried on in a primitive way, with a hoe and a wooden plough made of a forked tree, such as is used on the plains of Syria and in Persia. By this means only the surface of the soil is disturbed, but it seems quite sufficient for the purpose. The fields are without fences, though many are protected by the ditches, along which bushes spring up, thereby making a hedge. The census of 1850 presents the following statistics of agriculture in New Mexico, not including the Mesilla and Santa Cruz valleys and other districts in what is now called Arizona, that country being then a portion of Mexico. Number of farms, 3,750; acres of improved land, 166,201; unimproved, 124,870; cash value of farms, \$1,653,952; of implements and machinery, \$77,960. The live stock consisted of 5,079 horses, 8,654 asses and mules, 10,635 milch cows, 12,257 working oxen, 10,085 other cattle, 377,271 sheep, and 7,814 swine; value of live stock, \$1,494,629. Wheat raised in 1849, 196,516 bushels; Indian corn, 365,411; peas and beans, 15,688; value of orchard products, \$3,231; of gardens, \$6,679; of cheese, \$5,848; molasses, 4,236 galls.; wool, 32,091 lbs.; tobacco, 8,467 lbs.; wine, 2,363 galls.; value of home manufactures, \$6,033; of slaughtered animals, \$32,125. Little butter is made, and the cul-

thivation of potatoes has not until recently been attended with success. Stock raising is the most profitable source of income, the country being better adapted to this branch of industry than the cultivation of the soil. Immense flocks of sheep are raised, as well as a great number of mules. Portions of the high plains, valleys, and the lesser hills are covered with grass sufficient for the pasturage of millions of animals; and it is not necessary to protect them in the winter. The great and only impediment to stock raising is the incursions of the Indians, when they carry off immense numbers of animals.—The mineral resources of the country are great, yet this branch of industry is much neglected. Gold, silver, copper, iron, and lead are known to exist in abundance. Zinc is also found. Some of the gold placers have long been imperfectly worked, and would give a plentiful yield if in skilful hands; but with bad management the returns are small. Thirty miles S. W. of Santa Fé are rich placers known as the Ortiz, Biggs, and Davenport mines. Mr. Gregg says that from 1832 to 1835, when mining operations were most flourishing, from \$60,000 to \$80,000 per annum was taken from them, and that from their first discovery to 1844 they yielded about \$500,000. The ore exists in quartz, which is easily crushed. At the new placer, which is in the vicinity, the gold is obtained by washing. Near the Placer mountains the whole soil seems to be impregnated with the precious metal, and it is believed by those who have examined this district that it would be one of the richest gold-bearing countries in the world if science and capital were employed in its development. Silver is also found in many parts. In Spanish times several mines were worked to advantage, but at present the only one worked is the Stevenson mine, in the Organ mountains, near Donna Anna. It is also found in the Sandia mountains. Several copper mines were formerly worked. Coal has been found cropping out upon the surface in many places. Salt lakes or *salinas* are numerous in the country, and are chiefly found between the Rio Grande and the Pecos. From these all the salt (muriate of soda) used in New Mexico is procured. Chihuahua also receives its chief supply from the same source. A train of 10 or 15 large wagons, each capable of carrying 5,000 lbs. of salt, goes once a year from El Paso to a salt lake 60 m. distant, E. of the Organ mountains, for the annual supply. Mineral and warm springs, some of which possess rare medicinal virtues, are found in different parts.—The manufactures are blankets, serapes, and a coarse kind of carpets. There are also a number of distilleries in the country. All the merchandise received and sent from New Mexico is by trains of wagons. From St. Louis large trains are sent to Santa Fé with merchandise, which supplies all the northern portion of the territory. The commerce of El Paso and the southern portion is with San Antonio, Texas. The caravans make the northern jour-

ney in from 50 to 60 days; the southern is from 40 to 50 days. Sometimes, when there is a deficiency of grass, they are 20 days longer.—The Indian population may be divided into two great classes: 1, the wild nomadic tribes, and those who live by the chase; 2, the Pueblo or semi-civilized tribes, who live in communities, have fixed places of residence, and cultivate the soil. The former include: 1, the Navajoes; 2, the Apaches, and the various tribes allied to them, among which are the Jicarillas, the Muscaleros, the Coyoteros, the Tontos, the Pinal Llenos, and the Gileños; 3, the Utahs; 4, the Cheyennes; 5, the Comanches. Beside these, other wandering tribes roam over portions of the territory. The number of these Indians within the territory, according to the report of the governor of New Mexico made in 1855, is as follows: Apaches proper, 7,000; Navajoes, 7,500; Utahs, 2,500; Comanches, Cheyennes, and other wandering tribes, 17,000; total, 34,000. The Apaches and their allied tribes extend from the Colorado of California, along both sides of the Gila, to the borders of Texas, Sonora, and Chihuahua. The Navajoes are between the Little Colorado and the river San Juan. The Utahs are in the northern parts, while the Comanches and Cheyennes roam only in the eastern parts bordering on Texas. The second of the great classes of Indians includes the following Pueblo or village tribes, according to the census taken in 1851, by order of Gov. Calhoun: Taos, 361; Picuris, 222; San Juan, 568; Santa Clara, 279; San Ildefonso, 139; Pojodque, 48; Tesuque, 119; Nambe, 111; Zuni, 1,500; Laguna, 749; Acoma, 350; Lentis, 210; Isleta, 751; Sandia, 241; Oia, 124; Santanna, 399; Jemez, 385; San Felipe, 411; Santo Domingo, 666; Cochiti, 254; Moqui Pueblos, according to Gov. Bent, 2,450; total, 10,317. Add those of the first class, 34,000, and the whole number of Indians in the territory is 44,317.—New Mexico was among the earliest of the interior portions of North America visited by the Spaniards; and distant as it is from the sea, the adventurous spirit of that people led them here nearly a century before the English had landed on the shores of New England. Alvar Nunez (Cabeça de Vaca), with the remnant of those who accompanied Narvaez to Florida, reached New Mexico before 1537, and made a report to the viceroy of Mexico of what they saw. The expedition of Marco de Niza followed in 1539, and that under Coronado the next year. The latter traversed the country N. of the Gila occupied by the Pueblo Indians, and pushed his way eastward beyond the Rio Grande to the country of the *cibola*, or buffalo, and is the first who speaks of that animal, which he calls "a new kind of ox, wild and fierce, whereof, the first day, they killed four-score, which sufficed the army with flesh." The great prairies and desert plains of New Mexico are so truthfully described by Castaneda, the historian of the expedition, that no doubt remains of his crossing the entire country. In 1581 other

adventurers under Capt. Francisco de Bonillo reached the country, and on their return made known the mineral wealth existing there, which caused the name of New Mexico to be applied to it. About this period Augustin Ruiz, a Franciscan missionary, entered the country, and was soon after murdered by the Indians. A more successful official of the government was Don Antonio Espejo, who took with him a body of men to protect the missions. The viceroy of Mexico sent Juan de Oñate to take formal possession of the country in the name of Spain, and to establish colonies, missions, and forts there. The year of his arrival is by some writers stated to be 1595, by others 1599. The missionaries met with great success in Christianizing the native tribes. The Pueblo Indians were more ready to adopt the new faith than the roving tribes; and it is a singular fact that on rediscovering some of these Pueblos within a few years, when they had been without any priest for nearly a century, many of the Christian rites and doctrines were found among them, though strangely blended with their own religion. Espejo found the people considerably advanced in civilization. They wore garments of cotton of their own manufacture. Their arms were large bows, and arrows terminated with sharp-pointed stones; their long wooden swords were also armed with sharp stones. They carried shields made of the raw hides of buffaloes. Some of the people lived in stone houses several stories high, the walls of which were ornamented with pictures; these lived in the valleys and cultivated the soil. In the villages were seen a great many idols, and in every house was a chapel dedicated to some evil genius. Oñate is stated by historians to have been the most successful of all the officials sent to New Mexico. Many new missions were established, mines were opened and worked, and the country was in a flourishing state. But the enslavement of the Indians by the colonists, who compelled them to labor in the mines, was too much for them to bear. They made several ineffectual efforts to rid themselves of their oppressors, and finally in 1680 drove out the Spaniards, and recovered the whole country as far south as El Paso del Norte. It was not until after several attempts that the Spaniards regained possession of the country in 1698. In 1846 Santa Fé was taken by a U. S. force under Gen. Kearney, who soon after conquered the whole territory from Mexico. In 1848 it was ceded to the United States by the treaty of Guadalupe Hidalgo; and on Sept. 9, 1850, the present territorial government was established. The territory S. of the Gila (Arizona), acquired from Mexico under the treaty of Dec. 30, 1853, was annexed to New Mexico by act of congress passed Aug. 4, 1854, and still so remains.

NEW MILFORD, a township and village of Litchfield co., Conn., on the left bank of the Housatonic river, and on the Housatonic rail-

road, 85 m. N. by W. from Bridgeport; pop. of the township in 1860, 8,860. The village is neatly laid out with wide streets, and in 1850 contained 4 churches (Baptist, Congregational, Episcopal, and Methodist), a bank, and 2 woolen factories. The town contains 8 grist mills, 2 paper mills, a fulling mill, a cotton factory, and 5 tanneries.

NEW ORLEANS (French, *La Nouvelle Orléans*), the chief city of Louisiana, capital of the parish of Orleans, and the emporium of the Mississippi valley, situated on the left bank of the Mississippi river, about 100 m. from its mouth, in lat. 29° 58' N., long. 90° W.; pop. in 1803, 8,000; in 1810, 17,242; in 1820, 27,176; in 1830, 46,810; in 1840, 102,193; in 1850, 116,375; in 1860, 168,823, of whom 18,880 were slaves. A portion of the increase of the last decade is due to the incorporation with the city of the contiguous town of Lafayette (pop. in 1850, 14,190). The older portion of the city is built on the convex side of a bend of the river, which here sweeps around in a N. E., E., and S. E. course. From this location it derives its familiar sobriquet of the "Crescent City." In the progress of its growth up stream, the city has now so extended itself as to fill the hollow of a curve in the opposite direction, so that the river front presents an outline somewhat resembling the letter S, and 6 or 7 m. in extent. This configuration necessarily renders the direction of the streets very irregular. The whole of southern Louisiana is a vast plain, but the land immediately adjacent to the river is more elevated than elsewhere. There is, therefore, a gradual descent from the river to the swamps lying in the rear of the city, at a distance of half a mile to a mile and a half from the levee. These swamps are covered with a dense growth of cypress trees and underbrush, affording a habitation for multitudes of alligators and other reptiles. Beyond the swamp, bordering on the shore of Lake Pontchartrain, 5 or 6 m. N. of the city, lies a tract of drier and more elevated ground, known as the Metairie ridge. Here are several of the city cemeteries. Bayou St. John, a deep, navigable inlet from Lake Pontchartrain, indents the swamp and extends to the suburbs. The "canal Carondelet," communicating with this bayou, penetrates into the heart of the city, and terminates in a basin for the accommodation of vessels. Most of the coasting trade, however, with the ports of the gulf lying eastward, is now carried on through another canal communicating directly with the lake, to the westward of Bayou St. John. The spacious basin of this canal is at all times filled with sloops, schooners, and other craft, most of which are employed in the lumber trade. Beside these canals, the Pontchartrain railroad, connecting the city with the lake, communicates at its terminus with steamers plying to Mobile and other places on the coast. The Carrollton railroad, from New Orleans to the village of Carrollton, 6 or 7 m. above, has also a branch extending to Lake

Pontchartrain. The Mexican gulf railroad, nearly 80 m. in length, connects the city with Lake Borgne. The most important railroads terminating at New Orleans are the New Orleans, Jackson, and great northern, which unites it with the great railroad systems of the eastern and northern states, and the New Orleans, Opelousas, and great western, extending westwardly toward Texas, and susceptible of indefinite prolongation. The great avenue, however, of the trade and commerce of New Orleans, is the Mississippi river. Along the river front of the city the levee, or artificial embankment, is extended by a continuous series of wooden wharfs or piers. A sort of esplanade is thus formed, several miles in extent, which during the busy season presents a scene of singular variety and animation.—The new custom house of New Orleans is one of the largest and most massive structures in America. It was begun in 1848, and is not yet completed. The estimated cost is \$8,500,000, a large proportion of which has already been spent. It is of granite, built in the form of a trapezium, to adapt it to the streets which enclose it; the dimensions of the sides being, respectively 384, 310, 296, and 251 feet, fronting Canal, New Levee, Old Levee, and Custom House streets. The height of the main building is to be 85 feet to the roof, and 180 feet to the summit of the dome. The principal room is 116 feet by 95 in dimensions, lighted from the dome, which is to be of iron, supported by 14 Corinthian columns of white marble. The branch mint of the United States, situated on Esplanade street, near the site of Fort St. Charles, which stood at the eastern angle of the old city, is of brick, stuccoed, 282 feet by 108, with two wings, each 81 by 29 feet, the whole being 3 stories in height. The architecture is Ionic, and the cost of the building was \$182,000. The coinage, during the year ending July 31, 1860, amounted to \$169,000 of gold, and \$1,438,000 of silver; total, \$1,607,000, being a considerable reduction from the operations of previous years. New Orleans has about 60 churches and places of public worship, of which 2 are Baptist, 8 Episcopal, 8 Jewish, 4 Lutheran, 13 Methodist, 7 Presbyterian, 20 Roman Catholic, 1 Unitarian, &c. Of all these the most celebrated is the cathedral of St. Louis, a noble Gothic edifice, which stands on the site of the original parish church, fronting Jackson square, formerly the Place d'Armes. The present building was erected in 1850. Its façade is flanked by two lofty towers. St. Patrick's, St. Joseph's, St. Augustine's, and the new churches of St. Mary and St. Alphonsus, are all fine specimens of ecclesiastical architecture. St. Paul's and Christ churches (Episcopal), the 1st Presbyterian, the Unitarian, and several Roman Catholic churches beside those above mentioned, are all worthy of note.—Foremost among the benevolent institutions is the charity hospital, supported partly by the state, partly by the city, and partly by various endowments.

Among the earliest and most liberal of its benefactors was Señor Roxas, who, about 1786, erected a building (afterward consumed by fire) at an expense of \$114,000, and endowed it with a revenue of \$1,500 per annum. The present edifice, erected about 1812, accommodates 400 or 500 patients, and is attended by sisters of charity. The sisters have another infirmary or *maison de santé*, with 100 or 150 patients. The ladies of Providence have an asylum for infirm old men and an asylum for widows. Stone's hospital, the Franklin infirmary, and the U. S. naval hospital are the principal other establishments for the care of the infirm. Beside many other charitable institutions, there are 6 Roman Catholic orphan asylums, one of which has a country house at Carrollton for sick and delicate children, while another is also an industrial school. One of the most interesting of the benevolent foundations is the Hebrew benevolent association, which was liberally endowed by the late Judah Touro, an eminent merchant of New Orleans.—The public school system of New Orleans was inaugurated in 1841, and has been conducted with great success. The schools are governed by a separate board of directors and superintendent for each of the 4 districts; the directors being elected annually by the city council, and the superintendents by the directors of each district, respectively. In connection with the schools of the 1st and 2d districts are valuable public libraries; that of the 1st district contains more than 11,000 volumes. Both of them include some rare and valuable works. Beside these, there are numerous private schools, two well supported and flourishing medical colleges, a Roman Catholic ecclesiastical seminary, a college under the Jesuits, a convent and academy of Ursuline nuns, free schools directed by members of several religious orders, male and female, and a convent of Redemptorists. There are 10 daily newspapers; 1 commercial, 1 literary, 4 religious weeklies; 2 medical journals; and "De Bow's Review," a monthly commercial, industrial, literary, and miscellaneous repository. One of the daily journals is exclusively German; one of the religious weeklies is French; and two of the dailies are both French and English. The other journals and periodicals are printed in English. The great comparative cost of printing and other labor operates as a severe restriction upon periodical literature in New Orleans and the South-West generally.—The principal theatres are the *théâtre d'Orléans*, the elegant new opera house opened in 1859, and the St. Charles and varieties theatres. Of the hotels, the St. Louis, which extends 300 feet on St. Louis street, from Chartres to Royal, with a depth of 120 feet on each of the last two streets, is celebrated for its magnificent rotunda, the ceiling of which is richly adorned with paintings. The St. Charles is one of the most imposing edifices in the city. It was destroyed by fire a few years ago, and re-

built in 1852, at a cost of about \$590,000. The St. James, opened in 1860, and the city hotel, are also spacious and elegant buildings. Among other public buildings worthy of note, not already mentioned, are the Odd Fellows' hall, municipal hall, bank of Louisiana, canal bank, U. S. marine hospital in the village of McDonough opposite the city, and the U. S. military barracks about 8 m. below. Some of the largest and most costly structures are the vast cotton presses. The Orleans press occupies a space of 632 by 308 feet, most of which is covered with buildings. It has storage for 25,000 bales of cotton, and compresses on an average about 150,000 bales per annum. The cost of the ground and buildings was \$753,000. The Levee press cost \$500,000.—The streets, shops, and dwellings of New Orleans present an extraordinary variety of style and construction. The limits of the old city, as it existed under the French and Spanish governments, are defined by Canal, Rampart, and Esplanade streets. These three streets, occupying what was formerly the line of the defensive works, are nearly 200 feet in width, with a sidewalk and carriage way on each side, and in the middle an unoccupied space (or "neutral ground," as it is called) planted with a double row of trees. Within the above limits the streets are narrow, crossing each other at right angles, the houses compactly built, but without uniformity, and the whole presenting the appearance of a European city. Many of the dwellings are constructed with a carriage way and gate opening directly from the street to an interior courtyard enclosed by the main building. Most of the signs over the shops are inscribed in French, or both French and English. This portion of the city, with the old faubourg Trémé in its rear, constitutes the 2d district, formerly the 1st municipality. Next above, extending from Canal street to Felicity road, lies the 1st district, formerly the faubourg St. Mary, and subsequently the 2d municipality; while still beyond is the 4th district, prior to 1852 the city of Lafayette. In these two districts the buildings are more modern, and most of the streets are wider, though very irregular in their directions. In the 4th district many of the dwellings are spacious and of great elegance, with ample grounds for shrubbery, &c. Below the old city again lies the 3d district, formerly the faubourg Marigny, and afterward the 3d municipality, which is the residence of a large portion of the creole and foreign population. The nomenclature of the streets is remarkable. French, Spanish, and Anglo-American ideas and personages are all represented. The 9 Muses, with other heathen divinities, give name to one series, while in other quarters are found St. Charles, St. Mary, St. Louis, St. Andrew, St. John Baptist, St. Paul, St. Peter, and the like, together with "Love," "Piety," "Religious," "Virtue," &c. The Pontchartrain railroad, by which the traveller arrives from the eastward, runs through the Elysian fields—a

street, and by no means the most attractive one of the city. "Greatmen," "Goodchildren," "Frenchmen," "Craps," &c., are specimens of other odd and apparently whimsical names. The same street repeatedly changes not only its direction, but its designation. Thus Royal, one of the original streets of the old city, becomes St. Charles on entering the 1st district, and still higher takes the pagan and poetical name of Náyades; while its continuation in the opposite direction, through the 3d district, commemorates the marquis Casa Calvo, the last of the Spanish governors. In like manner Bourbon becomes Carondelet and then Apollo in one direction, and declines into Bagatelle in the other. An effort has been recently made by the city authorities to correct many of these irregularities. There are 5 or 6 public squares in New Orleans. Jackson square, formerly the Place d'Armes, is coeval with the foundation of the city. It is tastefully adorned with shrubbery and statuary, prominent amid which, in the centre of the square, is a bronze equestrian statue of Gen. Jackson, by Clark Mills. Lafayette square, in the 1st district, is well shaded, and affords a delightful summer promenade. The present Place d'Armes is Circus place, or Congo square, so called from the fact of its having formerly been a favorite resort of the negroes for dancing and other amusements. A colossal statue of Henry Clay, by Hart, was inaugurated April 12, 1860. It is of gilt bronze, and stands on the "neutral ground" in the centre of Canal street. The markets of New Orleans, of which there are 7, are among the most interesting fields for observing the peculiarities of creole life and habits. The "Old French Market" (as it is popularly known) of the 2d district is the most extensive and characteristic.—The population of New Orleans has long been remarkable for the diversity of its elements. About one half of the whites are of foreign birth, and among these the French and Spanish are predominant. The Irish and Germans are also numerous. The English and Scotch are few in proportion, and are chiefly connected with the foreign commerce as merchants or factors. Sir Charles Lyell says, describing the markets of New Orleans: "When passing through the stalls we were surrounded by a population of negroes, mulattoes, and quadroons, some talking French, others a patois of Spanish and French, others a mixture of French and English, or English translated from French, and with the French accent. They seemed very merry, especially those who were jet-black. Some of the creoles also, both of French and Spanish extraction, like many natives of the south of Europe, were very dark." The same traveller describes the French creole ladies as very handsome, usually not so thin as are the generality of American women, and as dressing in Parisian fashion, "their luxuriant hair tastefully arranged, fastened with ornamental pins, and adorned with a colored ribbon or a single

flower."—There are about 17 cemeteries in and around the city. The soil being so moist and marshy that interment beneath the surface is objectionable, the usual mode of sepulture, whenever the expense can be incurred, is in tombs above ground. Many of these are of costly and elegant construction. The walls of these enclosures are about 10 feet in thickness and 12 in height, and are completely honeycombed with arched cells, just large enough for the reception of coffins endwise. The mouth of the cell, when occupied, is hermetically closed. On All Saints day (Nov. 1) the Roman Catholic cemeteries, and the others to some extent, are resorted to by great crowds of visitors, as it is then customary to visit the tombs of deceased relatives and friends, and adorn them with wreaths, bouquets, and other offerings. New Orleans, during the first 70 or 80 years of its existence, seems to have been regarded as eminently healthful. The unacclimated were subject to slight fevers, which were rarely fatal. De Lozières, a French traveller, who was in Louisiana from 1794 to 1798, speaks of it as follows: "New Orleans is an enchanting place of abode. The air there breathed is so wholesome, the earth so fruitful, the location so delightful, that we might fancy ourselves in the midst of a flower garden. It is on the banks of the Mississippi—those banks so favored by nature; and its pure and pleasant waters are said to possess the property of contributing even to the multiplication of the human race." Such was the general tenor of the descriptions given of it during the 18th century. Since its transfer to the American government, the repeated ravages of yellow fever have given it a very different reputation. It appears, nevertheless, to be well established that, apart from yellow fever, the healthfulness of New Orleans is not surpassed by that of any large city, and that, including all risks, the natives and thoroughly acclimated residents compare favorably with any other community in respect of health and longevity. The generally received statement is that yellow fever first appeared in this city in 1769, the same year in which O'Reilly took possession in the name of the Spanish crown. Dr. Bennet Dowler, however, who has bestowed much research upon the subject, believes that its first appearance was in 1796. On either supposition its occurrence was long subsequent to the prevalence of the disease in other cities of Europe and North America. It prevailed with some severity in 1799, and has repeatedly ravaged the city during the present century. Some of the most memorable epidemics were those of 1819, '22, '29, '33, '35, '37, '39, '41, '43, '47, '53, and '58. In 1853, out of a population supposed to be reduced to about 120,000, the whole number of deaths during a period of 150 days—from May 26 to Oct. 22, inclusive—was 11,156, of which about 8,500 were attributed to yellow fever. The greatest number of deaths in any one day was 283, on Aug. 22. Even in this fatal season the natives

and older residents were to a great extent exempted, most of the mortality occurring among strangers and foreigners. From fear of epidemics and the general relaxation of business, the population is much reduced during the months of July, August, September, and October.—The water of the Mississippi was introduced into the city for domestic uses in 1836. The works were constructed under the direction of Albert Stein, at a cost of about \$400,000. The reservoir, occupying the space between Richard, Market, St. John Baptist, and Religious streets, is 250 feet square, divided into 4 compartments, and surmounted, at the intersection of the partition walls, by a handsome pavilion. Its capacity is 4,000,000 gallons, and it is supplied by pumps worked by a steam engine. The average daily delivery in 1859 was about 6,000,000 gallons, and the number of buildings supplied about 8,000. Most of the dwellings are also provided with large cisterns for rain water. The streets of New Orleans were almost entirely unpaved until within 80 or 40 years past. The nature of the soil rendering it very difficult to keep an ordinary pavement in repair, the authorities are now (1861) engaged in paving the principal streets with large blocks of granite. A company has been chartered, with a capital of \$1,000,000, for the construction of a network of street railroads, and a portion of the work is accomplished. This company holds the exclusive privilege for 25 years, for which it pays the city the sum of \$130,000. Among other recent improvements is a police and fire-alarm telegraph, by means of which instant communication may be held between the central police office at the city hall and every part of the city.—The city government consists of a mayor, board of aldermen, and board of assistant aldermen. Each district has its own recorder, who holds a court for the trial of offences against the municipal laws. The executive police, however, is under the immediate control of the mayor.—The villages of Algiers, McDonough, and Gretna, on the opposite side of the Mississippi; Jefferson City, immediately above the 4th district; Carrollton, a few miles beyond; and Milneburg on Lake Pontchartrain, at the end of the Pontchartrain railroad, are dependencies of New Orleans. Algiers has a considerable population, extensive docks for the construction and repair of vessels, some manufactories, several churches, &c. Gretna has some neat and tasteful dwellings. The "stock landing" and depot of cattle for the New Orleans market is in Jefferson City. During the year 1859-'60 the receipts here were 24,095 western cattle, 32,518 Texas cattle, 3,066 milch cows, 25,659 "veal cattle," 30,922 hogs, and 51,294 sheep.—The trade of New Orleans did not for some years keep pace with the increase of population. On the contrary, from 1806 to the close of the war of 1812-'15, there was a considerable decline. In 1802, the year previous to the transfer from France, the ex-

ports amounted to 40,000 tons, of which the principal articles were as follows: 50,000 barrels of flour, 3,000 barrels of salt beef and pork, 2,000 hogsheads of tobacco, 4,000 hogsheads of sugar, 34,000 bales of cotton, and 800 casks of molasses. The trade with the interior was carried on by about 500 flat boats. New Orleans is now the second city in America in the amount and value of its exports, the greatest cotton market in the world, and far beyond all other cities in the number of steamboats employed in its trade. The following table exhibits the annual value of exports from 1805 to 1820, inclusive:

to 1833, inclusive, the average value of exports was about \$14,000,000, and the average value of imports was nearly \$7,000,000. From 1834 to 1842 the average values of exports and imports were, respectively, about \$33,000,000 and \$12,500,000. From 1843 to 1850 the average of exports rose to nearly \$40,000,000, while that of imports declined to \$9,000,000. The following is a statement in detail for the last 10 years, the annual amount being made up for the 12 months ending with June 30 of each year:

Since 1820 the increase of trade has been more steady. From 1821 to 1824, inclusive, the average annual value of exports was about \$7,750,000; of imports, about \$4,000,000. From 1825

The following table exhibits the value of southern and western produce received at New Orleans for the last 12 years, ending with Aug. 31 of each year:

Years.	Cotton.	Sugar.	Molasses.	Tobacco.	Other products.	Total.
1840.....	\$30,844,314	38 00	02 00	01 50	\$28,153,928	\$81,009,002
1850.....	41,885,150	12 50	2 00	6 00	34,049,173	96,897,573
1861.....	48,756,764	12 80	2 00	7 00	35,127,530	106,924,063
1862.....	48,692,222	11 60	4 00	7 85	36,400,951	106,051,706
1863.....	68,759,424	15 88	3 00	7 50	37,442,973	134,233,785
1864.....	54,749,602	15 40	3 00	4 00	36,912,756	115,336,796
1865.....	51,390,720	18 20	4 00	7 70	36,424,713	117,106,823
1866.....	70,371,720	16 90	4 42	7 00	46,119,429	144,256,051
1867.....	86,255,079	8 00	2 00	11 20	49,091,510	158,061,309
1868.....	88,127,340	17 08	4 05	12 27	42,798,250	167,156,546
1869.....	92,037,794	24 24	6 17	9 50	40,283,879	172,952,054
1860.....	109,389,228	18 80	6 35	8 85	42,663,326	165,211,254

The next table exhibits the share of New Orleans in the cotton trade of the country, giving the receipts and exports, and also the whole crop of the United States, in bales, for 25 years:

ceipts and exports of the principal articles of produce during the year ending Aug. 31, 1860:

Articles.	Receipts.	Exports.
Cotton, bales.....	2,255,458	2,214,315
Tobacco, hhds.....	81,068	82,168
Sugar, hhds.....	175,219	45,626
Molasses, barrels.....	312,848	119,687
Flour, barrels.....	932,174	879,926
Indian corn, sacks.....	1,702,847	649,889
Pork, barrels and tierces.....	212,820	51,468
Pork, in bulk, lbs.....	5,379,666
Beef, barrels and tierces.....	25,119	22,775
Bacon, hhds. and casks.....	42,686	23,146
Hams, casks and tierces.....	35,127	14,767
Lard, barrels and tierces.....	57,014	24,377
Lard, kegs.....	86,587	61,019
Whiskey, barrels.....	185,098	63,929
Hides.....	159,129	137,101
Lead, pigs.....	81,992	82,896

To which may be added the following statement of various articles received, chiefly for city and plantation use:

Oats, sacks.....	647,898
Hay, western, bales.....	154,190
Hay, northern and eastern, bales.....	59,485
Bagging, Kentucky, pieces.....	94,419
Star candles, boxes.....	112,129
Apples, barrels.....	50,297
Bale rope, coils.....	195,796
Butter, western, kegs, &c.....	28,001
Cheese, western, boxes.....	34,189
Lard oil, barrels.....	9,390
Coal, western, barrels.....	1,979,004
Potatoes, western, barrels.....	290,183

It is to be observed that there has been a gradual increase in the average weight of the cotton bale during the period covered by the above table. The annexed statement shows the re-

The receipts at the custom house of cash duties on imports for 8 years, each ending June 30, were as follows: 1853, \$2,158,172; 1854, \$2,647,386; 1855, \$2,181,001; 1856, \$3,548,341; 1857, \$3,595,420; 1858, \$2,084,554; 1859, \$2,103,062; 1860, \$2,620,665. The principal imports in 1859-'60 were: West India sugar, 8,129 hogsheads, 16,914 boxes and barrels; Brazil sugar, 332 bags; Cuba molasses, 17,419 hogsheads and tierces, 5,604 barrels; Liverpool salt, 848,327 sacks; Sicily salt, &c., 871,182 bushels; Rio coffee, 280,926 bags; Cuba coffee, 4,615 bags. The number of entrances and clearances of sea-going vessels has varied but little for 10 years past, averaging a little more than 2,000 per annum; but the aggregate tonnage has advanced from 768,000 in 1850-'1 to more than 1,200,000 in 1859-'60, showing a progressive increase in the size of the vessels employed. For the year ending June 30, 1860, the entrances were 2,052, with a tonnage of 1,212,029; the clearances 2,385, with a tonnage of 1,248,526. Of the arrivals, about 800 were of steamships. The arrivals of steamboats for the year ending Aug. 31, 1860, were 8,566; of flat boats, 831. The greatest obstruction to the commerce of New Orleans arises from the bars existing at the mouths of the Mississippi, occasioned by the immense amount of sedimentary matter brought down and deposited by the river. These bars vary in position and in the depth of water upon them, almost every freshet occasioning some change in these respects. Various efforts have been made, at great expense, by dredging and other means, to deepen the water and obtain a channel of sufficient depth, but thus far none have been permanently successful.—The banking system of New Orleans is regarded as one of the best in existence. The number of banks is 11, with an aggregate capital of \$18,087,300. The dividends paid by these banks during the year ending Aug. 31, 1860, amounted to \$1,991,180. There are 11 insurance companies, with an aggregate of capital and assets amounting to \$8,409,816. The premiums earned by these companies during the year amounted to \$4,984,470, and the losses paid to \$3,408,498.—The first settlement was made at New Orleans in 1718, under the direction of Bienville, then governor of the French province of Louisiana, who had become convinced of the propriety of removing the chief seat of the colony from Mobile to the more productive region lying on the Mississippi. Charlevoix, who visited it in 1722, speaks of it even then as "this famous town which has been named New Orleans." He expresses his disappointment, however, on finding it really to consist only of "a hundred cabins, disposed with little regularity; a large wooden warehouse; two or three dwellings that would be no ornament to a French village; and the half of a sorry storehouse, which they were pleased to lend to the Lord, but of which He had scarcely taken possession when it was proposed to turn Him out to lodge under a tent." He

goes on, nevertheless, to make the prediction that "this wild and dreary place, still almost entirely covered with woods and reeds, will, one day (and perhaps that day is not far distant), be an opulent city and the metropolis of a great and rich colony." The population at this time consisted of about 200 persons.—In 1728 Bienville removed his head-quarters from Mobile to New Orleans, and the seat of government was permanently transferred. On Sept. 11 of the same year occurred a frightful hurricane, which destroyed the church, hospital, and three ships that were lying in the river, beside doing immense damage to the crops in the adjacent country. In 1726 Bienville was superseded by Périer, one of the earliest acts of whose administration was the construction (1727) of a strong levee, more than a mile in length, in front of the city, which had previously been subjected to annual overflows from the river. Smaller levees were also extended for about 15 m. above and the same distance below, and a deep ditch or canal was dug around the city. About the same time arrived a colony of Jesuits and one of Ursuline nuns, sent out by the western company to take charge of the spiritual interests of the colony. Grants of land and other property were made to each of these societies, and a building was erected for the use of the Ursulines, which was occupied by them from 1730 to 1824, and which is still known as the "old Ursuline convent," being probably the oldest edifice in existence in Louisiana. It is now occupied as a residence for the Roman Catholic archbishop. The Ursulines have erected a spacious and handsome building 2 or 3 m. below the city, devoting themselves chiefly to female education. The Jesuits established themselves just above the city, in what is now the 1st district, where they continued to reside until expelled from the colony in 1768. The following description of New Orleans, by Le Page du Pratz, probably applies to a period some 10 or 12 years subsequent to that quoted above from Charlevoix: "In the middle of the city, facing the river, is the Place d'Armes. Midway of the rear of this square is the parish church, dedicated to St. Louis, where officiate the reverend father Capuchins; their residence is on the left of the church; on the right are the prison and guard house. The two sides of the square (*place*) are occupied by two sets of barracks. The square is entirely open on the side next the river. All the streets are regularly laid out in length and width; they cross each other at right angles. These streets divide the city into 66 squares (*sales*), 11 in length along the river, and 6 in depth. These squares measure 50 toises (about 320 feet) each way, and are each divided into 12 lots." Bienville was reappointed governor of the colony in 1733, and continued in office until 1741. He was followed, in succession, by Vaudreuil, Kerlérec, D'Abbadie, and Aubry. During this period of French occupation the progress of New Orleans appears to have been steady,

though very gradual. In 1745 the population was estimated at about 800 white inhabitants, exclusive of women, children, and 200 soldiers, beside 800 negroes. In 1763 the city of New Orleans, with the rest of the colony of Louisiana, was ceded to Spain. Such, however, was the aversion of the inhabitants to the transfer, that it was not until 6 years afterward that the Spanish government actually obtained possession. At this time the whole population was 3,190, of whom 1,808 were free whites, 81 free blacks, 68 of mixed blood, 1,225 negro slaves, and 60 domesticated Indians. The whole number of houses was 468. The city and colony declined somewhat during the brief and rigorous administration of O'Reilly, the first Spanish governor, many of the best inhabitants removing to the West Indies and elsewhere, but revived under the government of a series of moderate and judicious successors. In 1785 a census taken by order of Gov. Galvez exhibited a population of 4,980 souls. On March 21, 1788, a terrible conflagration occurred, by which 900 houses were destroyed, with a vast quantity of property of every description. Provisions became very scarce, and the inhabitants were threatened with famine. Nevertheless the population, according to a census taken in the course of the same year, amounted to 5,338. The administration of the baron de Carondelet (1792-'7) was marked by various improvements, among which were the lighting of the streets, the organization of fire companies, and the opening of the canal Carondelet. He also erected new fortifications around the city, and organized a militia force of about 700 men. During his administration (in 1794) the first newspaper, the *Moniteur*, was issued. A new impetus was given to the trade of New Orleans in 1795 by the treaty of Madrid, between Spain and the United States. At the time of the transfer of Louisiana to the United States, in 1803, the population of the city was about 8,000. Its limits at that time comprised only a portion of what is now the 2d district. It was bounded by Canal, Rampart, and Esplanade streets, and the river, forming nearly a rectangle, defended by 4 strong forts, one at each corner. The faubourgs (or suburbs) St. Mary, Marigny, Trémé, &c., now comprising some of the most wealthy and populous portions of the modern city, were then little more than wild meadows and marshes. The most memorable event in the history of New Orleans, since its transfer to the United States, is the battle on Jan. 8, 1815, for an account of which see JACKSON, ANDREW. Gas was first employed for lighting the streets in 1834, through the enterprise of James H. Caldwell, Esq. In 1836 the city was divided by an act of the legislature into three municipalities, each with a separate government; but in 1852 these municipalities were consolidated, and the limits of the corporation were extended to include the town of Lafayette, lying in the adjacent parish of the same name. The 1st, 2d, and 3d muni-

cipalities are now, respectively, the 2d, 1st, and 3d districts, while the former city of Lafayette constitutes the 4th district.

NEW PHILIPPINES. See CAROLINE ISLANDS.

NEW PROVIDENCE, one of the Bahama islands, lying near the centre of the group, and containing Nassau, the seat of government; pop. in 1851, 8,385. It is 17 m. long from E. to W., and 7 m. broad. It was colonized by the English in 1629, and twice taken from them by the Spaniards, but finally restored at the peace of 1783. It is more hilly than most of the other islands of the group, has some fertile land, and produces good fruits.

NEW SOUTH WALES, a British colony occupying the S. E. part of Australia, stretching along the S. Pacific ocean from Cape Howe to the vicinity of the Solitary islands, bounded N. by the colony of Queensland, E. by the Pacific, S. by the colony of Victoria, and W. by the interior territory of the colony of South Australia. It extends between lat. 30° and 37° 30' S., and long. 141° and 153° E., or about 750 m. E. and W. and 500 N. and S.; area, nearly 300,000 sq. m.; pop. on Jan. 1, 1858, 305,487 (171,673 males and 133,814 females), according to the official statement, but actually estimated at 326,000; and amounting in 1860, at the average annual rate of increase of 15 per cent., to nearly 450,000. The colony of Queensland, extending from lat. 26° to 30° S., was formerly the Moreton Bay district of New South Wales, and was separated from the latter colony in June, 1859; but as this separation is scarcely yet completed, we shall treat the two under the name of the parent colony. This immense territory, comprising altogether about 500,000 sq. m., is divided into 68 counties and several squatting districts. The counties lie along the whole length of coast, extending for about 180 m. into the interior; and the country which they occupy has been thoroughly surveyed and explored, and more or less occupied by settlers. Beside Sydney, the capital, there are several towns of considerable importance on the coast and in the interior, the chief of which are E. and W. Maitland, Liverpool, Bathurst, Goulburn, Windsor, Newcastle, Yass, Penrith, Woolongong, and Paramatta.—The coast line presents in general bold perpendicular cliffs of sandstone, occasionally interrupted by low sandy beaches, some of which stretch a considerable distance inland, and appear to have been covered by the sea at no very remote period. There are numerous bays and indentations along the shore, some of which form excellent harbors. Hervey bay is a very extensive sheet of water at the N. boundary, and next to it in extent is Moreton bay, formed between the mainland and Moreton and Stradbroke islands, the two largest of the colony. Proceeding to the S. from this point there is no important opening for 800 m.; but beginning at Port Stephens there is a succession of harbors, some of them already forming considerable

commercial emporiums. The most important of these are Port Hunter, Port Macquarie, Broken bay, Port Jackson, Botany bay, Port Hacking, Sussex haven, and Jarvis and Two-fold bays.—A mountain range, varying in height from 3,000 to 6,000 feet, extends from N. to S. nearly parallel to the coast, at the distance of from 30 to 50 m. inland, and is called the Liverpool range in the N., in the centre the Blue mountains, and at the S. the Australian Alps. The space between the mountains and the sea has an undulating wooded surface, broken here and there by spurs and ramifications from the mountain range, and in some places covered with dense brushwood. The ground to the W., instead of descending rapidly, continues rugged and mountainous for a considerable width, and at last assumes the form of an elevated plateau, a great part of which remains unexplored. Several considerable rivers rise on the W. side of the mountains and flow westward; but as they have only the first part of their course in New South Wales, they do not properly belong to it. The more important of these rivers are the Murrumbidgee, Lachlan, Bogan, Macquarie, and Peel. The rivers on the E. of the mountain range are mostly small, and many of them are dry during part of the year. The chief are the Hunter, Hawkesbury, George, Shoalhaven, and Clyde. In the N. are the Hastings and Clarence.—The prevailing rock on the E. side of the mountains is sandstone, and on the W. granite. Much of the sandstone belongs to the carboniferous system, and there are several workable seams of good coal. The Newcastle field on the Hunter river is excellent in quality, and contains 5 seams, 2 of 5 feet and 3 of 3 feet in thickness. This field is worked extensively, and the produce, after supplying colonial demands, is shipped to India, China, and California to supply steamers. Several other fields are known, and one is worked at Woolongong. Iron ore is found in many places, and some of it has been smelted by a company formed for the purpose. Rich copper ore is abundant in and around Wellington district. Fine pebbles are so plentiful in the Hunter river, that it is supposed in some part of its course to flow over rocks of jasper, agate, opal, and chalcodony. All these, however, were regarded as comparatively unimportant after the discovery of rich deposits of gold in May, 1851. Gold has since been found in numerous places throughout the colony, and in the territories both N. and S. of it. Near the frontiers of Victoria, particularly in the counties of Wellesley and Wallace, it occurs in several localities; and N. of these it is met with in more than 9 other counties, and is found on the banks of the Macquarie and Meroo rivers. There are considerable deposits about the Peel and its tributaries, and also upon the Fitzroy river somewhat beyond the N. frontier. Australia being in the S. hemisphere, the seasons are the reverse of ours; December is there mid-summer, and June the depth of winter. Summer

extends over December, January, and February; and the mean heat during these 3 months is about 80° at noon. This heat, however, is tempered by the sea breeze, which begins to blow regularly along the coast about 9 in the morning, and continues till evening. The whole colony is subject to hot winds, which are liable to happen 3 or 4 times during the summer, and which blow from the N. W., raising the thermometer to 125° when exposed to their influence. These winds seldom last longer than a few hours, and are succeeded by a very heavy squall from the S., generally accompanied by thunder and rain, cooling the atmosphere immediately. At Sydney the average annual temperature is 64°; that of spring being 65°, of summer 72°, of autumn 66°, and of winter 55°; showing an annual average range of the thermometer of 17°. The temperature of the country above the mountains, however, is much lower, and at some places snow falls in winter. The annual fall of rain is 52 inches at Port Jackson, and 62 at Port Macquarie. Droughts are frequent. The climate is, however, both healthful and agreeable, and its influence is highly beneficial in consumptive diseases.—For 5 or 6 m. from the sea coast the country is in general barren, the soil being mostly composed of drift sand covered with a stunted vegetation. Some rich and fertile districts, however, occur at intervals. Further inland well wooded and fertile valleys lie between the hills, but the land on the E. side of the Blue mountains is as a general rule much inferior in quality, both for agriculture and pasture, to that on the W. Above the range it consists of a dry black soil, covered with open forests and luxuriant herbage. Wheat, barley, oats, rye, various grasses, maize, tobacco, and small quantities of cotton, are all profitably cultivated in different parts of the colony; and potatoes, cabbage, carrots, parsnips, turnips, peas, beans, cauliflowers, lettuces, cucumbers, pumpkins, sweet potatoes, yams, and plantains thrive remarkably well. At Sydney the market is supplied with green peas all the year round; very few vegetables degenerate, and many are more productive than elsewhere. Peaches, apricots, nectarines, loquats, oranges, pears, plums, figs, pomegranates, raspberries, strawberries, mulberries, and melons attain great perfection. The N. districts produce pineapples, bananas, guavas, lemons, citrons, and various other tropical fruits, while W. and S. of Sydney the apple, currant, gooseberry, and cherry are found to grow well. More than 1,000 acres are planted with the vine, and the grapes are of the finest quality. About 50,000 sq. m. of pasture land is occupied by flocks and herds. In 1855 there were 157,159 horses, 1,858,408 horned cattle, 68,091 swine, and 8,608,499 sheep; and a recent estimate based upon official returns of the ratio of increase of the latter since then, makes the number of sheep within the territory in 1860 considerably over 10,000,000. The climate is particularly well suited to all

these animals. Horses are exported in large numbers to India, both for private use and to supply the cavalry and artillery; horned cattle grow to an immense size; and the wool of the sheep is of very superior quality. Asses, mules, and goats are seldom seen. The camel has been introduced for exploring purposes, but has not thriven. About 800 head of llamas, alpacas, and vicuñas have lately been introduced. They were procured with great difficulty, and exported from Peru notwithstanding the rigid prohibitions of the government of that country. High expectations are formed of these animals, which it is thought will exert great influence on the wool trade of Australia, as the fleece of the alpaca weighs from 10 to 12 lbs., while the colonial sheep yields an average of about 2 lbs. The mountains of New England, between Sydney and Moreton bay, are said to have a climate similar to the American Cordilleras, where the family of the llamas are found. Domestic fowl of every description, and some that are delicate elsewhere, thrive remarkably well, and are reared at small expense. Fish are abundant on the coasts; and there is a kind of fresh water codfish in the Murray river which weighs sometimes as much as 70 lbs. Oysters are plentiful, and turtle are procured from the waters of the N. part of the colony.—According to the census of 1856, barely a third of the population of New South Wales was born in Australia; about 75,000 were supplied by England and Wales, 50,000 by Ireland, 16,000 by Scotland, 5,000 by Germany, and 2,000 by China. The population now (1860) includes a large portion of Chinese, many Americans, and some of almost all European nationalities. In appearance and character the native-born part of the community is said to bear a strong resemblance to those of Anglo-Saxon descent in the United States. Since the first establishment of the colony in 1787, the total number of convicts sent into it from Great Britain up to 1840, when the importation ceased, was 54,888. In 1848 the whole population of both New South Wales and Port Phillip (Victoria) was 165,541. At present probably the number of convicts remaining is less than 14,000, while the population of New South Wales and Victoria, taken together, is not much short of 1,000,000; or in other words, the number of actual convicts is only about 1 in 70 of the population. The descendants of felons, however, are much more numerous; but education has been of late years much attended to, and many whose progenitors came to New South Wales as prisoners are intelligent and estimable members of the community. Some of the emancipists, and several of their descendants, are among the most wealthy people in the colony; but the former are never, and the latter but rarely, admitted into the better class of society. The gold fields, however, now attract such an influx of settlers that these caste distinctions must soon disappear, by the convict element being entirely absorbed in the free population.—Much of

the soil of New South Wales is very fertile; but the cultivation is slovenly, and it is only lately that machines have been introduced calculated to economize labor and increase the amount of production. At present the principal attention of the colonists is turned to the produce of the pasture lands, chiefly in the form of wool, hides, and tallow. In 1857, 17,044,201 lbs. of wool were exported. Wines of very superior quality are made, resembling Sauterne, Barsac, hock, claret, &c.; and the culture of the grape promises to become one of the most important interests of the colony. The chief manufactures are leather, and a kind of woollen cloth called "colonial tweed," which is exceedingly durable and in high favor among the settlers. Sugar refining is carried on to a considerable extent at Sydney; and there are extensive distilleries, breweries, various sorts of mills, founderies, tallow boiling establishments, and docks, in different places throughout the colony. The people are, however, dependent upon older countries for clothing, the articles of domestic use and ornament, and those luxuries which can only be produced to advantage where labor is abundant and cheap.—The imports in 1857 were valued at £6,729,408, of which £5,511,007 were from the United Kingdom and the British colonies, and the rest from various countries, including articles amounting to about £800,000 from the United States, consisting of tobacco, timber and pine planks, furniture, agricultural implements, clocks, tubs, pails and brooms, steam machinery, hardware, books, daguerreotype plates, and breadstuffs. The exports in the same year amounted to £4,011,952 (about £600,000 more than in 1856), of which £3,676,418 were to the United Kingdom and British colonies, including wool to the value of £1,275,067; tallow, £82,184; skins, £112,808; and gold dust, £187,249. Beside these chief items of export, there were gums, bark, copper ore, timber, and a large number of minor articles of raw produce. The remarkable difference that appears between the amount of imports and exports is occasioned by the quantity of gold which is coined at the Australian mint at Sydney, and which leaves New South Wales for circulation in the neighboring colonies, and as a remittance to other parts of the world, without appearing among the exports, and by the large numbers of horses, horned cattle, and sheep driven across the frontier to find a market in Victoria. Gold in its natural state is subject to a duty of 2s. 6d. an ounce upon leaving the colony, and so appears in the custom house returns; but the coined gold, having already paid this tax in the shape of mint charges, is allowed to pass unnoticed. Some of the imports from the neighboring colonies, the whole produce of the whale fisheries, and the greater part of what is received from the South sea, are merely transhipped in the ports of New South Wales while *in transitu* to other parts of the world. In 1857, 1,100 vessels of 851,418 tons entered the

port of Sydney, and 1,204 of 377,147 tons cleared. Of these arrivals and departures, nearly $\frac{1}{2}$ were under the British flag. In 1858, 78 American vessels arrived with goods valued at \$7,922,855, nearly \$2,000,000 of which came from the United States, in the proportion of $\frac{1}{4}$ from the Atlantic side, and $\frac{1}{4}$ from the Pacific. The value of the exports to the United States during the same period was about \$48,000.—A railway was projected in 1846 to connect Sydney with the capital of the neighboring colony of Victoria. The line has been opened for traffic as far as Liverpool, and for the present it is only intended to carry it to Goulburn, 125 m. from Sydney. Another railway has been opened connecting the chief towns in the valley of the Hunter with the port of Newcastle at the mouth of that river. There are several good roads in New South Wales, and the mails are carried over 1,023,265 m., though often over mere pathways, throughout the colony. There are 155 post offices, and the number of letters that passed through the general post office at Sydney in 1855 was 2,114,179, and of newspapers 2,100,989; the postal income was £24,902, and the expenditure £80,091. In 1855, 127,952 acres of public land were sold at an average of about £2 an acre. This land was divided into 5,910 lots, of which 3,462 were town allotments, 1,114 suburban, 1,244 country, and 90 special country. The present minimum price is fixed at £1 per acre. The effect of the present system is almost virtually to prevent laboring men and small capitalists from becoming land owners; but the growing dissatisfaction with it must soon cause its abrogation.—The colony of New South Wales possesses an excellent observatory, a university at Sydney, a Roman Catholic college, and numerous schools; a branch of the London mint, which issues Australian gold coin current in all the neighboring colonies, and in Mauritius, Ceylon, and Hong Kong; floral and horticultural and agricultural societies; a botanical garden containing most plants known in both tropical and temperate regions; hospitals and asylums, both benevolent and lunatic; and many public buildings, and works of great extent constructed chiefly by convict labor. The public press includes two daily newspapers and several other periodicals published at Sydney, and newspapers at Maitland, Bathurst, Goulburn, and other places. Sydney is the seat of the Australian metropolitan bishop. A new see was created in 1859 at Brisbane, capital of Queensland, on occasion of the separation of that colony from New South Wales. The government consists of a governor appointed by the crown, an executive council chosen by the governor, and two houses of legislature, one nominated by the governor and called the legislative council, and the other elected by the people and called the legislative assembly. No allowance is paid to any of these members, except to those of the ministry or executive council, which is composed of the colonial secretary, the treasurer, the solicitor-

general and attorney-general, and the minister of lands and public works. These ministers are all required to possess seats in the house of assembly, and retain their offices only so long as they can secure a majority in this branch of the legislature. The qualifications required for a voter are that he should be a householder, or if living in lodgings that he shall be earning wages at the rate of £100 a year, and that he should have resided 6 months in the colony. All voters are eligible to membership. The house of assembly, composed of 64 members, makes laws within the colony (which provisionally extend as far N. as Cape York) not repugnant to those of Great Britain; it regulates the whole of the revenue, and makes all appropriations for the public service. Measures passed by it do not become law till they have been approved by the legislative council and the governor, who has power to dissolve the house at pleasure. The revenue of New South Wales is derived from import duties and miscellaneous taxes, and from the proceeds of the sale of public lands and licenses to depasture. The revenue in 1858 was £1,422,466, an increase of £218,733 over 1857, and £321,301 over 1856, and including £240,538 from land sales, £160,989 from other branches of the land revenue, and £48,107 from the tax on gold. The expenditures of the mother country for the colony in 1857 were £59,646. Steam communication is maintained with England *via* Melbourne, Mauritius, and the Red sea, once a month; and the legislative assembly of the colony has appropriated £50,000 a year as a subsidy to be paid for a like service by the isthmus of Panama.—For information concerning the aborigines, the native animals, botany, geology, and history of New South Wales, see AUSTRALIA.

NEW STYLE. See CALENDAR.

NEW TESTAMENT. See BIBLE.

NEW YEAR'S DAY, the first day of the year, for many ages and in various parts of the world celebrated as a religious and social festival. With the post-biblical Jews the new year commenced and still commences with the autumnal month Tisri, the first day being celebrated by them with considerable ceremony. The Romans made an especial holiday of it, offering sacrifices to Janus, whose principal festival occurred on this day, and taking care that all they thought, said, and did should be pure and favorable, since every thing was ominous for the occurrences of the whole year. They appeared in the streets in festive garments, exchanged kindly salutations, and gave to each other presents called *strenæ*, consisting of gilt dates, figs, honey cakes, and copper coins having on one side the double head of Janus and on the other a ship. This custom of bestowing presents was made by some of the emperors an important source of their personal revenue, until modified by a decree of the emperor Claudius. The early Christian emperors however continued to receive them, notwithstanding they were condemned by the ecclesi-

astical councils on account of the pagan ceremonies at their presentation. Prynne in his "Histrio-Mastix," referring to the hostility of the early church to any imitation among Christians of the Roman saturnalia, says: "The whole Catholike church appointed a solemn publike faste upon this our new yeare's day, to bewail those heathenish enterludes, sports, and lewd idolatrous practices, which had been used on it; prohibiting all Christians, under pain of excommunication, from observing the calends or first of January (which wee now call new yeare's day) as holy, and from sending abroad new yeare's gifts upon it (a custome now too frequent), it being a mere relique of paganisme and idolatry, derived from the heathen Romans' feast of two-faced Janus, and a practice so execrable unto Christians, that not only the whole Catholike church, but even the four famous councils of (here follows a long array of authorities) have positively prohibited the solemnization of new yeare's day, and the sending abroad of new yeare's gifts, under an anathema and excommunication." The bestowal of gifts upon new year's day was not peculiar to the Romans. The druids distributed branches of the sacred mistletoe, out with peculiar ceremonies, as new year's gifts among the people; and the Saxons of the north, according to Bishop Stillingfleet, observed the festival with more than ordinary jollity and feasting, and by sending gifts to one another. In spite of the opposition of ecclesiastical councils, the practice continued through the middle ages; and among kings and their powerful vassals the interchange of presents was a distinguishing feature of the first day of the year. Henry III. of England is said to have extorted new year's gifts, and Queen Elizabeth's wardrobe and jewelry were probably almost wholly supplied from these annual contributions. It appears from the "Progresses and Processions" of her majesty, published by Nichols, that the lords spiritual and temporal of the realm, the chief officers of state, and the servants of the royal household down to the master cook, sergeant of the pastry, and dustman, were among the contributors to these largesses, which consisted of money, rich wearing apparel, plate, jewels, trinkets, sweetmeats, and an infinite variety of other things. Dr. Drake says that, although the queen made returns to the new year's gifts, in plate and other articles, she took care that the balance should be in her own favor. As late as 1692, as appears from the "Monthly Miscellany" for December of that year, the English nobility were accustomed, "every new year's tide," to "send to the king a purse with gold in it." Under the Tudors and Stuarts new year's gifts were given and received with mutual wishes of a happy new year among all conditions of people. An orange stuck with clover or a gilt nutmeg was a popular gift; tenants sent their landlords capons, and ladies received presents of gloves or pins, or in lieu

thereof, a composition in money, whence the terms "glove money" and "pin money." Brand in his "Popular Antiquities" enumerates many ceremonies and superstitious practices observed by the English and Scottish peasantry on the first day of the year, which, together with the once almost universal bestowal of gifts, have very much declined. In England the ringing in the new year from the belfries of churches is now the only open demonstration of joy at the recurrence of the anniversary. In Germany many ceremonies derived from old superstitions are in vogue; but throughout continental Europe, although the day is a universal holiday, congratulatory wishes have been generally substituted for the more substantial expressions of esteem formerly interchanged by friends. In Paris and other large cities almost incredible sums are still expended in bonbons and similar articles for presents. In the city of New York the day is made the occasion of social visits by gentlemen among the families of their acquaintance—a custom dating back almost to the settlement of the town by the Dutch, and which has been imitated with more or less success in other places in the United States.—For the religious festival of new year's day, see CIRCUMCISION, FEAST OF THE.

NEW YORK, one of the 13 original states of the American Union, and one of the middle states, situated between lat. 40° 29' 40" and 45° 0' 42" N., and long. 71° 51' and 79° 47' 25" W.; extreme length E. and W. 412 m.; breadth varying from 8 or 10 m. on Long island and 18½ m. at the W. extremity of the state, to 81½ m. from the Canada boundary to the S. point of Staten island; area, 50,519 sq. m., or 32,832,160 acres. It is bounded N. by Canada West (from which it is separated by Lakes Erie and Ontario and the river St. Lawrence), and by Canada East and Long Island sound; E. by Vermont (from which it is separated in part by Lake Champlain), Massachusetts, Connecticut, and the Atlantic ocean; S. by the Atlantic, New Jersey, and Pennsylvania; and W. by New Jersey, Pennsylvania, and Canada West. It is divided into 60 counties, viz.: Albany, Alleghany, Broome, Cattaraugus, Cayuga, Chautauqua, Chemung, Chenango, Clinton, Columbia, Cortland, Delaware, Dutchess, Erie, Essex, Franklin, Fulton, Genesee, Greene, Hamilton, Herkimer, Jefferson, Kings, Lewis, Livingston, Madison, Monroe, Montgomery, New York, Niagara, Oneida, Onondaga, Ontario, Orange, Orleans, Oswego, Otsego, Putnam, Queens, Rensselaer, Richmond, Rockland, St. Lawrence, Saratoga, Schenectady, Schoharie, Schuyler, Seneca, Steuben, Suffolk, Sullivan, Tioga, Tompkins, Ulster, Warren, Washington, Wayne, Westchester, Wyoming, and Yates. The cities, in the order of their population, are New York, Brooklyn, Buffalo, Albany (the capital), Rochester, Troy, Syracuse, Utica, Oswego, Poughkeepsie, Auburn, Schenectady, and Hudson. The state contains numerous large towns or villages, among the largest of which, in their order

of population, are Newburg, Lockport, Binghams, Elmira, West Troy, Yonkers, Ogdensburg, Rome, Cohoes, Rondout, Watertown, Saratoga Springs, Geneva, Ithaca, Dunkirk, Seneca Falls, Canandaigua, Lansingburg, Potsdam, Little Falls, Kingston, Corning, Peekskill, Flushing, Glen's Falls, Saugerties, Greenbush, Whitehall, Lyons, Astoria, Fulton, Waterford, Waterloo, Owego, Port Jervis, Tarrytown, and Niagara Falls. Each of these villages contains a population of from 8,000 to 10,000.—In population New York surpasses every other state in the Union. Under the colonial government, the number of inhabitants in 1698 was 18,067; 1703, 20,665; 1723, 40,564; 1781, 50,824; 1787, 60,437; 1746, 61,589; 1749, 78,848; 1756, 96,790; 1771, 163,837. The results of the U. S. decennial censuses have been as follows:

Census years.	Whites.	Free colored.	Slaves.	Total.
1790.....	814,143	4,654	21,324	840,120
1800.....	556,089	10,874	20,848	587,756
1810.....	918,690	25,888	15,017	959,049
1820.....	1,322,744	29,960	10,088	1,372,812
1830.....	1,873,663	44,870	73	1,918,608
1840.....	2,378,390	50,027	4	2,428,991
1850.....	3,048,225	49,069	3,097,294
1860.....	3,851,568

Censuses have also been taken by the state as follows: 1814 (total population), 1,085,910; 1825, 1,614,456; 1835, 2,174,517; 1845, 2,604,495; 1855, 3,466,212. Increase of population from 1698 to 1771, or during a colonial period of 73 years, 804.06 per cent., or at the rate of 11.014 per cent. per annum. Increase from 1790 to 1850, or during a period of 60 years, 810.67 per cent., or 13.51 per cent. per annum; 1840 to 1850, 27.52 per cent., or 2.75 per cent. per annum; 1850 to 1855, 11.91 per cent., or 2.38 per cent. per annum; and 1855 to 1860, 11.12 per cent., or 2.22 per cent. per annum. Of the total population in 1855, 1,727,650 were males and 1,738,562 females; of the whites, 1,706,278 males and 1,714,653 females; of the colored, 21,377 males and 23,909 females. Ages: under 5 years, 471,619; 5 and under 10, 394,881; 10 and under 15, 374,545; 15 and under 20, 358,942; 20 and under 25, 363,214; 25 and under 30, 325,077; 30 and under 35, 274,589; 35 and under 40, 214,898; 40 and under 45, 180,267; 45 and under 50, 183,392; 50 and under 60, 196,802; 60 and under 70, 108,040; 70 and under 80, 45,017; 80 and under 90, 12,258; 90 and under 100, 1,549; over 100, 91; unknown, 6,532. Natives of the United States, 2,528,444, of whom 2,222,221 were born in New York, and 35,923 in other states; of foreign countries, 922,896, of whom 50,608 were born in British America, 133,366 in Great Britain, 469,758 in Ireland, 226,546 in Germany, 18,366 in France, and 18,756 in other countries; unknown, 17,238. During the year ending June 1, 1855, the births were 102,522; deaths, 46,297; marriages, 21,551. By the same census, the occupations of 568,293 persons were returned, as follows: agriculture 318,980; commerce, trade, manu-

factures, mechanic arts, and mining, 312,697; labor not agricultural, 196,618; army, 1,462; sea and river navigation, 23,242; law, medicine, and divinity, 14,258; other pursuits requiring education, 11,104; government civil service, 4,985; domestic service, 6,324; other occupations, 3,628. Deaf and dumb, 1,422; blind, 1,186; insane, 2,742; idiotic, 1,812. Number of families, 663,124; freeholders, 361,013; dwellings, 522,325. Density of population, 68.61 to the square mile.—The outlines of the state are very irregular, only about one third of the entire boundaries consisting of right lines. Omitting Long island, the state somewhat resembles a congress boot, the heel being at New York city, and the toe at Chautauque county. If the Pennsylvania line were produced to the E. boundary, it would divide the state into two triangles. The river, lake, and ocean boundaries are all navigable waters, except 17½ m. on Poultney river, and consist of 852 m. on Lakes Erie, Ontario, and Champlain; 281½ m. on the St. Lawrence, Poultney, Hudson, Kill Van Kull, Delaware, and Niagara rivers; and 246 m. on Long Island sound and the Atlantic ocean. The boundaries along Canada, Vermont, Massachusetts, Connecticut, New Jersey, and Pennsylvania, all made up of right lines, form a total of 541.28 m. The principal islands belonging to the state are the following: in Niagara river, Grand, Squaw, Strawberry, Rattlesnake, Tonawanda, Beaver, Buckhorn, Cayuga, and Goat; in the St. Lawrence, Carlton, Grenadier, Fox, Wells, Grindstone, a large number of the Thousand islands, and Gallip; in Lake Champlain, Valcour, Crab, and Schuyler; in New York bay, the Atlantic ocean, and Long Island sound, New York, Staten, Long, Gardner's, Shelter, Plum, Fisher's, all the islands between Long island and Connecticut to within a few rods of the Connecticut shore, Sunken Meadow, Randall's, Ward's, Blackwell's, Governor's, Bedloe's, and Ellis. The last 8 are owned by the general government, and occupied as U. S. military posts. New York bay and harbor is sufficiently deep and capacious to accommodate all the shipping belonging to and trading with the port of New York. The other principal harbors are Dunkirk and Buffalo, on Lake Erie; Tonawanda and Lewiston on Niagara river; Genesee, Sodas, Oswego, Sackett's Harbor, and Cape Vincent on Lake Ontario; Ogdensburg on the St. Lawrence; Rouse's Point, Plattsburg, and Whitehall on Lake Champlain; and Sag Harbor at the E. end of Long island. The principal river of the state is the Hudson, which is navigable to Troy, 160 m. from its mouth. The St. Lawrence and Niagara on the N. and W. boundaries are also navigable. The Mohawk, the principal affluent of the Hudson, is a sluggish stream about 150 m. long, rising in the interior of the state and entering the Hudson at Waterford; it affords extensive water power at Little Falls and Cohoes. Its principal branches are West and East Canada creeks from the north, and Schoharie

creek from the south. Oswego river, which receives the waters of all the interior lakes, from Oneida and Cazenovia on the E. to Crooked and Canandaigua on the W., furnishes with its branches and tributaries, good water power at Penn Yan, on Crooked Lake outlet; at Waterloo, Seneca Falls, and Baldwinsville, on Seneca river; at Phelps, on Flint creek and Canandaigua outlet; at Auburn on Owasco outlet; almost the entire length of Skaneateles outlet (the fall being 453 feet in 9 m.); at Cazenovia and Chittenango, on Chittenango creek; and at Fulton and Oswego, on Oswego river. The Alleghany, Susquehanna, and Delaware, with numerous branches, drain the western, central, and eastern portions respectively of the S. part of the state, and furnish valuable and important water power at numerous points within the state. Cattaraugus and Tonawanda creeks are also considerable streams in the W. part of the state, the former furnishing important water power at numerous points, and the latter affording slack-water navigation for the Erie canal for about 10 m. from its mouth. The other principal streams are Buffalo creek, flowing into Lake Erie; Oak Orchard creek, Salmon and Black rivers, flowing into Lake Ontario; Oswegatchie, Grasse, and Racket rivers, tributaries of the St. Lawrence; Chazy, Saranac, and Au Sable rivers, and Wood creek, rapid streams or mountain torrents flowing into Lake Champlain, and furnishing almost unlimited water power; Susquehanna river, which rises in Otsego lake, and in its course in the state receives the waters of Charlotte, Unadilla, and Chenango rivers; and Chemung river, which drains a portion of the state between the Alleghany and Susquehanna, and receives the waters of Canisteo, Conchocton, and Tioga rivers. The principal branches of the Delaware are Popacton and Neversink rivers.—The state is noted for the great number of beautiful lakes in the interior and N. E. parts. The principal of these are Chautauqua and Cattaraugus, in the W.; Hemlock, Honeoye, Canadice, and Conesus in the Genesee basin, which discharge their waters into Genesee river; Crooked, Canandaigua, Seneca, Cayuga, Owasco, Skaneateles, Cross, Onondaga, Otisco, Cazenovia, and Oneida, in the central part of the state, all of which find an outlet for their waters through Oswego river; Otsego and Schuyler, which empty into the Susquehanna; and Schroon, George, Avalanche, Colden, Henderson, Sandford, Eckford, the Fulton lakes (8 in number), Racket, Forked, Newcomb, Long, Cranberry, Upper Saranac, Lower Saranac, Tupper's, Rich, Pleasant, and numerous other small lakes in the N. E. part. Canandaigua, Crooked, Seneca, Cayuga, Owasco, Onondaga, Skaneateles, Chautauqua, Otsego, and Oneida lakes, and Lake George, are all navigable for boats and steamers, and on many of them considerable trade is carried on. Lakes Erie, Ontario, and Champlain are navigable for vessels of all sizes. Seneca lake never freezes, and hence steamers

ply upon it throughout the year. The scenery of these lakes is world-renowned, and attracts thousands of pleasure seekers during the summer months.—The surface of the state is greatly diversified. Three distinct mountain ranges enter it from the S. and extend across it in a general N. E. direction. The most easterly of these ranges, a continuation of the Blue Ridge of Virginia, extends N. E. through Rockland, Orange, Putnam, and Dutchess counties, forming the highlands of the Hudson. The highest peaks of this range are Beacon hill, Dutchess co., 1,685 ft. high; Bull hill, Putnam co., 1,586 ft.; Butter hill, Orange co., 1,529 ft.; Old Beacon, Putnam co., 1,471 ft.; Crow Nest, Orange co., 1,418 ft.; Bear mount, Orange co., 1,350 ft.; Anthony's Nose, Putnam co., 1,228 ft.; and Breakneck, Orange co., 1,187 ft. high. The second range extends N. E. through Sullivan, Ulster, and Greene counties, terminating and culminating in the Catskill mountains on the Hudson. The highest peaks are Round Top, High Peak, and Pine Orchard, Greene co., respectively 3,804, 3,713, and 3,000 ft. high; and Rockland mount and Walnut hill, Sullivan co., 2,400 and 1,980 ft. high. The Shawangunk mountains, a high and continuous ridge between Sullivan and Orange counties, extending into the S. part of Ulster co., are the extreme E. spur of this range; and the Helderberg and Hellbark mountains are spurs extending N. from the main range into Albany and Schoharie counties. The third range extends N. E. through Broome, Delaware, Otsego, Schoharie, Montgomery, and Herkimer counties to the Mohawk, reappears on the N. side of that river, and extends N. E. to Lake Champlain, forming the mountain region in the N. E. part of the state known as the Adirondac mountain region. S. of the Mohawk this range assumes the form of broad, irregular hills; N. of that stream it is broken into several distinct spurs or ranges, all terminating upon Lake Champlain. (See ADIRONDAC MOUNTAINS.) Ranges of hills forming spurs of the Alleghanies occupy the S. part of the W. half of the state. The water-shed that separates the northern from the southern drainage of western New York extends in an irregular line through the southerly counties. That portion of the state S. of this water-shed, and embracing the greater part of the two southerly tiers of counties, is almost entirely a hilly country. The highest summits W. of the Susquehanna are in Alleghany and Cattaraugus counties, and are 2,000 to 3,000 feet above tide. N. of the water-shed the face of the country descends in a series of rolling and smooth terraces toward Lake Ontario, the region between the hills of the S. and the level lands of the N. being a beautiful, rolling country. S. of the highlands the surface is generally level or broken by low hills. The river system of the state consists of two general divisions, viz.: that part drained by the great lakes and the St. Lawrence, north-erly; and that part drained by the Hudson

and other rivers, southerly. The water-shed between these two divisions extends in an irregular line from Lake Erie eastward through the southern tier of counties to near the N. E. corner of Chemung co., thence N. E. to the Adirondac mountains in Essex co., thence S. E. to the E. extremity of Lake George, and thence nearly due E. to the E. line of the state. The northern of these divisions consists of 5 subdivisions or basins, viz.: the basin drained by Lake Erie, Niagara river, and Lake Ontario W. of Genesee river; the basin of Genesee river and its tributaries; the basin of Oswego river and its tributaries, and the small streams flowing into Lake Ontario between Genesee and Oswego rivers; the basin of the St. Lawrence and the streams flowing into Lake Ontario E. of Oswego river; and the basin drained by Lakes George and Champlain. The southern division consists of 4 subdivisions, viz.: the Alleghany basin, the Susquehanna basin, the Delaware basin, and the basin of the Hudson.—The state of New York presents a very complete series of the older rock formations, from the azoic up to the lower members of the carboniferous; but the groups of later age are not represented in the state, with few exceptions. The red sandstone of the middle secondary extends from N. E. New Jersey over Rockland co., terminating at the Palisades of trap on the W. side of Tappan bay. Some tertiary deposits of the pliocene period, which are of little extent, are found on the borders of the St. Lawrence river and Lake Champlain; and again the drift, or bowlder formation, overspreads the whole state, and is developed over Long island in beds of sand, gravel, and clays of such depth, that the rocky ledges are everywhere concealed from view except in a few points where the gneiss is laid bare on the shore of the East river opposite New York island. The great metamorphic belt of the eastern states passes into New York all along its eastern line, and to the N. of the Mohawk river it branches off over nearly all the rugged country which lies between Lake Ontario and Lake Champlain. In this district are the Adirondac mountains, which have already been described under their own name. The granitic and hypersthene rocks of which they consist spread almost to the St. Lawrence, from which the tract is separated by a belt of the Potsdam sandstone, which passes through the town of that name in St. Lawrence co., and encircles the great district of azoic rocks on its N. and W. sides; and next to this, bordering the St. Lawrence, the calciferous sandrock overlies the Potsdam sandstone. The birdseye, Black river, and Trenton limestones of the next upper group of rocks form a considerable portion of Jefferson co. on the E. end of Lake Ontario, and the strata extend along the S. W. border of the azoic district through the centre of Lewis co., following the S. W. side of the Black river to Norway in Herkimer co. The same calcareous rocks form the S. E. boundary of the azoic

tract, extending in a narrow belt from the S. W. to the N. E. corner of Saratoga co., and thence to Whitehall on the border of Vermont. The district of azoic rocks is also skirted along the W. shore of Lake Champlain by the same limestones, the broadest outspread of which is against the N. half of the lake, and the Potsdam sandstone also appears in several places on this side. The region thus encircled is the great iron ore district of northern New York. Beds of magnetic and specular ores are worked chiefly near Lake Champlain and in the S. W. part of St. Lawrence co.; and in the latter vicinity are the most promising lead mines E. of Wisconsin, though they are not now worked. The country lying E. of the Hudson river consists of the lower members of the New York system of rocks more or less metamorphosed, the sandstone passing into quartz rock, the blue stratified limestone into the crystalline and white marbles, and the argillaceous slates of the Hudson river group into silicious, talcose, and micaceous slates. These changes, most complete on the E. and S. E. side of the belt in Massachusetts and Connecticut, and along its continuation on the course of the highlands across S. E. New York, gradually disappear toward the Hudson in Columbia and Rensselaer cos. The unaltered silurian rocks cross the Hudson river in a belt reaching from the lower corner of Dutchess co. to Rondout in Ulster co., and extend into the N. E. portion of New Jersey. The metamorphic formations, consisting of the slates and gneiss with occasional beds of crystalline limestone or marble, occupy the counties of Putnam and Westchester, and the S. E. portion of Orange co. New York island consists of gneiss, and the same formation stretches across Staten island toward its reappearance near Trenton, N. J. The formation is split or rather covered along its S. E. half by the secondary red sandstone, which, commencing at Tappan bay, ranges through Rockland co. and across New Jersey into Pennsylvania. This group of altered rocks is the repository of valuable beds of hematite iron ore, numbers of which have been extensively worked near the line of Massachusetts and Connecticut. (See *HEMATITE*.) In the highlands are many beds of magnetic iron ore, as noticed in the article *IRON*. Numerous beds of white marble also are worked at several localities, for an account of which see *MARBLE*. It is in the Hudson river slates or lower silurian limestones that the mineral springs of Saratoga, Ballston, Sharon, and other places in this part of the country are found. As the rocks of the Appalachian system are traced from Pennsylvania and New Jersey, those of a later period than the Hudson river slates, instead of crossing the river on the general range of the outcrop toward the N. E., are deflected toward the N. W. before reaching the Mohawk river, the great development of azoic rocks in the northern part of the state seeming to split and turn aside these stratified formations.

This is the case with all that group of silurian rocks which make up the Shawangunk mountains, and pursue their course regularly with this ridge from the N. W. corner of New Jersey to the Hudson river at Rondout. The summit and W. slope of the mountains are covered with the hard silicious sandstone, called the Oneida conglomerate or Shawangunk grit, dipping toward the west, and overlying the Hudson river slates that occupy the central portion of the ridge. In the valley W. of the mountains are the limestones and shales of the Helderberg and Hamilton groups. These rocks as they approach the Hudson river, sweeping around to the W., traverse together the great length of the state and pass across the head of the Niagara river into Canada. The Oneida conglomerate appears again in Oswego co., running out to a point in Oneida co.; and between this and the long line of outcrop of the Helderberg and Hamilton groups on the S. are interposed the several intermediate formations. These are the Medina sandstone, stretching along the whole S. shore of Lake Ontario and part of Oneida lake to the N.; the Clinton group of red and variegated shales and sandstones, including in its E. and W. range the whole of Oneida lake, and reaching in a narrow belt from Schoharie co. across the Niagara river; the Niagara limestone and shale, the outcrop of which is on the S. side of the Clinton group from Oneida lake west; and lastly the Onondaga salt group, consisting of calcareous shales, gypseous marls, &c., extending from Sharon in Schoharie co. past Syracuse, and thence due W. across the Niagara river. In these formations the valuable mineral productions are the lead and copper ores of the Shawangunk grit (see LEAD), the fossiliferous iron ores of the Clinton group near Oneida lake, and the salt wells and gypsum beds of the Onondaga salt group.—Overlying the Hamilton group, the next formation on the W. and the S. is the series of sandstones, slates, and shales comprised in the Portage and Chemung groups. These overspread the whole southern portion of New York as far E. as the state of Pennsylvania extends, and toward the N. E. the formation reaches into Greene and Albany cos. Its northern line is along the N. portion of Wyoming co. and across the middle portions of Seneca and Cayuga lakes. In Delaware, Greene, Sullivan, and parts of Ulster and Broome cos., the red and gray sandstones of the Catskill group overspread the Portage and Chemung rocks; and upon some of the Catskills, and at a few localities in Delaware and Sullivan cos., the millstone grit or conglomerate, which forms the floor of the coal formation, caps the highest summits. Had these hills been 100 feet higher, they would have included one or more of the lower coal beds. (See CATSKILL MOUNTAINS.) This is the nearest approach in New York to the carboniferous formation. In Pennsylvania beds of coal are found within 6 m. of the line of the state; but

the gentle rising of the strata toward the N. brings the lower formations of the Portage and Chemung groups to the surface before reaching the state line. The Portage, underlying the shales of the Chemung, chiefly consists of thin-bedded sandstones of close grain and of gray and bluish colors. These are quarried in Ulster, Greene, Seneca, and Albany cos. for flagging stones, and are sent to New York to the amount of several million feet annually. They are shipped from Kingston, Saugerties, Coxsackie, Bristol, and New Baltimore. The formation also affords grindstones, which are quarried in different parts of its range. In the western part of the state the sandstones are sometimes of a bituminous character. At Rockville in Alleghany co., as stated by Prof. Hall, the clothes of the quarrymen even acquire the odor of bitumen, and the water of the springs, though clear, tastes of the same substance. At a number of places in Alleghany, Cattaraugus, and Chautauqua cos., springs of petroleum or rock oil issue from the rocks of this group, and jets of carburetted hydrogen gas sometimes accompany the oil, and are also seen bubbling up in the standing and running waters, especially of Cattaraugus co. A few miles above La Grange the gas is reported to be sufficient to maintain a constant flame. At Fredonia in Chautauqua co. the supply is so abundant that it has long been used for lighting the town. The lighthouse at Portland on Lake Erie is supplied with it, and near Forrestville it is also in sufficient quantity for economical application. The petroleum, which until recently has been deemed of little importance, is attracting much interest since the great developments of this useful oil in the neighboring region of Pennsylvania, and operations are already commenced for testing the capacity of the springs at Ouba in Alleghany co. and other points. (See PETROLEUM.)—The rock formations from the Potsdam sandstone up, which have been named, together with their various subdivisions, constitute what is called the New York system, and with the carboniferous group complete the Appalachian system. Though the whole series is found in Pennsylvania, the formations below the carboniferous are more fully developed in New York, and are especially richer in fossils. In this state therefore they have been studied to the best advantage, and when recognized in other parts of the country are generally known by the names given to them by the New York geologists. The series is presented in tabular form in the article GEOLOGY (vol. viii. p. 157). Except in the N. and E. portions of the state, the formations lie but slightly inclined from the horizontal; but the general dip being toward the S., lower formations constantly appear as one travels from Pennsylvania northward. Many of the groups are in great part made up of limestones, and even among the shales and slates of the others calcareous strata are of frequent occurrence. The effect of this wide distribution of calcareous matter has been to

insure a general fertility of soil, and to give to New York a high position among the agricultural states of the Union.—The soil and temperature of New York are well adapted to the successful cultivation of most of the crops and fruits of the temperate zone. Somewhat more than one half of the total area of the state is improved and under successful cultivation; 87 per cent. of the improved land is devoted to pasture, 25 per cent. to meadow lands, 37 per cent. to the raising of oats, Indian corn, wheat, buckwheat, rye, and barley, and 1 per cent. to the minor crops and gardens. In the northern counties and the highland regions along the S. border and upon the Hudson, stock and sheep raising and dairy farming are the almost exclusive agricultural pursuits; while the low lands that form the greater part of the surface of the W. portion of the state are best adapted to grain growing. Broom corn has long been the staple crop of the Mohawk valley intervals; tobacco is extensively raised in the Chemung valley, and parts of Onondaga and Wayne cos.; hops are a leading product of Madison, Oneida, Otsego, and Schoharie cos.; grapes are successfully cultivated in the valley of the Hudson below the highlands, on the N. shore of Long island, and in several of the lake valleys in the central part of the state. Maple sugar is an important product of the northern and central portions; and fruits, particularly apples, peaches, pears, and strawberries, are grown in the western counties N. of the water-shed. Large tracts in the vicinity of New York city are devoted to market gardens and to furnishing the city with milk. The climate, being modified and governed by the configuration of the surface, latitude, elevations above tide, character of soil, and geological formation, possesses a wider range than that of any other state in the Union. Those portions affected by the winds from the ocean, sound, and lakes are more even in temperature and suffer less severely from the late frosts of spring and the early frosts of autumn than any other portions of country in the same latitude not thus affected. The mean temperature of the state, as determined from observations made at 58 meteorological stations, for periods ranging from 1 to 25 years, is 46.49°. The mean length of the season of vegetation, from the first blooming of apples to the first killing frost, is 174 days; while on Long island it is 12½ days longer, and in St. Lawrence co. 22 days shorter. The mean annual fall of water in the forms of rain and snow is 40.93 inches.—The most noted waterfalls in the state are Niagara falls, in Niagara river, 2,900 ft. wide and 163 ft. high; Portage falls in Genesee river, consisting of 2 falls, of 70 ft. and 110 ft. and a series of rapids 150 ft.; Genesee falls in Genesee river, at and below Rochester, consisting of 3 falls, of 96 ft., 25 ft., and 84 ft., within a distance of 2½ m.; Trenton falls, in West Canada creek, Herkimer co., consisting of 5 cascades with a total fall of 200 ft. in ½ m.

Taghanic falls, Tompkins co., 230 ft.; Chittenango falls in Chittenango creek, Madison co., 186 ft.; Lyons falls, in Black river, Lewis co., flowing down an inclined plane 63 ft. at an angle of 60°; Kaaterskill falls, Greene co., consisting of 2 falls, 175 ft. and 85 ft.; Baker's falls, Washington co., consisting of a succession of falls and rapids, having a total descent of 76 ft. in 60 rods; Cohoes falls in the Mohawk, near its mouth, with a total fall including rapids of 108 ft.; Glen's falls, Warren co., 50 ft.; High falls, in the Hudson, Warren co., 60 ft.; High falls, Ulster co., 50 ft.; the Au Sable falls, in Wilmington, Essex co., 100 ft.; Enfield falls, Tompkins co., consisting of a series of cascades with a total fall of 230 ft.; Buttermilk falls, Genesee co., 90 ft.; and the falls in Fall creek, Tompkins co., consisting of 5 falls with a total descent of over 500 ft. in 1 m. In East Canada creek, about 2½ m. from its mouth, is a series of cascades and rapids, having a total fall of 75 ft. in 80 rods. Upon Stone Bridge creek, Warren co., is a natural bridge 40 ft. high, 80 ft. broad, and 247 ft. long. Dover Stone church, Dutchess co., is a ravine 25 ft. wide at the bottom, 1 to 3 ft. wide at the top, about 40 ft. long, and 40 to 50 ft. high. Near Kyserike, Ulster co., is a cave which has been explored ½ m. from its entrance. On Black river, at Lyon's falls, are the "Pictured Rocks;" and in Onondaga co. are the "Oratean Lakes" and "Green Lakes." The principal mineral and medicinal springs are the salt springs of Onondaga co., from which over 7,000,000 bushels of salt are annually manufactured; Saratoga Springs; New Lebanon and Stockport, Columbia co.; Massena, St. Lawrence co.; Richfield, Otsego co.; Avon, Livingston co.; Clifton, Ontario co.; Sharon, Schoharie co.; Chittenango, Madison co.; and Alabama, Genesee co. The Lake ridge, a slight elevation resembling an ancient shore or beach, extends from near Niagara river into Monroe co., at a distance of 4 to 8 m. from Lake Ontario. East of Genesee river this ridge is not continuous, but its line may be traced nearly the whole distance to the St. Lawrence near its point of egress from the lake. A second ridge, called "the Mountain ridge," a few miles S. of the Lake ridge, extends from Canada West across Niagara river, just above Lewiston, and nearly parallel to the shore of Lake Ontario into St. Lawrence co.; and down this ridge flow all the larger streams that empty into Lake Ontario. "Rock City," Alleghany co., upon a summit 1,400 ft. above the surrounding valleys, consists of a tract of 40 acres covered with rocks broken into regular layers forming streets and alleys. The most remarkable public works in the state are the Croton aqueduct, supplying the city of New York with water, 8 ft. 5½ in. high, 7 ft. 5 in. wide, and 40½ m. long, costing \$8,575,000; Niagara suspension bridge, 821 ft. long, 247 ft. above the water, and costing \$400,000; Portage bridge, on the Buffalo and New York city railroad, 800 ft. long, 234 ft.

above the bed of Genesee river, costing \$175,000, and the largest wooden structure of the kind in the world; Lewiston suspension bridge, 849 ft. long, 20 ft. wide, 60 ft. above the water, costing \$58,000; Cascade bridge over the Delaware, on the New York and Erie railroad, 250 ft. long, 190 ft. high, 24 ft. wide, consisting of a single arch, and costing \$70,000; the Niagara Falls hydraulic canal, $\frac{1}{2}$ m. long; the Lockport hydraulic canal, $\frac{1}{2}$ m. long; the locks in the Erie canal at Lockport and Cohoes; the aqueduct of the Erie canal across the Mohawk near Cohoes, 1,187 $\frac{1}{2}$ ft. long, 26 ft. high, and resting on 26 piers; and the Erie canal aqueduct across Genesee river at Rochester.—The agricultural products of the state, according to the census of 1855, were as follows: 3,256,941 tons of hay, 194,846 bushels of grass seed, 9,092,402 of wheat, 27,015,296 of oats, 3,039,438 of rye, 3,563,540 of barley, 2,481,079 of buckwheat, 19,390,692 of Indian corn, 15,191,852 of potatoes, 705,963 of peas, 244,079 of beans, 985,528 of turnips, 478,277 of carrots, 15,027 of onions, 16,662 of clover seed, 37,094 of flax seed, 4,907,556 lbs. of flax, 7,192,254 of hops, 246,508 of tobacco, 12,668,831 bushels of apples, 273,682 bbls. of cider, 4,935,816 lbs. of

maple sugar, 85,092 galls. of maple molasses, 18,182 galls. of wine, 2,557,876 lbs. of honey, 138,084 of wax, 90,298,074 of butter, 38,944,250 of cheese, 20,965,861 galls. of milk sold, 9,231,959 lbs. of wool, 1,510 tons of broom corn, 1,611 bushels of grapes, 115,411 of peaches, 34,492 of dried fruit, and 65,677 of other fruits, including pears, cherries, currants, plums, berries, &c. The products of the market gardens were sold for \$1,133,632, garden seeds for \$40,889, fruit and ornamental trees for \$142,328, eggs for \$1,360,673, and miscellaneous agricultural products for \$1,421,750. According to the same census, the live stock consisted of 579,715 horses, 2,254 mules, 2,105,465 neat cattle, 1,068,427 cows, 1,069,792 swine, and 2,217,024 sheep, and the poultry sold amounted to \$1,076,598.—The manufacturing interests of the state are very extensive, and in many sections they surpass those of agriculture or commerce. Since the completion of the lines of internal improvements, manufactures have received more attention, and now flourishing establishments are to be found in almost every part of the state. The following table exhibits the statistics of the most important manufactures, according to the state census of 1855:

Manufactures.	Number of establishments.	Persons employed.	Capital.		Cash value of	
			Stock and real estate.	Tools and machinery.	Materials.	Manufactured products.
Agricultural tools and implements.....	302	2,674	85	\$844,355	\$1,205,929	\$3,120,429
Metallurgy.....	4,733	22,846	85	6,426,373	21,804,533	42,192,897
Fibrous and textile substances.....	699	19,689	89	5,406,825	10,304,173	19,642,035
Chemical processes, manufactures, and compounds.....	1,351	14,846	74	7,561,202	20,692,784	61,037,022
Lamps, lanterns, grates, and stoves.....	37	1,373	90	201,908	949,185	2,343,221
Steam engines, boilers, locomotives, &c.....	22	4,343	90	1,312,650	2,374,767	4,231,204
Navigation and maritime implements.....	296	4,736	90	261,245	2,992,722	2,263,106
Mathematical, philosophical, and optical instruments.....	49	267	90	125,449	159,000	257,019
Civil engineering and architecture.....	554	5,317	90	442,511	1,057,808	2,664,200
All kinds of wheel carriages, railroad cars, &c.....	1,423	5,222	92	619,154	2,610,609	6,977,265
Pumps, fire engines, and bellows.....	44	611	90	79,495	261,603	691,695
Lever, screws, scales, and other mechanical powers.....	19	79	90	12,100	47,121	122,700
Grinding mills, mill gearing, &c.....	1,516	2,694	90	2,172,222	42,254,543	69,195,426
Lumber, and tools and machines for its manufacture.....	6,794	21,514	2,263,174	2,004,875	12,264,267	24,202,941
Stone, clay, pottery, and glass manufactures.....	365	12,212	2,895,690	1,122,654	2,248,209	2,694,217
Leather and leather goods.....	2,015	19,242	4,429,122	956,917	14,931,705	27,276,168
Household furniture and domestic implements and machines.....	239	2,379	1,277,279	252,294	2,725,257	2,165,243
In the polite, fine, and ornamental arts.....	222	4,222	2,422,717	2,005,209	2,271,735	2,221,161
Firearms, implements of war, powder and shot.....	76	222	172,145	140,640	569,754	222,065
Surgical, medical, and dental instruments, &c.....	24	211	111,250	19,000	73,549	225,822
Wearing apparel and toilet articles not chemical.....	1,010	22,124	2,504,673	721,649	12,656,115	22,042,220
Miscellaneous manufactures.....	497	4,190	1,722,673	1,112,581	5,209,249	8,200,624
Total.....	24,822	214,899	71,120,407	25,212,576	617,294,229	9517,422,221

—The position of New York gives it peculiar facilities for maritime affairs, and through its ports a large proportion of the commerce of the nation is carried on. The federal government has established 11 districts within the state for the collection of revenues, and the principal offices in these districts are located severally at Sag Harbor, New York, Plattsburg, Ogdensburg, Cape Vincent, Sackett's Harbor, Oswego, Rochester, Lewiston, Buffalo, and Dunkirk. The total amount of customs collected at all the ports of entry in the United States for the year 1857 was \$63,875,905.05, of which sum \$49,510,753.79 was collected at the offices in this state. The total tonnage of the United States for the year ending June 30,

1859, was 5,145,087 tons, of which amount 1,629,451 tons belonged to the ports of New York. The movement of shipping in the state in that year was as follows:

Flags.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
American.....	5,657	2,207,726	4,726	2,254,124
Foreign.....	4,999	1,905,279	4,577	1,274,766
Total.....	10,656	4,212,005	9,303	3,528,890

Value of imports, \$229,181,849, of which \$133,216,984 was in American vessels; value of exports, \$104,726,546, of which \$59,295,645 was in American vessels. In the same year, 107 vessels were built in the state, with an aggre-

gate burden of 16,314 tons. The statistics of the Canada trade for the year ending June 30, 1858, present the following results: value of imports from the Canadas, duty free, into the United States, \$14,752,255; into New York state, \$7,918,092; value of exports to the Canadas paying duties, from the United States, \$23,651,727; from New York, \$15,806,519. Vessels entered from Canadian ports in 1858: American 2,566, foreign 3,280, total 5,846; cleared: American 2,564, foreign 3,549, total 6,113. Tonnage entered: American 1,186,582, foreign 703,898, total 1,890,480; cleared: American 1,124,041, foreign 698,768, total 1,822,809.—The fisheries of the state are quite subordinate to the other branches of industry. On June 30, 1859, only 8,758 tons of shipping belonging to this state were employed in the whale fisheries, while the total of whaling vessels in the United States at the same date was 185,728 tons. Large numbers of fishermen obtain a livelihood from the fisheries on the shores and in the bays of Long island; while about \$100,000 worth of shad are annually taken in the Hudson below the highlands, and \$30,000 worth of sturgeon from the same river are annually sold in the Albany markets. There are also extensive fisheries on the great lakes, especially near the E. end of Lake Ontario; and in Ohamont bay 10,000 bbls. of herring and whitefish have been taken in a single season.—The following table exhibits the extent and cost of the railroads lying wholly or partly in the state on Oct. 1, 1859:

Railroad corporations.	Length of road laid in miles.	Cost of roads and equipments.
Albany, Vermont, and Canada..	88.00	
Albany and West Stockbridge..	28.00	\$2,292,924 23
Black River and Utica.....	84.94	1,237,553 57
Bloomburg and Corning.....	14.81	498,661 28
Buffalo, New York, and Erie....	142.00	3,150,723 14
Buffalo and State Line.....	68.84	2,779,994 06
Cayuga and Susquehanna.....	84.61	
Chemung.....	17.86	400,000 00
Elmira, Jefferson, and Canandaigua..	46.84	
Genesee Valley.....	15.50	393,234 93
Hudson and Boston.....	17.38	175,000 00
Hudson River.....	144.00	11,838,279 64
Long Island.....	99.00	2,566,270 07
New York Central.....	555.88	80,840,718 71

Sackett's Harbor and Ellisburg..	18.00	
Saratoga and Schenectady.....	31.00	480,634 15
Saratoga and Whitehall.....	40.86	908,590 92
State Island (opened in 1850)..	114,014 67
Syracuse, Binghamton, and New York..	81.00	2,851,293 80
Troy and Bennington.....	5.33	268,913 57
Troy and Boston.....	84.91	1,510,518 63
Troy and Greenbush.....	6.00	294,781 43
Troy Union.....	3.14	732,114 73
Watertown and Rome.....	94.76	2,159,503 04
Williamsport and Elmira.....	8.00
Total.....	2,622.10	\$122,761,531 07

There are in addition 49.65 m. of horse railroad in the cities of New York and Brooklyn, costing \$5,671,528.74. The capital stock of the above named roads was \$39,063,200; paid in capital, \$72,900,911.79; funded and floating debt, \$73,118,567.42; number of passengers carried during the year ending Oct. 1, 1859, 51,386,998; number of miles travelled by passengers, 370,989,486; tons of freight carried, 3,859,283; cost of operating roads, \$6,669,165.31; total earnings, \$20,841,877.62; interest paid, \$3,824,938.97; net income, \$3,625,269.70; amount of dividends, \$2,586,718. There were also 508.42 m. of railroad in progress of construction at the same date. The following table exhibits the extent of the state canals in operation, and the tolls received from the same, for the year ending Sept. 30, 1859:

Canals.	Length in miles.	Tolls.
Erie canal.....	350.58	\$1,549,305 86
Champlain canal and Glen's Falls feeder.....	78.00	106,654 79
Black River canal and improvement	90.60	5,963 02
Chenango canal.....	97.00	17,301 73
Oneida Lake canal.....	6.00	701 41
Oswego canal.....	38.00	69,333 37
Baldwinsville canal.....	1.00	26 08
Oneida River improvement.....	20.00	2,044 84
Seneca River towing path.....	5.00	133 89
Cayuga and Seneca canal.....	22.77	17,449 54
Crooked Lake canal.....	8.00	705 06
Chemung canal and feeder.....	39.00	16,863 66
Cayuga inlet.....	3.00	173 26
Genesee Valley canal and Danville side cut.....	118.00	23,163 93
Extension of Genesee Valley canal.	6.70
Navigable feeders not above named.	3.25
Total.....	886.95	\$1,512,310 80

The Delaware and Hudson canal, the property of an incorporated company, is 109 m. long (88 m. being in this state); the present capital of the company is \$7,500,000; the tolls in 1857 amounted to \$485,198.44.—The business of banking, as now pursued under the banking laws of this state, in utility and safety, is probably superior to the banking system of any other state in the Union. On Jan. 1, 1860, there were 300 banks of issue, whose condition was as follows: Liabilities: capital, \$110,997,040; circulation, \$37,780,266; deposits, \$107,772,208; profits on hand, \$11,888,946. Resources: notes, bills of exchange, &c., \$237,264,819; specie, \$22,026,137; real estate, \$8,647,503; total, \$267,988,459.—On Jan. 1, 1860, there were 97 joint stock fire insurance companies, with a capital paid in of \$20,007,000; total assets, \$26,823,884.21; liabilities, \$2,144,553; amount received in cash premiums, \$6,421,842.54; losses paid during the year, \$2,681,986.08; dividends paid, \$2,851,722.74; outstanding risks, \$719,267,809.62. There were 82 mutual fire insurance companies, with a cash capital of \$4,798,506.17; premium notes, \$4,591,181.99; other assets, \$527,852.16; liabilities, \$95,066.43; cash premiums paid during the year, \$194,403.11; losses paid, \$94,501.71; outstanding risks, \$37,810,910.92. There were 14 marine insurance companies, whose total

assets amounted to \$20,932,067.80; premiums earned, \$12,939,201.68; losses and expenditures, \$9,446,298.09. There were 23 fire and marine insurance companies of other states transacting business in this state; the total capital of these companies was \$14,065,219; total assets, \$26,161,079.65; cash premiums received in this state, \$1,860,512.75; dividends paid, \$1,880,268; outstanding risks, \$779,801,816.87. The life insurance companies, 8 in number, report a capital and accumulations of \$12,090,815.24; cash premiums received, \$1,801,184.82; premium notes received, \$212,242.02; outstanding risks for life, \$68,203,270; for shorter terms, \$3,944,166.32. There were 7 life insurance companies of other states transacting business in this state; these companies reported a capital and accumulations of \$8,906,999.27; cash premiums received, \$1,398,263.74; premium notes received, \$558,484.38; outstanding risks for life, \$65,950,851.50; for shorter terms, \$3,849,690. There were also 6 foreign life insurance companies transacting business in the state; these companies had \$594,000 on deposit in trust in the state insurance department.—According to the state census of 1855, there were 5,077 places of worship, of which 882 were Baptist, 85 Christian, 801 Congregational, 16 Disciples', 4 Evangelical, 100 Evangelical Lutheran, 134 Friends', 11 German Evangelical Reformed, 19 Jewish synagogues, 6 Mennonite, 1,580 Methodist, 4 Moravian, 3 New Jerusalem, 710 Presbyterian, 346 Protestant Episcopal, 1 Communion of True Inspiration, 8 Protestant (miscellaneous), 260 Reformed Dutch, 291 Roman Catholic, 8 Second Advent, 3 Shakers', 7 True Dutch, 152 union, Bethel, and free, 16 Unitarian, and 133 Universalist. The total value of churches and lots was \$27,769,828; of other real estate, \$3,710,816. The salaries of the clergy amounted to \$2,411,683.—According to the annual report of the superintendent of public instruction for the year ending Sept. 30, 1859, the number of public schools in the state was 11,621, of which number 827 were free schools, and the remainder were supported by income from the common school fund, state and county taxes, and district rate bills; number of school houses, 11,576; number of children between 4 and 21 years of age, 1,272,486; number of pupils in the public schools, 851,588; teachers employed, males 8,515, females 17,896; teachers employed 6 months or over, 14,659; average length of school during the year in the rural districts, 7½ months; average salaries of teachers in city schools, \$385.48 per annum; in the rural districts, \$15.93 per month (over ¾ of all the teachers employed were females, and in the rural districts the compensation often included board); volumes in the school district libraries, 1,271,279; total cost of support of schools, \$3,664,617.57. The school money apportioned for the year 1860 was derived from the following sources: from common school fund, \$155,000; from U. S. deposit fund, \$165,000; from

state school tax, \$1,058,878.04. The number of private schools was 1,520, and the estimated number of pupils attending the same was 50,000. The number of academies subject to the visitation of the board of regents of the university in 1859 was 208, from 185 of which reports were received. According to these reports, 993 teachers (481 males and 512 females) were employed; the total number of pupils in attendance during the previous year was 36,783, of which number 21,301 pursued classical studies 4 months or more. The value of buildings, lots, libraries, apparatus, and endowments was \$2,694,695; and the total indebtedness of all the institutions was \$279,168. The income from personal property and real estate was \$31,044; from tuition fees, \$337,771; from the literature fund, \$39,869; from regents of the university for the education of common school teachers, \$15,738; from other sources, \$153,990; total annual revenue, \$578,412; paid salaries of teachers, \$410,614; total annual expenditures, \$558,318; number of volumes in libraries, 99,940. The regents of the university have made provisions for the education of teachers, by making an annual appropriation to certain academies to defray the expense of instructing a teachers' class at least 4 months or one term in each year. In 1859 teachers' classes were formed in 90 academies, and 1,804 teachers (711 males and 1,093 females) received instruction. The state normal school, situated at Albany, was established in 1844; to Sept. 1859, it had furnished tuition, for a longer or shorter period, to 3,288 pupils, of which number 1,120 (502 males and 618 females) had been graduated from the institution; the number of pupils for the scholastic year 1858-'9 was 312 (103 males and 209 females); number of graduates, 68 (21 males and 42 females); number of professors and teachers, 10. An experimental school is connected with the institution. In 1859 teachers' institutes were held in 50 counties, at which 6,766 teachers received instruction at an expense to the state of \$4,981.38. The state contains 14 colleges, viz.: Columbia, at New York; Union, at Schenectady; Hamilton, at Clinton; Hobart, at Geneva; university of the city of New York; Madison university, at Hamilton; St. John's, at Fordham; university of Rochester; Troy university; Genesee college at Lima; Elmira female college; Ingham university, at Le Roy; New York state agricultural college, at Ovid; and People's college, at Havana. The last two are not yet fully in operation. The aggregate number of professors and tutors in the first 10 of these institutions (all that reported) for the scholastic year 1858-'9 was 127; number of students, 1,550; graduates, 280; volumes in libraries, 110,495; total value of buildings, lots, libraries, and apparatus, \$897,989. There are 7 medical colleges in the state, viz.: college of physicians and surgeons, New York; medical department of the university of the city of New York; New York medical college; metropolitan medical college;

Albany medical college; Geneva medical college; and medical department of the university of Buffalo. Total number of professors for the year 1859, 67; students, 868; graduates, 265. The same year the state contained 10 theological seminaries, as follows: general theological seminary of the Protestant Episcopal church, New York; theological department of Hartwick seminary; theological department of Martin Luther college, Buffalo; Rochester theological seminary; St. Joseph's theological seminary, Fordham (discontinued in 1860); theological department of St. Lawrence university, Canton; theological department of Madison university, Hamilton; Auburn theological seminary; theological seminary of Associate Reformed church, Newburg; and union theological seminary, New York. Number of professors, 80; students, about 300.—The state of New York contains a large number of charitable institutions. The institution for the deaf and dumb in New York city, in 1859, reported 808 pupils, of whom 220 were supported by the state at an expense of \$150 each per annum. The New York institution for the blind reported for the year ending Oct. 1, 1859, 175 pupils appointed by the state; total number of pupils about 200. The state lunatic asylum at Utica was opened in 1843, and to Jan. 1, 1859 (a period of 16 years), 5,516

patients had been treated, of whom 4,896 had been discharged, 2,226 had recovered, 801 were improved, 1,194 unimproved, 686 had died, and 89 were not insane. The number treated in 1858 was 787; average number annually for 16 years, 881. The New York state asylum for idiots at Syracuse has been in successful operation as a state institution for 6 years; average number of pupils annually, over 100; number in 1860, 140; cost of building, \$75,000. The buildings for the state inebriate asylum at Binghamton are being erected. During the year 1858, 103,499 county and 22,205 town paupers were relieved or supported, of whom 18,422 (6,219 males and 7,203 females) were in poorhouses. Of the whole number relieved, 65,212 were foreigners, 4,246 were lunatics, 1,082 idiots, and 88 mutes. The total expenses for support of the poor were \$1,491,891.28. The house of refuge at Randall's island during the year 1860 received about 1,000 children, of whom 550 (445 boys and 105 girls) remained at the close of the year. The western house of refuge at Rochester received 186 boys, discharged 145, 5 escaped, 3 died, and 409 remained; total number of inmates during the year, 562. There are state prisons at Sing Sing, Auburn, and Dannemora, Clinton co. The reports from these for the year 1860 show the following statistics:

	Sing Sing.	Auburn.	Clinton.	Total.
Number of convicts, Sept. 30, 1859.....	1,223	811	447	2,481
Received during year ending Sept. 30, 1860.....	457	239	114	809
Discharged, died, pardoned, and escaped.....	340	241	180	761
In prison, Sept. 30, 1860.....	1,375	809	481	2,665
Earnings.....	\$111,640 92	\$100,245 73	\$26,640 92	\$238,527 56
Expenses.....	188,185 36	81,817 60	63,252 61	252,705 57

On Sept. 30, 1860, the Sing Sing prison contained 137 female convicts. The Auburn prison contains an asylum for insane convicts, opened in Feb. 1859, from which date to Sept. 30, 1860, 69 convicts had been received, and 14 discharged. The state also contains 5 penitentiaries or workhouses, in Albany, Buffalo, Kings co. (near the south line of Brooklyn), New York (on Blackwell's island), and Onondaga co. (at Syracuse).—In 1855 the newspapers and the periodicals published in the state were as follows: 73 daily, 13 tri-weekly, 16 semi-weekly, 411 weekly, 18 semi-monthly, 113 monthly, 16 quarterly, 2 semi-annual, and 16 annual; total newspapers, 559; other periodicals, 112. For the year 1859 the organized militia was composed of 8 divisions, 26 brigades, 64 regiments, and in the aggregate 18,846 men.—The legislative department consists of a senate and assembly, the former composed of 32 members chosen by single districts every 2 years, the whole number being chosen at once, and the latter of 128 members elected annually by single districts; pay of members of the legislature, \$3 a day for not more than 100 days, and mileage. The executive department consists of a governor elected for 2 years, salary \$4,000 and house rent; a lieutenant-governor, elected for the same time, salary during the session of the legislature \$6 a day and mileage;

secretary of state, comptroller, treasurer, state engineer and surveyor, each \$2,500 a year, and attorney-general, \$3,000 a year, all elected by the people. The chief officers of the administrative department are a superintendent of public instruction, \$2,500; 19 regents of the university, without salary; superintendent of the banking department, \$5,000; superintendent of the insurance department; 3 inspectors of state prisons, each \$1,600; 3 canal commissioners, each \$2,000; auditor of canal department, \$2,500; 3 canal appraisers, each \$2,000; superintendent of weights and measures, \$500; and 3 state assessors. The officers of the judiciary department are 8 judges of the court of appeals, and 33 justices of the supreme court, salary \$3,500 each per annum; clerk of the court of appeals and state reporter, each \$2,000. The state is divided into 2 federal judicial districts, in each of which is held a district court. The officers of this court in each district are a district judge, attorney, marshal, and clerk. These courts have nearly concurrent original jurisdiction in all matters in which the United States is a party, and in offences against the federal laws. An appeal lies from the district to the circuit court, and from thence to the U. S. supreme court. The state courts consist of a court for the trial of impeachments, the court of appeals, the su-

preme court, and the court of oyer and terminer. The court for the trial of impeachments is composed of the senate and the judges of the court of appeals; it is a court of record. The court of appeals is composed of 8 judges, 6 of whom constitute a quorum; it has power to correct and reverse all proceedings of the supreme court. The supreme court has general jurisdiction in law and equity, and power to review the judgments of the county courts. The county courts are held by the county judge, assisted by 2 justices of the peace elected annually for the purpose. The judge also performs the duties of surrogate; but in counties having a population of over 40,000, the legislature may provide for the election of a surrogate. County courts have jurisdiction in civil cases where the amount in dispute is not above \$2,000; in actions for damages for injury to the person or trespass upon property not exceeding \$500; in replevin suits of property not valued above \$1,000; for foreclosure of mortgages, sale of real estate of infants, partition of lands, admeasurement of dower, satisfaction of judgments over \$75, and the care and custody of lunatics and habitual drunkards. Surrogates' courts have the ordinary jurisdiction of courts of probate. Justices' courts have jurisdiction in civil suits where the amount in dispute does not exceed \$100 in value; in criminal cases for imposing fines not exceeding \$50, and of imprisonment in the county gaol not exceeding 6 months. The judges and justices are all elected by the people.—At the advent of the whites the S. E. part of New York was inhabited by several subordinate tribes of Indians belonging to the Algonquin race, and the remaining part of the state by the celebrated Five Nations of Iroquois stock. The names of places bequeathed by the various tribes indicate to what race they belonged; the Algonquin words being harsh and full of gutturals, while the Iroquois names are usually smooth, soft, and musical. The Five Nations included the Mohawks upon the lower Mohawk river, the Oneidas to the S. E. of Oneida lake, the Onondagas to the S. of Onondaga lake, the Cayugas on the E. bank of Cayuga lake, and the Senecas W. of Seneca lake. Iroquois war parties carried their conquests in all directions, and fought fierce battles with native tribes in the wilds of Canada, upon the prairies of the West, in the swamps of Carolina and the everglades of Florida. In 1712 the Tuscaroras, an offshoot of the Iroquois stock, after a defeat by the English settlers of Virginia, came north, settled upon the Susquehanna near the S. boundary of the state, and became incorporated in the Iroquois league; and the Indians who were bound by this compact were afterward known as the Six Nations. Samuel Champlain, the French navigator, was the first white man that ever set foot upon the soil of New York. On July 4, 1609, with two white attendants and a company of Canadian Indians, he entered the lake which bears his name, and

on the 80th fought a battle on the W. shore with a band of Mohawks, and defeated them. By this act of Champlain the French incurred the hatred of the Five Nations, and hostilities between them never entirely ceased until the final overthrow of the French power in America. On Sept. 9, 1609, Henry Hudson, the English navigator in the employ of the Dutch East India company, with his little shallop Half-Moon of 80 tons, discovered the bay of New York. Three days later he entered the river which bears his name, and continued his voyage to some point between the present cities of Hudson and Albany. The land discovered by Hudson was claimed by Holland and named New Netherlands. In 1611 the states-general granted special privileges to any company which should open a trade with the natives of this region. During the next 10 years many trading voyages were made, the country was explored along the Hudson and around Long Island sound, and small trading posts were erected at Fort Orange (now Albany), and on Manhattan island. In 1621 the Dutch West India company was incorporated, and under its auspices two years afterward 18 families settled at Fort Orange, and 80 families at New Amsterdam. In 1626 Peter Minuit, the director-general, purchased Manhattan island of the natives for the value of \$24. In 1629 the company passed an act enabling all who wished to obtain manorial possessions in the country. By this act the most valuable part of the company's land soon passed into the hands of individuals, and an aristocratic element was introduced. The effort to establish feudal privileges failed; but the land monopolies granted at this time led, more than two centuries afterward, to serious disturbances known as the "anti-rent difficulties." Wouter van Twiller, the successor of Minuit, appointed in 1638, was succeeded in 1638 by William Kieft. During the administration of the latter, some troubles having arisen with the natives, an attack was suddenly made by the whites upon the nearest Indian villages, and more than 100 unoffending men, women, and children were massacred. A bloody war ensued, which seriously endangered the existence of the colony. In 1647 Kieft was succeeded by Peter Stuyvesant, who immediately inaugurated a new order of things. The Indians were conciliated, and the general affairs of the colony were more systematically administered. The Dutch settlements, spreading to the east and west, came in collision with the English upon the Connecticut, and with the Swedes upon the Delaware. In 1655 Stuyvesant took forcible possession of the Swedish territory and annexed it to New Netherlands. The border contests with the English on the east continued as long as the Dutch held possession of the country. The English claimed New Netherlands as part of Virginia, a claim founded upon the prior discovery of Cabot. In 1622 the English minister at the Hague demanded that the enterprise of planting a Dutch colony upon the Hudson

should be abandoned. In 1627 Gov. Bradford of Plymouth gave notice to Peter Minnits that the patent of New England extended to lat. 40°, and that the Dutch had no right "to plant and trade" north of that line. On March 12, 1664, Charles II. granted a charter of all the lands lying between the Hudson and Delaware to his brother the duke of York. This included New Netherlands and a portion of the territory which had been previously granted to Connecticut, Massachusetts, and New Hampshire. In August of the same year, without any declaration of war, Col. Nicolls at the head of an English force appeared before New Amsterdam, and demanded its surrender. Being in no condition to resist, Gov. Stuyvesant complied with the demand, and the whole country quietly passed into the hands of the English. New Amsterdam was named New York, and Fort Orange Albany, and the name of New York was also applied to the whole province. New York was subsequently recaptured by the Dutch, but was soon after restored to the English. The Dutch engaged in the slave trade as early as 1627, and at the surrender in 1664 the colony contained more slaves in proportion to its inhabitants than Virginia. Owing to the preponderance of the aristocratic element, but little attention was paid to general education, or to any measures calculated to elevate the people. Political freedom and religious toleration made advances in spite of the rulers, and along the Hudson grew up a sturdy and industrious yeomanry. The English rule, under the duke of York, gave little encouragement to freedom. Large estates and special privileges were granted to favorites, heavy taxes were imposed, and onerous restrictions were placed upon manufactures and trade. When the duke of York ascended the throne as James II., the government became an appendage of the crown, but was otherwise unchanged. The accession of William and Mary to the throne of England in 1689 was hailed by the people of this colony as a harbinger of better times; but the Protestant William was found no more willing to concede popular rights and forego ancient privileges than the Catholic James. The royal governors had frequent collisions with the representatives of the people concerning the right of taxation and other matters of similar character. Democratic principles continued to spread, and the controversies that took place from time to time gradually prepared the people for the great final struggle that severed the colonies from the mother country. In 1689 the people revolted from the tyranny of Nicholson, the governor under James II., and, under the lead of Jacob Leisler, a merchant of New York, seized the government and administered it in the name of William and Mary. Although never officially recognized as governor, Leisler continued at the head of affairs more than two years, when he was superseded by Gov. Sloughter, bearing a commission direct from the English sover-

eigns. Offering some slight resistance to Sloughter upon his arrival, Leisler and his son-in-law Milborne were arrested, tried for treason, and executed. From the earliest period of the settlement the French were engaged in almost incessant warfare with the Five Nations. Sometimes, by the distribution of valuable presents and by the exertions of the missionaries, they would succeed in effecting a treaty with their enemies, but the natives would generally recommence hostilities on the slightest provocation. On some occasions the Indians were induced to remain neutral in the wars between the French and English, but usually they completely protected the frontier settlements from French incursions on the north and west. In 1684 Gov. Dongan concluded an offensive and defensive treaty with the Indians, and from that time the English became the recipients of that friendship which had been before bestowed upon the Dutch. In 1687 the Seneca country in western New York was invaded by a French army under De Nonville, governor of Canada; and in 1689 the Five Nations retaliated by invading Canada. In this last expedition more than 1,000 French settlers were slain, and the whole French province was threatened with destruction. On the night of Feb. 9, 1689, a party of French and Canadian Indians fell upon Schenectady, destroyed the place, and massacred nearly all the inhabitants. In 1693 a French expedition against the Mohawks succeeded in taking one of the Indian forts and in capturing 800 prisoners, but the greater part of the invaders perished with cold before reaching Canada. The peace of Ryswick in 1697 concluded the hostilities between England and France, and Count Frontenac, then governor of Canada, turned his whole force against the Five Nations. His plans however were frustrated by the earl of Bellamont, then royal governor of New York, who declared he would make common cause with the Indians in case any attack was made upon them. During the continuance of Queen Anne's war, from 1702 to 1713, hostilities in New York were confined to skirmishes upon the frontiers, and in the preparation for expeditions which failed from want of promised aid from England, but which cost immense sums of money and involved the colony largely in debt. In 1731 the French built the important fortress of Fort Frederic at Crown Point on Lake Champlain, completely commanding the natural pass between the Hudson and St. Lawrence. During King George's war, which commenced in 1745 and continued 8 years, frequent skirmishes occurred upon the disputed territory between the advanced English posts on the Hudson and the French fortress at Crown Point; but no general engagement took place within the limits of the state. The great final conflict between England and France to determine the sovereignty of North America commenced in 1754. In view of the French claims and en-

croachments, a congress of delegates from the several colonies convened at Albany in June of that year to decide upon measures of general defence. A plan of union, drawn up by Dr. Franklin, was adopted by the delegates; but it was rejected by the colonial legislatures to which it was submitted, as conferring too much power upon the crown, and by the crown as conceding too many popular rights. Owing to these mutual jealousies no plan of union was adopted, and in consequence, during the first years of the war, a series of disasters threatened the entire subjugation of the British colonies of North America. The war involved nearly all the colonies, and its records belong to the general history of the country. Along the frontiers of New York the French had erected fortresses on Lake Champlain, at Frontenac (now Kingston) on the St. Lawrence, and at Niagara. The English advanced posts were at Fort Edward on the Hudson, and at Oswego on Lake Ontario. In 1755 an expedition under Gov. Shirley of Massachusetts, directed against Niagara, proceeded as far west as Oswego, but returned without accomplishing any thing. In the same year a large force under Sir William Johnson marched against Crown Point. Arriving at the head of Lake George, he was attacked by the French under Dieskau, but the victory was finally obtained by the English, and the French force was nearly annihilated. In 1756 Oswego was taken by the French and destroyed. In 1757 Fort William Henry, at the head of Lake George, was taken by the French, and the garrison, after capitulation, were nearly all massacred by the Indians. In 1758 Abercrombie at the head of 16,000 men, the largest and best appointed army ever raised in America, was defeated in an attack upon Ticonderoga; and during the same year Col. Bradstreet marched through the wilderness and took Fort Frontenac. In 1759 Niagara was taken by Gen. Prideaux and Sir William Johnson, and Ticonderoga and Crown Point were abandoned upon the approach of an English army under Gen. Amherst, leaving no French force within the limits of the colony. During the last years of the war, under the administration of Pitt, the English pursued a liberal policy toward the colonies; but upon the conquest of Canada in 1760, they recommenced aggressions, which provoked opposition. Notwithstanding the presence of a larger body of royalists than in any other colony, New York fully shared in the indignation caused by the oppressive acts of parliament, and entered zealously into the measures proposed for common defence. In Oct. 1775, Tryon, the last royal governor, abandoned the province and took refuge on board a British man-of-war. In May of that year Ticonderoga and Crown Point had been surprised and taken by a party of "Green Mountain Boys" under Ethan Allen. In July an army under Generals Montgomery and Schuyler passed down Lake Champlain to invade Canada, and in the succeeding spring the same

army, defeated and broken, retreated over the same route. In Feb. 1776, an American force took possession of New York; in August the disastrous battle of Long island was fought, and immediately afterward New York and its environs fell into the hands of the British. In the summer of 1777 Burgoyne invaded the province from Canada, and a British force from New York passed up the Hudson to co-operate with him. Several fortresses upon Lake Champlain and the Hudson were taken by the enemy, but, after a series of reverses, Burgoyne's army on Oct. 17 was obliged to surrender at Saratoga. In the winter of 1777-'8 West Point was fortified, and soon became the most important fortress in America. Under the lead of Sir John Johnson, the Six Nations espoused the English cause, and continually harassed the defenceless frontier settlements. In 1779 Gen. Sullivan marched through the Indian country in western New York, and destroyed their villages. During the next two years the Indians made frequent attacks upon the Schoharie and Mohawk settlements, until the whole of that flourishing region was laid waste. On Nov. 25, 1783, New York was evacuated by the British, which was the last scene of the drama of the revolution. The original grant of New York included all lands between the Delaware and Hudson rivers, conflicting with patents previously granted to Connecticut, Massachusetts, and New Hampshire. In 1664, soon after the date of the first patent, the proprietor sold the territory included in the present state of New Jersey. The Connecticut boundary was established in 1781. The claims of Massachusetts were finally settled in 1786, by a compromise which gave New York the sovereignty of the whole territory, but yielded to Massachusetts the right of soil to that portion of the state which lies west of a meridian line passing through the 82d milestone of the Pennsylvania boundary. This line, known as the "pre-emption line," commences at the S. E. corner of Steuben co., extends along the W. shore of Seneca lake, and terminates in Sodus bay on Lake Ontario. The conflicting claims of New York and New Hampshire led to violent collisions and almost to civil war. The threatened hostilities however were averted in 1790 by the erection of the disputed territory into the state of Vermont, and the payment to New York of \$30,000. The first constitution of the state was adopted in March, 1777. This constitution was revised in 1801, 1821, and 1846, each change making the government more truly democratic in its character. Slavery, which had been much restricted since the formation of the first constitution, was finally abolished in 1817. At the close of the revolution a treaty was concluded with the Six Nations, by which a large amount of the Indian lands was ceded to the state. Settlements rapidly spread in the fertile regions of central New York, and by subsequent treaties all the lands of the Indians except a few "reservations" passed into

the hands of the whites. Upon these reservations the last remnants of the once powerful Six Nations yet linger. In 1787 Massachusetts sold to Oliver Phelps and Nathaniel Gorham the whole tract lying W. of the preemption line, containing 8,000,000 acres, for \$1,000,000. About two thirds of this tract reverted to Massachusetts, and was subsequently sold to Robert Morris. Morris sold about seven eighths of his purchase to a company of capitalists of Amsterdam, Holland, and the tract was afterward known as the "Holland Purchase." The Holland land company pursued an exceedingly liberal policy in regard to their lands. They thoroughly surveyed the whole region, built roads and mills, and by every means encouraged settlement. In consequence of this policy and the richness of the soil, western New York was filled up with unexampled rapidity. The central portion of the state and a part of Franklin and Clinton counties were set apart for military bounty lands, which were mostly drawn by soldiers of the revolution. Several large grants of land were made in the northern part of the state for the purpose of facilitating settlement, but most of the companies engaged in these enterprises failed, and the land in small parcels gradually came into the possession of actual settlers. The largest of these grants, known as "Macomb's Purchase," embraced 8,698,755 acres, in Oswego, Jefferson, Lewis, St. Lawrence, Franklin, and Herkimer counties. During the war of 1812 the frontier settlements were constantly exposed to attacks of the British, and several serious engagements took place along the borders. Sackett's Harbor, the principal American naval station on Lake Ontario, was once attacked unsuccessfully, and from it several expeditions were sent out against various points in Canada. Previous to the revolution no provisions were made for a general system of education. King's (now Columbia) college in New York city, founded in 1754, was the only incorporated educational institution in the colony. But after independence was won education received early attention. In 1787 Gov. Clinton in his message to the legislature recommended immediate action upon this subject; and during the session the "Board of Regents of the University," a body to take charge of all educational matters, was created. In 1795 a law was passed for the purpose of encouraging and maintaining common schools, and the sum of \$50,000 was annually appropriated for 5 years for their benefit. The success of the experiment was so complete, that the appropriation was continued. In 1812 a complete common school system was reported by commissioners appointed for that purpose, and adopted by the legislature. Since that time many changes have been made in the system, most of which have had the tendency to extend the influence of the schools and to place them on a firmer foundation. In 1796 the "Western Navigation Company" was incorporated. This company built locks around the rapids upon the Mohawk,

and dug a canal across the portage at Rome, so that laden boats could pass from the ocean to Oneida lake, and thence by the outlet of that sheet of water to Lake Ontario. Various plans were brought before the public from time to time for improving this channel of navigation and for building locks around Niagara falls so as to unite the waters of Ontario and Erie. In 1800 Gouverneur Morris conceived the bold plan of bringing the waters of Lake Erie to the Hudson by means of a canal directly through the centre of the state. In 1808 James Geddes made a partial survey of the proposed route, and gave a report highly favorable to the enterprise. De Witt Clinton soon afterward investigated the matter, and from that time forward gave to the project the whole weight of his influence. The war of 1812 caused a suspension of the work, but upon the return of peace in 1815 the discussion was vigorously resumed, and in 1816 a law was passed authorizing the construction of the canal. The work was actually commenced in 1817, and the canal was finished in 1825. It speedily became the great channel of trade and emigration, and poured into New York city the rich streams of traffic which have made it the commercial metropolis of the western continent. The state has been covered with a network of railways, rendering communication between distant points easy and rapid. The early attention paid to internal improvements, and the consequent development of internal resources, gave to New York the impetus which has placed it first in commercial importance, and given to it the name of "The Empire State."

NEW YORK (called by the Dutch New Amsterdam), the chief city of New York state, the commercial emporium of the United States, and the most populous city in the western hemisphere, situated at the mouth of the Hudson river, 18 m. from the Atlantic ocean; lat. (of city hall) 40° 42' 48" N., long. 74° 0' 8" W. The city and county are identical in limits, and extend over Manhattan island, Randall's, Ward's, and Blackwell's islands in the East river, and Governor's, Bedloe's, and Ellis's islands in the bay; the last 3 are occupied by the U. S. government. Manhattan island, on which stands the city proper, is 18½ m. long, and on an average 1½ m. wide, having an area of nearly 22 sq. m. or 14,000 acres. The East river islands make about 300 acres, and those in the bay 100 more. Manhattan or New York island is bounded N. by Spuyten Duyvil creek and Harlem river, which separate it from the mainland of the state, E. by Long Island sound and the East river, S. by the East river and the bay, and W. by the Hudson river. The island was originally very rough, a rocky ridge running from the S. point northward, and branching into several spurs, which united after 4 or 5 m., culminating in Washington heights, 288 feet above tide water, and a bold promontory of 180 feet at the extreme N. point. These ridges are composed of primitive gneiss, mixed

with granite, hornblende, slate, and mica. Nearly all the rock on the island shows evidence of violent upheaval, the dip of strata varying from 10° to 60° , and the ranges being frequently broken laterally. Most of the stone is unfit for building purposes, being coarse and brittle. The southern part of the island, and the shores in some places, are alluvial sand beds. The few swampy places are disappearing before the constant grading and filling for new or improvement of old streets. A deep valley which crossed the island at Canal street has shared this fate. Manhattan island is by survey divided into 141,486 lots, of which about 55,000 are built upon. The city proper extends from the southern point of the island, and is compactly built for 5 m., and irregularly along the E. side to Harlem, 4 m. further. On the W. side it is almost solidly built to about 50th street, and irregularly to Bloomingdale, at 78th street. Thence to Manhattanville, at 125th street, there are old country seats and gardens. North of 130th street the island is compressed into a narrow ridge, now occupied by handsome rural residences, and is to be laid out in serpentine streets according to its surface.—Three wagon and two railroad bridges over Harlem river connect New York with the mainland on the north; 15 ferries connect with Long island eastward, 7 with New Jersey on the W., and 2 with Staten island, 7 m. S. W., beside many steamboats not regular ferries, running to 40 or 50 small places in the vicinity. The amount of travel by ferries is enormous. On 4 routes to Brooklyn—Fulton, Wall, South, and Hamilton avenue—there are 20 boats, making about 550 trips per day, at intervals from 6 to 20 minutes, carrying a daily average of 70,000 foot passengers (35,000 each way) and 2,750 vehicles; all the other eastern ferries carry about two thirds as many, making a transit to and from Long island of about 120,000 persons and 5,000 vehicles daily. The first steam ferry boat on this river was the Nassau, started in the summer of 1812; the largest boat now is the Atlantic, of 700 tons and 160 horse power, elegantly fitted, and, like nearly all the others, lighted by gas and warmed by steam. On the W. side of the city, 8 lines run to Hoboken, one to Jersey City, and 2 or 3 to other points. The Hoboken lines have 7 boats, starting every 8 to 30 minutes, making about 800 trips per day, and carrying about 9,000 foot passengers and 700 vehicles. During the summer months Hoboken is a favorite rural resort, much frequented by Germans; and then the daily travel often reaches 20,000 each way. The first steamboat on this route started in 1822. On the Jersey City ferry there are 8 large boats, running at intervals of 10 to 30 minutes, and carrying about 80,000 passengers, or 15,000 each way, daily, of whom about one half are to and from the western and southern railroads. The railroads diverging from New York are: to the north, the Hudson river, the Harlem, and the northern New Jersey; to the east, the New Haven and the Long island;

to the south, the New Jersey, the Camden and Amboy, and the Staten island; to the west, the New Jersey central, the Morris and Essex, and the New York and Erie. These roads run about 100 passenger and 25 freight trains per day to points from 10 to 460 m. distant, and bring 8,000 to 10,000 passengers daily. The principal steamboat routes are: northward up the Hudson river, 150 m., with 8 through and 5 or 6 way boats each way daily; eastward through Long Island sound to Bridgeport, New Haven, Hartford, Groton, Newport, and Fall river, 5 regular lines of large boats; and southward, a line to Cape May during the summer season. There are many more irregular lines and single boats adding to the throng, so that by water and land about 20,000 persons are daily brought to the city during the height of the season for pleasure travel, exclusive of those arriving by regular ferries. There are 7 steamship companies, with large capital, running steamers to Richmond, Charleston, Savannah, New Orleans, Havana, Aspinwall, and on the Pacific to San Francisco. New York is well provided with docks for the repair of shipping, there being 5 or 6 on the East river side ready for use, and capable of raising the largest sailing vessels. There are 60 piers on the Hudson, and 70 on the East river. Telegraph lines radiate from New York to every part of the Union and the British provinces; and by an arrangement made by the leading daily newspapers of the city, very full intelligence of all important transactions throughout the world, as well as news by steamers which touch at distant ports, is forwarded instantly to New York. There is a local line to Brooklyn, recently established. Internal travel is by means of horse rail cars and omnibuses. There are 6 city railroads running through the 1st and 2d, 3d, 4th, 6th, 8th, and 9th avenues, and the Bowery, Chatham, Varick, Hudson, Canal, and Greenwich streets, and West Broadway. They all terminate near the city hall, except the 2d avenue railroad, which runs to the Williamsburg ferry at Peck slip. The 2d avenue and 3d avenue lines have each 70 cars in use, the 4th avenue 42, the 6th avenue 69, the 8th avenue 61, and the 9th avenue about 40. They make trips every 2 minutes during the morning and afternoon travel; the fare is 5 cts., and on the 2d and 3d avenues 1 ct. additional from 61st street to Harlem (128th street). In 1859 the 2d, 3d, 4th, 6th, and 8th avenue roads carried 32,723,351 passengers, at an expense of \$1,087,567; receipts, \$1,738,556. There are 24 lines of omnibuses, comprising about 570 stages, of which more than half run through Broadway, and nearly all through some portion of that street. There are also 845 hackney coaches.—The harbor of New York is one of the finest in the world. The bar is at Sandy Hook, 18 m. from the city, and has 2 ship channels, from 21 to 32 feet at low, and 27 to 39 at high tide, admitting vessels of the heaviest draft, the Great Eastern having passed 4 times without danger or diffi-

city. The lower bay is a safe anchorage, of triangular form, from 9 to 13 m. on each side, the N. E. angle opening into the upper or New York bay, through the Narrows, a deep channel between Long island and Staten island, about 1½ m. long by 1 m. wide. The upper bay is an irregular oval, about 8 by 5 m., opening northward into the Hudson river, eastward through the East river into Long Island sound, and westward into Newark bay. The rivers immediately around the city are deep, so that the heaviest ships can approach any of the wharfs, while the bottom affords good anchorage, and the tidal currents keep the channels free from ice. Tides rise from 4 to 6 feet at the piers. For defence there are, at the Narrows, Forts Hamilton, Lafayette, Richmond, and Tompkins, and batteries Hudson and Morton, with 457 heavy guns requiring 2,170 men; in the upper bay, on Governor's island, Fort Columbus, Castle William, and the South Battery, with 200 guns and 800 men; on Bedloe's island, Fort Wood, and on Ellis island, Fort Gibson, with 100 guns and 430 men; at Throg's Neck, in the sound, Fort Schuyler, with 318 guns and 1,250 men; while at Sandy Hook new works for 800 guns and 1,250 men are in progress. There is also under construction at Hoboken an immense floating battery

(see BATTERY); and there are usually several ships of war at the Brooklyn navy yard.—The growth of New York has been extremely rapid. The population in 1656 was 1,000; in 1756, 10,881; in 1800, 60,489; in 1820, 123,706; in 1830, 202,589; in 1840, 312,852. The following table gives the numbers furnished by the last 3 censuses:

Wards.	1830.	1840.	1850.
1.....	84	88	18,129
2.....	85	89	2,507
3.....	86	90	8,787
4.....	87	91	21,804
5.....	88	92	22,541
6.....	89	93	24,000
7.....	90	94	40,008
8.....	91	95	27,719
9.....	92	96	44,808
10.....	93	97	29,081
11.....	94	98	26,642
12.....	95	99	29,647
13.....	96	100	22,917
14.....	97	101	22,087
15.....	98	102	27,508
16.....	99	103	45,128
17.....	100	104	73,905
18.....	101	105	57,484
19.....	102	106	22,841
20.....	103	107	27,554
21.....	104	108	49,008
22.....	105	109	21,724
Total.....	515,547	622,310	814,297

The state census of 1855 gave the following distribution of the population at that time:

Wards.	Popu- lation.	White males.	White females.	Single.	Married.	No. of families.	Native born.	Non- natural- ized.	No. of colored.	Born in	United States.	Ireland.	Ger- many.	Eng- land.	France.
1.....	12,406	19	6,420	7,008	5,609	2,448	879	1,425	6,008	4,267	6,267	1,979	885	187	
2.....	2,349	29	1,294	2,325	704	484	800	280	1,254	1,372	1,164	844	147	59	
3.....	7,908	86	2,970	6,766	1,898	1,012	2,000	884	2,765	4,118	2,228	714	291	140

There were 11,840 colored persons, 22,845 widows, 5,894 widowers, 14,784 land owners, and 25,856 who could neither read nor write (of whom 1,968 only were born in the United States, and 21,878 in Ireland). As to nativity, 232,155 were born in the city, 20,000 in other parts of the state, 41,565 in other states, 2,040 in Canada, 916 in other British North American provinces, 1,121 in the West Indies, 170 in South America, 8,487 in Scotland, 985 in Wales, 174 in Belgium, 756 in Holland, 1,586 in Prussia, 331 in Austria, 978 in Switzerland, 968 in Italy, 343 in Spain, 163 in Portugal, 1,200 in Poland, 116 in Prussia, 227 in Norway, 554 in Sweden, and 227 in Denmark. There were 411 deaf and dumb, 316 blind, 655 insane, and 52

idiotic, including those in the several asylums. The return of dwellings gave 1,617 of stone, 29,997 of brick, 10,595 framed, 833 mixed—total 42,652, valued at \$278,481,811.—Most of the buildings erected within a few years, along Broadway and in the lower portion of the city, extend from street to street, or to the centre of the block, covering the entire ground space, with a height above the ground of 5, 6, and 7 stories, and 2 stories below the surface, with well lighted vaults reaching nearly to the middle of the street. Brick is still much used for the cheaper class of dwellings and workshops, but seldom for more elaborate structures. Broadway, the great central thoroughfare, is fast becoming a street of palaces occupied as stores

and shops. In the summer of 1860 there were within half a mile of the park new buildings in progress to the value of more than \$1,000,000. Broadway is 6 m. long and 80 feet wide, and upon it are nearly all the principal hotels, places of amusement, and great retail shops. It is the favorite promenade of beauty, fashion, and curiosity. Wall street, less than half a mile long, is the money centre of America. It contains the custom house, exchange, and many fine bank buildings. Fifth avenue is noted for the magnificence of its private residences, to which it is almost entirely devoted. It has also some handsome churches. Each of the avenues from 1st to 12th is 100 feet wide, and is, or will be, nearly 8 m. long, except the 6th and 7th, which are cut off by the central park. The cross streets, at right angles with the avenues, vary from $1\frac{1}{2}$ to $2\frac{1}{4}$ m. in length, and are 60 feet wide, except about every 10th one, which is 100 feet wide. The avenues are about 1,000 feet apart, the cross streets 260. The lower part of the city is less regular, and a few streets are crooked and narrow; but these are constantly being widened and extended at immense cost. The Bowery, a wide street, is the main thoroughfare for the east side, as Hudson street is for the west; and these great avenues, with their hundred lateral streets, pour into lower Broadway in the morning and return at night a crowd of people and vehicles unequalled by any other city on the continent. There are altogether 645 streets and places laid out, and most of them opened and paved.—Among the public buildings is the city hall, in the park, 216 by 105 feet, and 3 stories high; it is a handsome edifice of the Italian style. The front is of white marble, and the rear of brown stone. It was erected from 1803 to 1812, at a cost of \$216,000, and is occupied by the mayor, common council, and other public officers. The "governor's room" in the 2d story contains Washington's writing desk and chair, and a gallery of paintings embracing portraits of the mayors of the city, state governors, and leading federal officers and revolutionary chieftains, mostly by eminent artists. It has also a very fine portrait of Columbus. North-east of the city hall is the new court house, of brown stone, 8 stories high, and 105 by 72 feet. Near this is a similar edifice 70 by 55 feet, and also occupied by law courts, offices, &c. The rotunda, erected in 1818 by Vanderlyn for a panorama, was occupied after the great fire of 1835 by the post office, and is now used by the Croton water commissioners and the almshouse department. East of the city hall is the hall of records, a massive stone edifice, once used as a prison, and now occupied by the finance department and the register of deeds. The custom house, situated in Wall street, is of white marble, fire-proof, 200 feet by 90, and 80 feet high, with Doric porticos of 8 columns on Wall and Pine streets, and a granite roof. The rotunda is 60 feet in diameter, and the dome is supported by 16 Corinthian columns. Its cost was \$1,175,000. The

merchants' exchange, also in Wall street, is 200 by about 160 feet, and 77 feet high, with a dome 124 feet high. It is of Quincy granite, with a portico having 12 front, 4 middle, and 2 rear columns, each of granite, 88 feet high and $4\frac{1}{2}$ feet in diameter. The rotunda is 80 feet high, and the dome is supported on 8 pilasters of fine Italian variegated marble. The cost of the building and ground was \$1,800,000. The U. S. assay office in Wall street is a substitute for a mint. New York receives more than $\frac{1}{5}$ of the domestic product of gold. The assay office in 5 $\frac{1}{2}$ years received in bullion \$105,091,186.61, made into bars \$89,400,266.70, and sent \$36,695,532.80 to Philadelphia to be coined.—There are many fine churches, especially in the central portion of the city, and an immense Roman Catholic cathedral has been commenced in 5th avenue by the Most Rev. Archbishop Hughes. The finest church edifice is Trinity, in Broadway opposite Wall street. It is in the Gothic style, built of brown stone, 192 feet long, 80 feet broad, and 60 feet high, with a spire 284 feet high. It has rich stained windows, and a good chime of bells. It is a free church, open every day. St. Paul's, also in Broadway, is 151 by 73 feet, and has a spire 203 feet high; the front and rear are of brown stone, and the sides of gray stone colored to match; the pediment contains a white marble statue of St. Paul, and below is the monument of Gen. Richard Montgomery. St. John's, in Varick street, is of brown stone, and has a graceful spire; it is 132 by 80 feet. St. George's, in Stuyvesant square, is 170 by 94 feet, with double spires; it is in the Byzantine style, and is one of the most capacious churches in the city. St. Thomas's, in Broadway and Houston street, is a plain rough stone building 118 by 62 feet. Grace church, in Broadway, near Tenth street, is one of the showiest buildings in the city; it is of white freestone, and the interior is exceedingly elaborate with carved work and stained glass. Trinity chapel, in 25th street, 180 by 54 feet, has an interior of Caen stone, with a blue ceiling, rich stained windows, tiled floor, and movable seats. All the above-named churches are Episcopal. The first Baptist church, in Broome street, is of blue stone with battlements of brown stone in the Gothic style, 99 by 75 feet. The Dutch Reformed church in 4th street is a massive plain building, 110 by 75 feet, with a conical spire. The Washington square Dutch Reformed church is a Gothic building of rough granite, with square towers. The Roman Catholic church of the Holy Redeemer, in 8d street, is very large and costly, and richly decorated inside with marble columns and a magnificent altar. The first Presbyterian church, in 5th avenue, is 119 by 80 feet, and has a spire 160 feet high. The Congregational church in 84th street and 6th avenue is a fine new Gothic edifice, with elaborate ornamentation. The Madison square Presbyterian church is another elegant building. St. Paul's M. E. church, in 4th avenue, is Romanesque, of white freestone

or marble, 146 by 77 feet; the spire is 210 feet high. The Unitarian church of the Messiah, in Broadway, is a massive rough granite building, 100 by 74 feet, with a square tower. The Presbyterian church in 10th street and University place, of reddish stone, is a Gothic building, 116 by 65 feet, with a spire of 184 feet. The 4th Universalist church, in Broadway near Spring street, is of brick, 110 by 77 feet, and richly ornamented inside. The free Episcopal church of the Holy Communion, in 6th avenue and 20th street, is of sandstone, cruciform in plan, 104 by 66 feet, with a turret 70 feet high. The 5th avenue Reformed Dutch church is an elegant white marble building, with a tall spire of the same material. Calvary Episcopal church in 4th avenue and 21st street, is a large and handsome edifice of brown stone, with double towers. On the corner below is the Unitarian church of All Souls, of red brick and cream-colored stone in alternate layers, with variegated marble door columns. The Congregational church of the Puritans, in Union square, is of Romanesque style, built of white stone, with one square and one Chinese peaked tower. St. Peter's Catholic church, in Barclay street, is a massive granite building, with an Ionic portico and 6 granite columns, with a statue of St. Peter. The oldest church edifice is the North Dutch in William street, between Fulton and Ann, erected in 1769. The latest official church returns are given in the following table:

number of places of worship in the summer of 1860 was 274, including about 25 mission stations. The entire number of seats would accommodate nearly one third of the population of the city.—New York possesses an excellent system of free schools, and every facility is afforded by large and commodious school houses, free books and materials, and competent teachers, for the education of all children within its boundaries. These schools are managed by a board of education of 44 members, and a local board in each ward of 2 commissioners (who are members of the general board), 2 inspectors, and 8 trustees, all serving without pay. There are 52 ward or grammar schools, 85 primary schools, 8 schools for colored children, 12 corporate schools, 4 normal schools, and the free academy—in all, 112 schools. The free academy, a large and well endowed establishment, is intended to furnish the means of a full collegiate education to deserving pupils from ward schools. It has 29 teachers, 9 of whom are members of the faculty. In 1859, 880 pupils were under tuition, 325 were admitted, and 80 graduated. The library has 7,170 volumes, beside text books. In its 10 years' existence the academy has taught 2,762 pupils. The 52 ward schools are subdivided into 44 grammar schools for boys, 45 for girls, 8 for both sexes, and 46 primary departments. In 1859, 188,688 pupils were registered, with an average attendance of 51,489. For a portion of the winter there were 24 male and 20 female evening schools in operation, with 15,351 pupils; and all the year 12 specially incorporated schools with 7,809 scholars. The aggregate school registry shows 168,828 children. The expense of this instruction was \$1,246,000; of which teachers' salaries took \$617,129, new houses and repairs \$368,946, fuel \$29,530, books and stationery \$72,486, free academy \$50,112, evening schools \$69,089, and normal schools \$9,156. Of this money, \$207,883 came from the state at large, and \$1,038,667 from city taxation. To the school tax of the state at large the city contributed \$191,684 more than she received from it. More than $\frac{1}{4}$ of the attendants in evening schools were persons too old to go to day schools; 2,100 were over 21 years of age. Teachers' salaries range from \$1,500 for male principals to \$250 for good female teachers. More than $\frac{1}{4}$ of the instructors are women. Most of the school houses are 40 or 50 feet front, 100 feet deep, and 3 or 4 stories high; and some are of elegant appearance. There are, beside the public schools supported by taxation, about 88 Roman Catholic free schools, 8 of them taught by brothers of Christian schools, 12 by sisters of charity, 1 by ladies of the Sacred Heart, 1 by sisters of mercy, 1 by sisters of Notre Dame, and 1 by sisters of St. Dominic. They have from 12,000 to 15,000 pupils. The same denomination have, of higher schools, St. Xavier's college, under the Jesuits; St. Vincent's academy, and the academy of the Holy Infancy, brothers of Christian schools; and

tate worth \$1,192,850, and pay for clergymen's salaries \$438,063. Since this return there has been an increase of 46 church organizations, and a number of expensive edifices, raising the valuation to more than \$15,000,000. The actual

convents and academies of the Sacred Heart. Columbia college, the oldest college in the state, situated in 4th avenue and 50th street, had at the last report 178 students and 12 professors; the number of students graduated during the year was 82. Its property amounts to nearly \$2,000,000, chiefly in real estate. (See COLUMBIA COLLEGE.) Connected with it is the college of physicians and surgeons, in 4th avenue and 28d street, founded in 1791 and chartered in 1807. The building is of brick, and rather plain in appearance. It has a good library and a valuable physiological museum. There are 11 professors and 198 students, and the number of graduates at the last commencement was 48. It has no debts, and is supported by tuition fees and voluntary donations. It became attached to Columbia college in Oct. 1860. The university of the city of New York, a Gothic white freestone structure in Washington square, 180 by 100 feet, 4 stories high, with octangular 5 story turrets at the angles, was founded in 1881, and in 1889 had 850 pupils and 27 professors and teachers; the number of graduates was 28. It has a special law department, and a separate medical college. Its property is valued at \$212,000. The medical department in 1889 had 18 professors, 411 students, and 124 graduates. The New York medical college, in 18th street near Broadway, founded in 1851, has 18 professors and 92 students, and had 82 graduates in 1889. The metropolitan medical college is a new institution not fully established; it has 7 professors.—There are two extensive theological seminaries in the city. The first, known as the general theological seminary of the Protestant Episcopal church in the United States, was established in 1819 at New Haven, Conn. It was soon after removed to New York, and chartered by the legislature in 1822. All the bishops of the church are *ex officio* trustees, in common with clerical and lay trustees from every state in which the church is organized. Prof. Clement C. Moore gave a block of ground in 9th avenue and 20th street to "promote the establishment and endowment, and aid in the support of a seminary for the education of young men designed for holy orders in our church," and upon this ground 2 substantial stone buildings, 50 by 110 feet, were erected soon afterward. This real estate is now worth more than \$500,000. In 1860 there were 54 students, 26 having been admitted during the year. The studies are entirely of a theological character, designed to qualify graduates for holy orders. The library numbers nearly 14,000 vols. The union theological seminary (Presbyterian) was founded in 1836, chartered in 1889, and is open for students from every denomination of Christians; but the applicant must be a member in good standing of an evangelical church, and a graduate from college, or able to pass an examination in the usual college branches. The course of study occupies 3 years, and is entirely of a theological nature. The edifice, of plain brick, is in University

place, near Washington square; it contains a chapel, 4 lecture rooms, a library, and private rooms for about 80 students. The students have formed a boarding association, reducing the cost of living to \$2.25 per week. A general charge of \$10 a year is all that is demanded by the seminary. There is a faculty of 5 professors; a senior class of 38, middle 49, junior 58—141 students, 128 being college graduates. Whole number of alumni 507, of whom 86 have died. The library has nearly 24,000 vols.—Rutgers female institute is one of the principal private academies for girls. It occupies a handsome brick edifice in 5th avenue, opposite the distributing reservoir, has an endowment to the value of \$35,000, and affords a first class academic education. In 1889 there were 247 pupils. The Spingler institute, in 5th avenue, is another school for girls; and there are many others of a private character, less extensive but equally meritorious. The oldest school in the city is that of the Reformed Dutch church, founded in 1688, and still a flourishing academic institution. The Protestant Episcopal church school, founded in 1710, will soon come into an immense property by the testament of Dr. John Baker, who gave 46 acres of land on the East river shore near Yorkville to endow this as a charity school. There is in the Cooper institute an academy of design for women; and many other commercial and literary schools offer easy and generally cheap facilities for general and special education.—The New York hospital, the oldest institution of the kind in the state, was chartered by George III. in 1771. It is in Broadway above the city hall, approached through an avenue of noble elm trees, and has 8 large buildings, respectively 124 by 86, 128 by 90, and 93 by 63 feet, and each 4 stories high. The grounds cover about 2 acres. The asylum for the insane at Bloomingdale, opened in 1821, is a branch of the hospital; it has about 40 acres of ground and a fine botanical garden. In 1889 the total receipts of the hospital were \$120,590.87; expenses, \$112,781.04. Patients treated, 2,568; cured 1,771, relieved 269, discharged 213, died 815; of the deaths 174 were from incurable accidents; 1,825 were surgical cases. Of all the patients, 785 were natives, 1,045 Irish, 808 German, and 175 English. In 80 years there were 74,257 patients, of whom 64,726 were cured, 4,974 relieved, and 7,469 died. The asylum for the insane in 1889 treated 283 patients, of whom 55 recovered, 82 improved, and 18 died; in 10 years there were admitted 1,067. There are 5 principal free dispensaries, the oldest founded in 1791. In 1889 there were 184,418 patients treated (62,067 native, 72,351 foreign), of whom 925 died; 12,667 vaccinations, and 262,688 prescriptions; whole expense, \$21,468. The New York woman's hospital, for the exclusive treatment of diseases of women, is a new and very promising institution, the only one of the kind in the country. Its chief importance is due to some recent discoveries of

great value in the cure of affections peculiar to the sex. There is also a lying-in asylum in Marion street. The institution for the deaf and dumb, incorporated in 1817, is at Washington heights, and is the largest of the kind in the country, employing 15 teachers, and meeting with gratifying success. The grounds comprise 37 acres. In 1859 there were 308 pupils, of whom 164 were males and 144 females. The institution for the blind, in 9th avenue, a handsome and spacious structure of stone, has 19 teachers, and in 1859 took care of 205 inmates or pupils, many of whom are well educated, and good workmen in the trades taught on the premises. The grounds are 800 by 200 feet; the building is 175 feet front, and 3 stories high. The society for the reformation of juvenile delinquents has an important reformatory institution on Randall's island, to which juvenile criminals and vagrants are sent. It is a state institution, but most of the inmates are from the city. In 8 years 2,641 children were received (2,177 boys and 464 girls), of whom 1,548 were Irish, 218 German, 150 English, 280 from other foreign countries, and 445 American. The juvenile asylum in 175th street supports and educates children from 7 to 14 years of age, placed there by parents and guardians or committed by magistrates. The children's aid society, for sending to the country destitute children, is doing much good, in connection with the local missions in the Five Points (a section of the 6th ward inhabited until within 5 years almost exclusively by the lowest prostitutes, thieves, and beggars) and other disreputable portions of the city, the ragged schools, and private charities. The association for the relief of the poor, started in 1843, has an organization which thoroughly supervises the city, and relieves all deserving poor not otherwise provided for. In 1859 \$44,856 was thus spent; 9,281 families and 44,557 persons were relieved, and 47,000 visits were made, nearly all in January, February, and March. This association divides the city into 382 sections, having in each a gratuitous visitor. For 10 years, from 1845 to 1855, there was no increase in pauperism, though the population increased 67 per cent. From 1855 to 1857 pauperism materially increased, through financial revulsion; but since that year the current has set the other way, and the net result of 17 years shows an improvement upon indigence as compared with the increase of population of 142 per cent. Of 44,950 persons relieved by this association from 1854 to 1860, 81,002 were Irish, 4,872 German, 2,012 English and Scotch, 640 other foreigners, and 6,424 native-born. The latest summary shows that from Oct. 1859, to Oct. 1860, 8,031 families and 35,942 persons were relieved, 40,866 visits made, and \$40,565.10 spent. The New York orphan asylum, on the bank of the Hudson at Bloomingdale, is a fine Gothic building 120 feet by 50, with 15 acres of land. The society was organized in 1806 by ladies, and is supported by private donations.

The Leake and Watts orphan house in 112th street is a large and handsome edifice, delightfully situated in a plot of 26 acres, and has an income sufficient for the support of 250 children. At the Five Points the house of industry and the Five Points mission have to a great degree reformed that notorious locality, and extirpated most of the dens of degradation and crime once abounding there. Among the less prominent benevolent institutions are the prison association for the reformation of discharged convicts; the association for the relief of aged and indigent females; association for the benefit of colored orphans; ladies' home missionary society; American female guardian society; St. Luke's home for indigent Christian females; Protestant half orphan asylum; Magdalen female benevolent society; house and school of industry; marine society, the oldest society in the state; sailors' snug harbor, a retreat for seamen on Staten island; seamen's friend society; society for relieving children of seamen; mariners' family industrial society; St. Luke's hospital; eye and ear infirmary; ophthalmic hospital; and children's hospital and nursery. The principal Roman Catholic institutions, beside the Jesuit college of St. Francis Xavier, are the convent of Redemptorists or Order of the Most Holy Redeemer, in 8d street, attached to the church of that title; the community of missionary priests of the congregation of St. Paul the Apostle (a congregation founded in New York in 1859), in 59th street near the central park; the communities of brothers of the Christian schools in 2d street, attached to St. Vincent's academy, and in 181st street (Manhattanville), in connection with the academy of the Holy Infancy; the communities of ladies of the Sacred Heart connected with their seminaries for young ladies in 17th street and Manhattanville; the convent of the sisters of mercy in Houston street, with an asylum or house of protection for destitute women, and a free school; the houses of the sisters of charity, who direct an orphan asylum for girls in Prince street and one for boys in 51st street and the 5th avenue, an industrial school and a girls' school in 42d street, and St. Vincent's hospital in 11th street; St. Vincent's (French) orphan asylum in 24th street, under the patronage of the ladies of St. Vincent de Paul; the convent of the school sisters of Notre Dame in 8d street, where there is a school and an asylum for the care of 200 children during the absence of their parents; and the convent of the sisters of the Good Shepherd, who devote themselves to the reformation of fallen women, and have from 50 to 75 inmates in their asylum. There are also about 30 private benevolent societies, beside masonic, odd fellows', druids', united American, sons of Herman, German Verein, Hebrew benevolent, sons of temperance, and other lodges. The masonic order have about 100 lodges in the city. A founding hospital has been projected, and the edifice is now building. The Cooper

institute for moral, intellectual, and physical culture (see COOPER, PETER), is a fine edifice of 6 stories, 195 feet on 4th avenue, 148 on 8th street, 155 on 3d avenue, and 86 on 7th street. In the basement is a large lecture room 125 feet by 82, and 21 feet high, and in the 3d story is another of the same size. There are rooms for libraries, philosophical apparatus, and study, a free reading room, &c. The whole establishment is rated at over \$500,000. The Bible house in Astor place occupies an entire block, with a front of 711 feet, and a depth of 50 feet; it is 6 stories (74 feet) in height. The American Bible society, next to the British and foreign the largest in the world, was founded in 1816, and had an income in 1859 of \$435,956. For the advancement of agriculture and science there are the American institute with its farmers' club, and the mechanics' institute, the former holding annual fairs in the city.—The Astor library, now having 100,000 volumes, was founded by a legacy from John Jacob Astor in 1848. This library is for study and reference, no books being taken away. (See ASTOR LIBRARY.) The mercantile library, in Astor place, organized in 1820, is a lending library, and has about 55,000 volumes; its files of magazines and leading newspapers are very full. The association is composed of merchants and clerks, who become members on payment of a small initiation fee and annual dues. Other persons may acquire the privileges of the library and reading room by paying \$5 annually. The society library, established in 1754, has a fine building 70 by 100 feet in University place, with 40,000 volumes of history and general literature. The historical society has a handsome fire-proof edifice in 2d avenue, with about 30,000 volumes, particularly of American history; it was founded in 1804. The other principal libraries are: union theological seminary, 24,000 vols.; apprentices' library, 19,000; Columbia college, 18,000; Episcopal theological seminary, 13,500; law institute, 8,000; American institute, 7,500; free academy, 7,000; New York hospital, 6,000; mechanics' institute, 5,000; institution for the deaf and dumb, 4,185; university medical department, 4,000; printers' library, 4,000; lyceum of natural history, 3,000; geographical society, 2,450; young men's Christian association, 2,300; and there are many other small libraries, beside the public school libraries furnished by the state. The city has a very good collection, principally of law and statistical works. A woman's library, the first in the country, has been opened (1860), under encouraging prospects, with several thousand volumes of scientific and general literature. There are many very good private libraries, belonging chiefly to lawyers and clergymen.—Art is cared for by the national academy of design, chartered in 1826, with schools for the study of antique and living models, giving annual exhibitions. There are also the Düsseldorf gallery, a collection of works of that school, in the new and beautiful institute of the

fine arts in Broadway near Houston street; the international gallery; and the artists' studios, a large building in 10th street. Among the most valuable and interesting museum collections is that of Dr. Abbott, gathered during several years' residence in Egypt, where he was physician to Mehemet Ali. There are few collections of Egyptian antiquities more valuable than this. In 1860 it became the property of the historical society. The opera house, or academy of music, in 14th street near Broadway, is a handsome building of painted brick, with stone facings. It is 121 by 114 feet, very elaborate and ornate inside, with 4 tiers, and seats for 4,700 persons. Except the two Bowery theatres and Barnum's museum, the other places of amusement are of mean exterior, standing in back streets, with simply an entrance from Broadway. Inside, however, they are generally comfortable, and some are luxurious. With average attractions about 20,000 people nightly attend these places. The chief of them are Niblo's garden, the winter garden, Wallack's and Laura Keane's theatres, in Broadway; Bowery, New Bowery, National, and Stadt theatres, in the Bowery; Barnum's museum; and three negro minstrel halls. In summer the palace garden, Jones's woods, and many other outdoor places of entertainment, are frequented by large numbers of people.—There are 8 public and a few private parks. Among them are the Battery, 10½ acres (now being enlarged to about 30 acres), at the S. W. extremity of the city; the city hall park, 10½; Washington parade ground, 9½; union, 4; Stuyvesant, 4; Tompkins, 10½; Madison, 7; St. John's, 4; Gramercy, 1½; and the great central park of 848 acres, now being laid out. This park extends from 59th to 110th street, 2½ miles long, and from 5th to 8th avenue, ½ of a mile wide. It is to contain drives, bridle roads, foot paths, play grounds, ponds, lakes, exotic and native trees and plants, and to present all the features of a rural pleasure ground twice as large as Hyde park in London. Much of the work in the lower part is now (1860) completed or in a state of forwardness, and it already furnishes a delightful resort for thousands daily in fair weather. (See PARK.) Fountains have been constructed in the city hall, Washington, union, Tompkins, Madison, Stuyvesant, St. John's, and Gramercy parks.—The leading clubs are the union and the Athenæum in the 5th avenue, the New York and eclectic in Broadway, the century in 15th street, and the New York yacht club. The union has a large and handsome brown stone house in 5th avenue and 21st street. The hotels of New York are among the largest and finest in the world. The chief of them are the Astor, La Farge, Everett, and Brevoort houses, and the St. Nicholas, Metropolitan, Fifth avenue, Clarendon, and New York hotels; and of more than 50 other large hotels, several are not much inferior to those named. The Astor house is the oldest of the great hotels. It was built in 1839 by John Jacob Astor, then the richest man in America.

It is a massive 6 story granite building in Broadway opposite the city hall park, the front occupying an entire block, with shops in the first story. This house accommodates about 600 guests, on either the American or European plan (that is, as boarders or lodgers, or both). The St. Nicholas, opened in 1854, is 6 stories high, fronting about 275 feet on Broadway and 200 on Spring street, built of white marble and brown freestone, and has 600 rooms with accommodations for 1,000 guests. It is luxuriously furnished throughout. The Metropolitan fronts 278 feet on Broadway, with a wing on Prince street 200 by 25 feet. The main building is about 60 feet deep, 6 stories high, all of brown freestone. This, like the St. Nicholas, is elegantly furnished, and conducted on the American or full board plan. The last, and most expensive and luxurious, is the Fifth avenue hotel, at the junction of Broadway, 5th avenue, and 23d street opposite Madison square. It is of white marble, 6 stories high, fronting on 3 streets, having room for more than 1,000 guests.—There are few monumental memorials in the city, except in the churchyards. In Union square is a colossal bronze equestrian statue of Washington, executed by H. K. Brown, at the cost of an association of private gentlemen residing in the neighborhood. At the junction of Broadway and 5th avenue is a monument to Major-Gen. Worth; it is a granite obelisk, inscribed upon the shaft with the names of battles in which he was distinguished during the war with Mexico. This is the only monument erected by the corporate authorities. In St. Paul's churchyard may be seen from the street a small marble obelisk to Thomas Addis Emmet, and beneath the portico a monument to Gen. Montgomery.—There are 11 public markets, all insignificant in appearance except Tompkins market, at the junction of 3d avenue and 6th street, a fine iron building 182 by 100 feet, opened in 1860. In 1859 there were brought to the city shambles 205,272 oxen and steers and 9,422 cows, yielding about 140,000,000 lbs. of beef; 48,769 calves, 3,000,000 lbs. of veal; 504,894 sheep, or over 25,000,000 lbs.; about 400,000 live hogs and as many carcasses, making 56,000,000 lbs. of pork; in all over 224,000,000 lbs. of meat, beside beef, veal, and mutton to a large amount ready dressed, poultry in enormous quantities, game, and fish. The supply of milk from the adjacent country is about 180,000 quarts per day. The surrounding waters are noted for yielding excellent oysters in great abundance. There is no considerable supply of fish taken near the city, except of shad in the spring, when immense quantities are caught in the bay and Hudson river. The annual catch is valued at over \$100,000, though the season lasts but 6 or 8 weeks. Nowhere is the habit of eating away from home so general as in New York, owing to the great distance between residences and places of business; and this habit has made eating houses, lunch rooms, refectories, oyster

cellars, bar rooms, &c., a prominent feature of the town. They are everywhere, open day and night, and thronged by all classes, according to their quality, from the millionaire to the vagabond.—The city government is vested in a mayor, a board of 17 aldermen elected for 2 years, and one of 24 councilmen annually chosen, and constituting the common council. The controller and corporation counsel are also chosen by the people. The mayor and the heads of departments have salaries of \$5,000 per year. The mayor and aldermen appoint the street commissioner, city inspector, and Croton water commissioners. The street commissioner's department opens, extends, and alters streets, roads, parks, and wharfs, erects and repairs corporation buildings, supplies fuel, light, stationery, and other requisites to city offices, and collects assessments for local improvements. The city inspector's department cleans the streets and markets, records births, marriages, and deaths, grants permits for burial, collects market fees, and inspects weights and measures. The Croton board superintendent the supplying of water to the city, build sewers, and lay and repair pavements and sidewalks. The controller has supervision of the financial affairs of the city and county, receiving and disbursing all moneys raised by tax and assessment. The extent of this business may be inferred from the footings of the balance sheet of the general ledger for 1859, viz.: \$38,508,655.69. The actual expenditures during the year were, on city account, \$6,655,626.34, and for state and county purposes, \$3,802,878.42; total, \$9,958,504.76, of which \$9,860,926.09 was raised by tax. The city is in debt \$17,801,560, of which \$7,693,121 is for the first cost of introducing the Croton water, \$1,000,000 for land damages for the same work, \$255,600 for extending water works, \$1,679,100 for the new reservoir, \$190,000 for a new workhouse, \$402,768 for buildings blown up by the authorities at the great fire of 1835, \$5,406,971 for the central park, \$520,000 for public buildings, \$154,000 for education, and \$500,000 for docks and slips. The total amount of interest, at 5 and 6 per cent., is \$959,854. This debt is redeemable at several periods up to 1898, from a sinking fund now amounting to \$6,364,394.85. There is another sinking fund of \$185,827.52, for paying interest on the public debt. The revenues of these funds are such that it is believed that interest and principal will be paid without resort to taxation. Beside these revenues all the real estate of the city is held in trust by the sinking fund commissioners for the security of public creditors. This amounts to \$43,000,000, of which the Croton works are valued at \$15,475,000, parks \$14,761,000, piers \$3,400,000, school houses \$2,359,000, markets \$1,814,000, almshouse \$1,250,000, and ferries \$1,200,000. The leading items of city expenses are: charity and correction \$665,000, city schools \$1,246,000, street cleaning \$320,000, docks \$146,000, light \$420,000, salaries \$420,-

000; and of county and state paid by city, state schools \$400,000, police \$1,250,000, and state tax \$980,000. The rapid property growth of the city is shown in the following table of valuation and taxation for 20 years:

Large as these figures seem, they are far below the truth. In 1859 the state appointed commissioners to equalize and graduate the county and local valuation for assessments, who fixed the aggregate of real and personal estate for the city at the sum of \$856,964,491, adding that it was still deemed too small. There is a county government in addition to that of the city, vested in a board of 12 supervisors, two chosen each year, who have partial control of taxation, civil and criminal courts, and county offices. The county officers elected by the people are supervisors, 5 justices of the supreme court, 6 of the superior court, 8 judges of common pleas, 8 of the marine court, and 8 of district courts; a district attorney, county clerk, sheriff, register, surrogate, and 4 coroners. New York is politically divided into 6 congressional, 4 state senatorial, 17 assembly, 8 judicial, 22 school or ward, and 217 election districts. Aldermen are elected from assembly districts, and councilmen, 6 on a ticket, from senatorial districts; school officers and constables from wards. Supervisors, judges (except district and police justices), and other county and city elective officers are voted for throughout the city. The city forms the 1st judicial district and the 1st military division of the state. The laws are administered by a supreme court of 5 judges, a superior court of 6 judges, a marine court of 8 judges, a court of common pleas with 8 judges, 7 district civil courts, courts of oyer and terminer (held by a supreme court judge), the general sessions and special sessions, and 4 police courts, beside the circuit and district courts of the United States. In 1858 there were in the city criminal courts of record 608 convictions, 207 being natives. In the special sessions, of 11,469 convicted, 1,742 were natives, 10,868 intemperate, 4,784 males, and 6,685 females; and of the latter 2,849 were vagrants.—There is a lively military spirit among the young men of the city, and some of the volunteer militia

regiments rival veteran regulars in their drill. There is one military division, embracing 4 brigades, 16 regiments, 119 companies, 441 officers, 529 non-commissioned officers, 4,021 privates, 169 musicians, 5 general officers, and 21 in the staff; total at last inspection, 5,186. The full return shows a total of 6,224. There are 48 light infantry, 32 infantry, 28 cavalry, 10 rifle, and 6 artillery companies, beside an engineer corps. The state armory in the 7th avenue, just completed, is a very large brick structure with octagonal towers, and covers an area of about 80 by 150 feet. The arsenal in White street is in the Gothic style, of blue stone, 2 stories high, constructed with a view to defence as well as storage.—New York is supplied with pure water by the Croton aqueduct (see AQUEDUCT, vol. i. p. 780), from the Croton river, a small stream in Westchester co. The present receiving reservoir at 86th street, in the central park, holds 150,000,000 gallons; 2½ m. below is a distributing reservoir holding 20,000,000 gallons. A new reservoir immediately N. of that at 86th street, and also in the park, is nearly completed, having 96 acres of water surface, 36 feet deep, and holding 1,080,000,000 gallons. Up to 1860, 266½ m. of water pipes had been laid, supplying nearly every paved street in the city. The total cost of the works to 1860 was \$15,210,680; receipts in 1859, \$800,000; total receipts for water since it was introduced in 1842, \$7,485,098. The sewerage of the city is not as thorough as it should be; but there are 100 m. of sewers, some of them extensive and costly. There are nearly 200 m. of paved streets, mostly of cobblestone; but of late years square block or Belgian pavement is chiefly used, and iron paving has been employed to a very limited extent. The footways are flagged. The city is lighted by 14,451 gas lamps, which burn every night from dusk until dawn; there are three companies in operation, supplying gas at \$2.50 per 1,000 feet. The longest lighted street is Broadway and Bloomingdale road, 18½ m., with 895 lamps.—The fire department is entirely voluntary, the men receiving no remuneration except exemption from jury and military duty. By the last official report there were 1 chief engineer with 14 assistants, 2,284 members of engine companies, 1,411 of hose companies, and 582 of hook and ladder companies—total, 4,227; 50 engine, 56 hose, and 17 hook and ladder companies; and 86,000 feet of hose. Several steam fire engines have recently been introduced with success. The number of fires in 1858 was 261; the loss on buildings was \$592,657, and on stock \$514,990. The machines and men are housed in good buildings erected by the city, and furnished with gas, fuel, sleeping rooms, and baths. Since the introduction of the Croton water there have been comparatively few destructive fires. A board of five commissioners hear and determine disputes and offences in the department, and the fire wardens enforce the building and other laws for

the prevention of fires. These boards and the chief engineer and his assistants are elected by members of the department. The firemen have an invested fund of \$97,250 for the relief of widows and orphans of deceased or disabled members; the receipts in 1859 were \$40,221, and the disbursements \$38,890.—The police department extends over the metropolitan district, including New York and Brooklyn, and Kings, Richmond, and Westchester counties; it is under the absolute control of a board of three commissioners, appointed by the governor and senate. There is a superintendent for the whole district, a deputy for New York and one for Brooklyn, and 4 inspectors; and the force in New York consists of 27 captains, 110 sergeants, 48 roundsmen, 1,253 patrolmen, 101 on special duty, and 58 doormen; total, 1,597. There are 285 day and 493 night posts, 412 miles of streets in the patrol district, and 11 miles of piers. There are 27 precincts, including the detective squad. For the quarter ending July 31, 1860, there were 18,162 arrests (12,585 males, 5,627 females); offences against the person, 15,027, of which 2,918 were assaults, disorderly conduct 1,800, intoxication 7,247, street fighting 846, vagrancy 800, murder 10; among property offences were burglary 184, fraud 155, grand and petit larcenies 1,875, keeping disorderly houses 73, false pretences 59, violation of various laws 857, rioting 25. Of all the arrested, 8,986 were married and 9,176 single; 18,816 could read and write, 695 could read only, and 4,151 could neither read nor write; 3,595 were born in the United States, 9,889 in Ireland, 1,263 in England, 1,251 in Germany, 490 in Scotland, 814 in France, and 138 in Italy; and 409 were colored. Ages of males: 10 to 15, 646; 15 to 20, 1,444; 20 to 25, 2,348; 25 to 30, 2,295; 30 to 40, 8,296; 40 to 50, 1,663; over 50, 848. Ages of females: 10 to 15, 94; 15 to 20, 595; 20 to 25, 1,197; 25 to 30, 1,193; 30 to 40, 1,587; 40 to 50, 622; over 50, 389. As to occupations, 8,002 were returned as mechanics, 2,771 laborers, 1,438 housemaids, 1,247 prostitutes, 896 servants, 561 seamen, 501 housekeepers, 457 cartmen, 220 clerks, 213 peddlers, 179 boatmen, 178 hackmen, 22 teamsters, 86 drivers, 58 porters, 45 runners, 183 seamstresses, 122 merchants, 111 porter house keepers, 80 hotel keepers, 43 bar tenders, 63 grocers, 141 other liquor dealers, 101 junk dealers, 89 artists, 26 actors and 7 actresses, 20 doctors, 63 farmers and gardeners, 21 lawyers, 217 tradesmen, and 5 gentlemen. Losses by robberies amounting to \$45,059 were reported, and \$17,622 was recovered. The number of arrests is no guide to the number of offenders, since some are arrested from 5 to 20 times in a quarter for intoxication, each arrest being duly recorded. Of 671 workhouse commitments in 2 weeks for vagrancy, only 5 were for the 1st time, 311 for the 2d, 152 for the 3d, 3 for the 60th, and 4 for the 75th. The average result for a year shows the number of individuals arrested to be about

one sixth of the number of arrests. Policemen are appointed during good behavior, and officers rise from the ranks. Patrolmen are paid \$800 a year, sergeants \$900, captains \$1,200, inspectors \$2,000, and the general superintendent \$5,000. Telegraphic lines connect all the stations with the central office, at which there were received and transmitted during the quarter by their means 88,786 messages, giving notice of fires, lost persons and property, &c. There are 23 station houses (most of them built for the purpose), fitted up as lodging houses for the men, and having room also for lodging destitute or wandering persons, of whom 18,667 were accommodated during the quarter above named. A portion of the force form a harbor police, in boats, and another portion is a sanitary squad for the suppression of nuisances dangerous to health and life. This sanitary squad show that in the 6th and 7th wards there are 1,152 tenement houses, with 87,064 inhabitants, about 2,500 of whom live in a space of less than 200 cubic feet each. New York pays nearly \$1,250,000 a year for police expenses.—Three commissioners of public charities and correction have charge of paupers and criminals. The institutions under their care, with the number of inmates during the year 1859, were as follows:

Institutions.	Inmates, Dec. 31, 1859.	Admitted during the year 1859.	Natives.	Foreigners.	Deaf.	Discharged.
Alms-house	1,701	3,781	716	3,018	284	2,755
Bellevue Hospital	826	8,801	1,242	7,559	942	8,067
Island Hospital	899	8,441	892	7,549	111	8,287
Small Pox Hospital	7	184	75	66	19	111
Lunatic Asylum	658	889	85	804	56	947
Nurseries	1,845	1,148	909	289	80	1,317
Workhouse	903	4,720	88	4,540
Penitentiary	785	2,079	696	1,383	15	2,071
District Prisons	476	42,007	9,688	32,319	...	41,170

There were, at the close of 1859 (including with the above institutions the colored home, colored orphan asylum, and city cemetery), 7,982 persons in care of the department of charities and correction. In the Bellevue hospital there were 888 births. Of the children discharged from the nursery, 279 were bound out, 167 adopted, and 621 given to relatives. Of those committed to the district prisons, 25,588 were males and 16,469 females; 16,087 were married, 23,649 single, the rest widowed or unknown; 35,476 were intemperate; 15,461 could not read, 18,729 could not write, and only 3,117 were well educated. Of the foreigners, there were from Ireland 22,870, Germany 4,322, England 1,944, Scotland 900, France 892, Italy 296. The principal offences were: intoxication 11,683, vagrancy 7,055, assault and battery 2,839, disorderly conduct 2,920, petit larceny 3,160, murder 49. The commitments were chiefly for from 1 to 6 months. There were 2,278 paupers buried in the city cemetery, of whom 1,401 were natives and 877 foreigners, and 1,200 were children. Of outdoor poor, 5,046 adults and 7,812 children were relieved with money, and 29,515

adults and 45,477 children with fuel. Of the adults, 24,399 were foreign, 3,745 native, and 1,371 colored. The expenditures for the year were nearly \$800,000, of which \$28,646 was cash and \$37,746 for coal for outdoor poor, \$12,000 for nursing children, \$18,000 for the colored home and asylum, \$38,374 for dry goods, \$11,414 for medicines, and \$186,118 for provisions. The buildings in charge of the commissioners are solid and spacious. On Blackwell's island, the lunatic asylum, almshouse, penitentiary, island hospital, workhouse, and small pox hospital are all of granite quarried on the island by convicts. On Randall's island there are several large buildings for the care of foundling, orphan, and destitute children, and the house of refuge for juvenile delinquents. Bellevue hospital occupies two blocks at the foot of 26th street, East river. The city prison, or Tombs, fills a block in Centre street; it is 253 feet long by 200 feet wide, built of granite in the Egyptian style, with about 150 cells around the inside square. The city cemetery (potter's field) is on Ward's island, between Blackwell's and Randall's islands.—Nine commissioners of emigration have supervision of the landing and forwarding of immigrants, collecting commutation fees, and taking care of the sick. The landing depot is in Castle garden, at the Battery, and there is an emigrants' refuge hospital on Ward's island. In 1859, 79,322 bonded passengers arrived (32,652 from Ireland, 28,270 from Germany, 10,375 from England); 61,584 came in 322 sailing, and the remainder in 105 steam vessels. Of the immigrants, 8,510 were destined for the eastern states, 40,928 for New York, 9,991 for New Jersey and Pennsylvania, 15,790 for the western states and California, 740 Mormons for Utah, 2,200 for Canada West, and 5,066 for southern states. During the year there was an average of 676 persons in the hospital and refuge; average cost of support, \$81.20 per year each. It is estimated that since the revolution 5,430,000 passengers have entered the country from foreign ports, of whom about 3,500,000 debarked at New York. (See EMIGRATION.) These immigrants bring an average of about \$100 per head in cash; and the owners of the vessels in which they come pay toward the maintenance of the institutions designed for their benefit a commutation of \$2 each.—The quarantine establishment is at Staten island, where the health officer resides, and where ships from infected ports are detained and purified. The earliest special acts to prevent the spread of infectious diseases were passed about 100 years ago, and in 1794 a regular quarantine was established on Governor's island. A quarantine was begun on Bedloe's island in 1797; but the severity of the yellow fever the next year induced the state to authorize the purchase of 30 acres in the town of Castleton, Staten island, to which the Bedloe's island building was removed. In 1819 a more substantial building was erected, in 1823 a fever

hospital, and in 1829 a small pox hospital. As Staten island became thickly settled, the removal of the quarantine was asked for, but nothing was done up to 1856. In that year there were 769 cases of yellow fever on Staten island, the adjoining shore of Long island, and in south Brooklyn; of the 538 on Staten island, one third were fatal. In March, 1857, the legislature authorized the removal of quarantine, and land was bought at Seguine's point, 7 m. further from the city, but still on the island. Five days after the transfer, a mob burned all the buildings; new ones were put up, but they also were soon burned, and the site was thenceforward abandoned. The hostility to the regular establishment increased in strength; the Castleton board of health declared it a nuisance, and on the night of Sept. 1, 1858, the place was attacked by a mob, the sick were carried from the hospitals and laid upon mattresses in the fields, the officers and physicians driven off, and all the buildings save the women's hospital destroyed by fire; the next night the remaining hospital was similarly destroyed. The governor declared the island in rebellion, and sent troops there; but no further trouble occurred. Sheds have since been erected on the grounds, and the health officer resides there; but a floating hospital, anchored in summer about 12 m. away, receives patients suffering from yellow fever and other contagious diseases. The permanent location of quarantine is yet unsettled. There is a board of health in the city, composed of the mayor, resident physician, health commissioner, and common council, who possess summary power in all matters affecting the public health. The executive committee of this board hold daily sessions through the summer season. The ratio of mortality in New York is high, owing to the vast influx of unacclimated foreigners. In 1859 there were 21,645 deaths, of which 8,182 were of adults and 13,463 of children; 6,137, mostly adults, were of foreign birth, and 492 were colored persons; 1,575 deaths were from accidents and other causes than disease; males exceeded females by 1,633; one mulatto said to be 114 years old, one negro 107, and 3 women 109, 105, and 102. The principal diseases were: apoplexy 309, bronchitis 310, cholera infantum 1,364, congestion of the brain 489, congestion of the lungs 217, consumption 3,239, convulsions 1,816, croup 622, debility 425, diarrhoea 502, dropsy 244, dropsy in the head 907, erysipelas 141; puerperal fever 168, scarlet 840, typhoid 206, typhus 169; heart disease 456, whooping cough 853; inflammation of bowels 385, brain 468, lungs 1,167, stomach 157, throat 111; intemperance 118, marasmus 1,471, measles 261, palsy 257, teething 209; and from external causes, burned and scalded 135, various casualties 267, drowned 165, killed or murdered 28, old age 258, premature birth 374, suicide 56. The still-born, 1,331, are not included in the above totals. Since the cholera of 1849 and 1854 there has been no epidemic. Small pox and scarlet fever ran very high from

1850 to 1858, and measles from 1848 to 1858. The ratio of deaths since 1855 has been about 1 in 85. Burials, except in family vaults, have long been prohibited in the settled portion of the city, and the dead are now mostly taken to Greenwood, Evergreens, Calvary, and Cypress Hills cemeteries on Long island, New York bay cemetery on the New Jersey shore, and Trinity cemetery on the upper part of Manhattan island. —A condensed view of the statistics of manufactures, derived from the latest official returns, is presented in the following table:

The amount of capital invested by these establishments in real estate was \$21,484,002, and in machinery, \$10,995,684. Some of the most extensive branches were as follows:

Business.	Estab-lish-ments.	Hands.	Value of raw material.	Value of manufactures.
Sugar refineries.....	14	1,698	\$4,507,500	\$12,167,800
Tailors' shops.....	126	12,908	4,317,302	7,592,894
Silver ware.....	88	1,558	2,111,899	2,909,831
Steam engines.....	17	2,180	1,819,550	2,292,800
Ship building.....	25	1,778	922,616	2,568,761
Grist mills.....	6	175	2,187,300	2,497,719
Cabinet ware.....	95	2,116	685,148	2,226,794
Soap and chandlery..	81	856	1,505,571	2,220,927
Distilleries.....	10	184	1,912,800	2,218,200
Furnaces.....	87	1,895	696,925	2,146,950
Hats and caps.....	51	1,577	1,211,020	2,092,502
Pianofortes.....	38	1,185	461,215	2,000,182

Of the leading occupations, the directory for 1860 records 704 bakeries, 646 boarding houses, 80 breweries, 1,296 butchers, 918 cigar and tobacco stores, 180 fishmongers, 65 poulterers, 542 butter and milk dealers, 778 provision dealers and hucksters, 389 coffee and eating houses, 187 fruiterers, 259 confectioners, 282 flour and grain merchants, 3,624 grocers, 113 hotels, 807 oyster houses, 3,787 porter houses, 86 tea stores, 22 sugar refineries, and 469 wine and spirit merchants; 2,412 boot makers, 819 builders, 688 cabinet makers, 868 hatters, 60 carpet stores, 1,391 tailors, 223 china and glass dealers, 1,307 milliners and dress makers, and 78 shirt factories; 746 dry goods dealers, 1,278 variety stores, 258 coal dealers, 164 oil stores, 108 gas fitters, 195 furnishing stores, 569 hair dressers, 315 hardware stores, 212 iron works, 720 watchmakers and jewellers, 99 lace and 90 silk importers, 100 locksmiths, 155 lumber yards, 154 marble and stone yards, 464 painters, 121 piano makers,

207 plumbers, 100 stove stores, 108 turners, 62 umbrella makers, 107 upholsterers, and 84 whitewashers; 17 daily, 10 semi-weekly, 123 weekly, and 50 monthly newspapers, and 82 magazines and reviews; 114 stationers, 268 booksellers, 228 printing offices, and 129 private schools of note. There are also 576 agents by profession, 87 auctioneers, 128 bankers, 785 brokers, 49 pawnbrokers, 255 exchange offices, 284 blacksmiths, 87 engine and boiler shops, 167 machinists, 84 brass and 170 copper and tin smiths, 165 coopers, 481 druggists, 205 dentists, 91 nurses, 1,149 physicians, and 1,805 lawyers; 202 livery stables, 90 coach makers, 86 wheelwrights, 160 saddle and harness makers, and 222 leather dealers; 51 lithographers, 182 photographers, 288 engravers, 139 glass workers, 105 goldsmiths, 1,206 importers and commission merchants, 62 railroad offices, 80 steamship companies, 6 ship yards, 100 shipwrights, 50 riggers, 54 sail makers, 89 ship chandlers, 20 boat builders, and 95 undertakers. Nearly all these figures represent establishments instead of individuals, except in the professions. The general directory for 1860-'61 contained 150,308 names. At the beginning of 1859 the rates of wages for ordinary trades, such as carpenters, masons, and iron workers, ranged from \$8 to \$12 per week; for women as milliners, dress makers, book folders, &c., \$3 to \$7. The press of New York produces about 800,000 newspapers every day, beside an enormous weekly issue, circulating chiefly in the country. The leading morning journals range from 30,000 to 50,000 per day, and on occasions of public excitement sometimes twice as many. There are 10 German, 2 French, 1 Italian, 2 Spanish and 2 Welsh newspapers, one of the German having a very large circulation. The recently originated package express business of the country has its focus in New York, where there are 8 principal and many smaller companies. Beside the freight taken by shippers to their stations, about 800 large wagons are constantly employed in collecting and distributing packages in the city.—New York is preëminently a commercial city, second only in some respects to London. It was founded by the adventurous traders of the Dutch West India company, and has preserved its mercantile character through all vicissitudes. From 1790 to 1800 the population nearly doubled in consequence of the derangement of commerce in Europe, then distracted by wars. Subsequently, until 1812, the rate of progress was rapid, the population rising from 60,000 to nearly 100,000, when the war with Great Britain suspended foreign trade for 8 years, and for that period checked the city's growth. Peace restored prosperity, and in 10 years thereafter 66,000 were added to the census. The completion of the Erie canal in 1825 gave an extraordinary impulse to commerce, and in 10 years the population rose from 166,000 to 268,000, with trade in proportion, soon however to receive a serious if not a salutary check by the

financial crisis of 1837; but the city soon began to recover, and in 5 years added to her census 44,000. Thenceforward the ratio of increase has been great and steady, with equal progress in foreign and domestic commerce, immensely increased by the golden stream from California, and only momentarily stayed by the panic of 1857. At this time New York has a population within her geographical bounds of more than 800,000, and within the suburbs of Brooklyn, Staten island, Jersey City, Hoboken, Mount Vernon, Astoria, Flushing, &c., properly embraced in her commercial circle, not less than 1,800,000, nearly all of whom depend directly upon the business of the city. The chamber of commerce, an influential body of leading merchants and business men, holds monthly meetings to consider questions affecting the interests of trade and commerce generally. It has been in existence since 1768. The imports into New York during the year ending June 30, 1859, were \$244,841,542; exports, \$187,696,187; revenue from customs, \$38,884,212. The imports of New York average 66 per cent. of all that come to the United States, and the exports about 85 per cent. The importation of articles duty free amounted to \$29,184,496, of which the principal items were:

Coffee.....	\$9,054,884	Paintings and statuary.....	\$367,990
Tea.....	7,011,693	Guano.....	143,889
Madder.....	1,866,784	Linseed.....	458,814
Wool.....	2,028,887	Dyewoods.....	492,145
Raw silk.....	1,824,148	Copper.....	743,905
Bags.....	855,966	Gold and silver coins and bullion.....	1,614,101
Tin.....	915,949	Peruvian bark.....	288,747
Seeds and trees.....	892,221		
Reeds.....	812,199		

The importation of dutiable articles amounted to \$189,046,597, of which the principal were:

Beer, ale, and porter.....	\$302,827	Opium.....	\$915,963
Buttons.....	648,789	Paints.....	614,819
Cheese.....	128,770	Paper boxes, cards, maché, writing and blank books.....	584,896
Wholes and materials.....	2,387,899	Printed books, magazines, and papers.....	560,413
Clothing.....	1,095,281	Raw hides and skins.....	8,437,917
Manufactures of cotton.....	19,408,658	Salt.....	897,896
Toys.....	312,982	Silk piece goods.....	20,465,193
Flowers and feathers.....	654,849	Other silks.....	5,664,080
Manufactures of flax.....	8,482,886	Soap.....	858,186
Fruits, mostly dried.....	2,150,456	Soda.....	1,695,914
Furs.....	2,944,845	Spices.....	985,559
Manufactures of glass.....	1,440,009	Brandy.....	2,220,043
Gems.....	840,800	Pure spirits.....	1,156,071
Jewelry.....	411,181	Brown sugar.....	19,192,466
Gums.....	880,980	Tin, plate and sheet.....	4,215,763
Hair and hair goods.....	989,817	Cigars.....	2,201,186
Hats and bonnets.....	1,047,549	Other tobacco and snuff.....	1,482,613
Hemp and its manufactures.....	400,780	China ware.....	1,886,676
India rubber.....	897,111	Champagne.....	1,207,847
Indigo.....	678,158	Other wines.....	1,188,487
Iron and steel.....	9,948,893	Mahogany.....	218,957
Lutes.....	998,788	Rosewood.....	110,518
Laces of all kinds.....	8,594,210	Woolen piece goods.....	10,418,886
Lead.....	2,312,989	Worsted piece goods.....	11,207,149
Gloves of leather.....	1,280,760	Shawls of wool.....	2,545,808
Leather.....	4,572,482	Blankets.....	1,251,269
Liquorice.....	495,008	Carpeting.....	1,774,639
Mating.....	288,166	Hosiery.....	631,544
Molasses.....	1,687,540	Woolen yarn.....	856,285
Musical instruments.....	279,885	Other goods of wool.....	1,917,418
Nuts.....	889,845	Zinc.....	1,335,905
Oils of all kinds.....	1,381,287		

The principal exports were as follows:

Asbes.....	\$465,814	Manufactured tobacco.....	\$1,311,506
Beef.....	1,561,884	Cotton goods.....	4,414,710
Biscuit.....	318,979	Manufactures of wood.....	594,094
Boards and lumber.....	1,344,979	Bark and dyewoods.....	291,589
Books.....	114,400	Oil cake.....	811,581
Butter.....	490,097	Sperm oil.....	1,705,895
Candles.....	298,240	Whale oil.....	262,276
Cordage.....	208,796	Whalebone.....	1,178,588
Carriages.....	438,678	Paints.....	111,901
Cheese.....	500,279	Paper.....	149,400
Clover seed.....	481,160	Pork.....	1,747,687
Coal.....	207,863	Potatoes.....	114,866
Copper and brass.....	852,684	Rice.....	865,508
Corn and meal.....	742,949	Rosin and turpentine.....	1,828,016
Cotton, raw.....	8,912,811	Rye, oats, and peas.....	869,983
Drugs.....	599,498	Skins and furs.....	1,118,886
Fish.....	247,006	Soap.....	173,878
Gold and silver coin.....	19,213,558	Pure spirits.....	487,611
Bullion.....	24,412,987	Spirits turpentine.....	1,694,501
Gunpowder.....	112,090	Tallow.....	251,635
Hams and bacon.....	646,993	Tobacco.....	1,455,797
House furniture.....	425,894	Wearing apparel.....	156,038
Iron and nails.....	2,718,176	Wheat.....	1,886,112
Lard.....	1,206,835	Wheat flour.....	5,804,238
Leather.....	242,985		
Boots and shoes.....	217,584		

The commercial growth of New York, compared with that of the whole country, will be seen by the following tables:

IMPORTS AT DIFFERENT PERIODS.

Years.	New York.	Other ports.	Per cent. for N. York.
1821.....	\$38,029,000	\$38,956,000	37.75
1831.....	57,077,900	45,114,000	55.81
1841.....	75,718,000	59,288,000	59.18
1851.....	141,546,000	74,478,000	65.46
1855-'56.....	210,160,454	104,479,468	66.79
1856-'57.....	286,498,455	124,896,656	65.53
1857-'58.....	178,475,736	104,187,414	68.15
1858-'59.....	229,181,849	109,596,751	67.65

EXPORTS FOR FOUR YEARS.

Years.	New York.	Other ports.	Per cent. for N. York.
1855-'56.....	\$111,119,500	\$307,868,408	26.48
1856-'57.....	124,808,298	228,157,284	37.14
1857-'58.....	108,840,994	216,808,496	33.87
1858-'59.....	117,589,295	239,249,867	32.94

Before 1855 about one half the imports at this port consisted of dry goods; since that time the rapid increase has been chiefly in general merchandise. The following is a condensed view of the course of trade for the first 9 months of 1858, 1859, and 1860:

EXPORTS.

Character.	1858.	1859.	1860.
Merchandise.....	\$45,648,800	\$49,246,500	\$69,647,100
Specie.....	20,602,900	67,929,500	89,857,200
Total, 9 months.....	\$66,251,700	\$117,176,000	\$159,504,300

IMPORTS.

Character.	1858.	1859.	1860.
Dry goods.....	\$47,707,100	\$38,488,000	\$55,091,900
Merchandise.....	67,618,000	104,256,900	92,718,000
Total.....	\$115,325,100	\$142,744,900	\$147,809,900
Duties.....	20,604,478	81,514,949	80,873,751

The principal articles of domestic product exported were 1,269,687 bbls. flour, 6,669,566 bush. wheat, 1,889,821 bush. corn, 171,881 bbls. beef and pork, 1,422,491 galls. oil, and

large quantities of bacon, lard, cheese, and butter. More than $\frac{3}{4}$ of the customs revenue of the United States is collected at New York, where from 700 to 800 revenue officers and clerks are employed.—During the financial year 1858-'9, there were cleared from the port of New York 1,911 American vessels, tonnage 925,528, with 80,519 men, and 1,175 foreign, tonnage 550,751, with 22,856 men; total cleared, 3,086 vessels, 1,476,279 tons, and 82,875 men. In the same period there were entered 2,659 American vessels, tonnage 1,820,296, with 40,011 men, and 1,245 foreign, tonnage 569,854, with 23,628 men; total entered, 3,902 vessels, 1,890,144 tons, and 63,634 men. Of the clearances, 266 were for England, 619 for British North America, 296 for British West Indies, 508 for Cuba, 108 for New Granada, and 40 for China. Of the entries, 519 were from England, 404 from British North America, 817 from British West Indies, 169 from France, 891 from Cuba, 209 from Porto Rico, 167 from Brazil, and 55 from China. The tonnage belonging to New York is as follows: registered permanent, 639,021; registered temporary, 205,411; enrolled and licensed, 586,506; under 20 tons, coasting, 13,207; steam registered 70,898, steam enrolled 120,498; coasting trade, 586,506; aggregate tonnage of the city, 1,444,361, exceeding that of any other port that ever existed. There is no actual record of the coasting trade of New York, but it is certain that within the past year there were not fewer than 9,500 arrivals coastwise and an equal number of clearances. By the census of 1855 there were 25 ship building establishments in and near the city, some of them the most extensive in the country. In 1858 there were built within the New York collection district 7 ships and barks, 2 brigs, 21 schooners, 84 sloops, and 26 steamers—in all 140 vessels, of 25,854 tons. In the year ending Sept. 30, 1860, there were launched or building in the New York and Long Island ship yards, 28 steamers (of which 8 were of iron), measuring 20,468 tons, and valued at \$3,500,000; also 1 ship, 2 barks, 8 brigs, 2 schooners, 4 pilot and 7 ferry boats, registering 5,781 tons, and valued at \$762,000.—The internal trade of New York by water passes north and west over the Hudson river to the Delaware and Hudson, Erie, and Champlain canals, by steamboats, barges, canal boats, and sailing vessels; eastward over Long Island sound in steam and sailing craft of larger tonnage; and southward in coasting vessels. The completion of the Erie canal in 1825 made New York the maritime outlet for the surplus produce of the great West. Previous to that time western produce went down the Susquehanna to Baltimore or the Schuylkill to Philadelphia; and, except in the region tributary to the Hudson river and Long Island sound, New York had no domestic commerce. By the Erie canal she was placed in easy communication with a wonderfully fertile region of 1,000,000 square miles, with 2,500 miles

of navigable waters, and a population then of less than 500,000, now increased to 9,000,000 or 10,000,000. In 1858 the Erie canal brought to tide water 1,496,687 tons of freight, including wheat and flour equal to 3,568,901 bbls. of the latter, nearly all of which came to New York city. The water trade eastward is mostly the carrying away of raw materials and the return of manufactured articles. The principal railroads of the state, terminating here, in 1859 carried 4,243,000 passengers, and 1,252,881 tons of freight, of which 802,128 was animal and 189,960 tons vegetable food. The New York central railroad in the same time carried 2,124,489 passengers and 765,407 tons—172,076 animal and 301,507 vegetable food—nearly all arriving at the city. Beside these, there are 4 railroads in New Jersey carrying at least 2,000,000 passengers and a proportionate amount of freight. During the first 9 months of 1860, there came to New York, by railroad and canal, 2,398,819 bbls. flour, 8,677,552 bush. wheat, 10,823,177 bush. corn, 97,142 bush. rye, 146,833 bush. barley, 2,807,211 bush. oats, 89,863 tierces and bbls. beef, 91,666 bbls. pork, 53,253 packages bacon, 97,786 packages lard, and 827,777 packages cheese.—There are 54 banks doing business in the city, of which the bank of the state of New York, founded in 1784, is the oldest. The condition of these banks, as officially declared Sept. 30, 1860, was as follows:

Liabilities.		Resources.	
Capital.....	\$69,290,475	Loans.....	\$120,271,555
Net profits.....	7,559,839	Stocks, real estate, &c.....	19,893,478
Circulation.....	9,186,897	Due from banks	7,368,063
Due other banks	21,271,956	Cash items.....	22,418,015
Deposits.....	81,388,120	Specie.....	20,116,447
Miscellaneous...	1,029,961	Overdrafts.....	54,175

Total.....\$189,621,728 Total.....\$189,621,728
In 1858 a clearing house was established, at which all banks are required to settle their balances with each other in specie every morning, and publish a weekly statement of their condition. For the year ending Sept. 30, 1859, the clearing house exchanges were \$6,448,005,956, or \$20,867,838.19 per day. The average daily liability of the banks in 1859 was \$95,124,728, and the amount of specie was 28 per cent. There are 10 marine insurance companies, with an aggregate capital of \$8,000,000; earnings in 1859, over \$12,000,000; losses and expenses, \$8,000,000; amount insured, \$740,000,000. Marine losses for the year on ships, \$16,702,752; on cargoes, \$20,558,420; total, \$37,256,172. For fire insurance there are 90 companies, the oldest dating from 1787; gross capital, \$18,000,000; risks, over \$700,000,000. Eight new companies were organized in 1859. In 1858 the capital of the city companies was \$16,696,010; surplus, \$5,282,493; premiums, \$5,559,830; gross income, \$6,962,216; losses, \$1,904,044; dividends, \$2,484,976; taxes, 272,128; gross expenditures, \$6,079,804; outstanding liabilities, \$2,445,442. The transactions in 1859 of 14 life insurance companies whose business is mainly in this city, were as follows: policies at commencement of the year, 45,092;

amount insured, \$125,806,078; premiums for a year, \$4,588,662. The claims paid in 1858 were \$1,260,494; expenses, \$591,876; assets, \$18,946,322. There are 18 savings banks, holding \$43,410,083 from 196,979 depositors; increase of deposits in one year, \$8,000,000. Of the 8 largest savings banks, the Bowery has \$9,573,400 on deposit, Bleecker street \$9,544,479, and Seamen's \$8,188,715. The six-penny savings bank (for children) has \$146,294 from 8,869 depositors. Average to each depositor in all the banks, \$208.91; deposited in 1859, \$30,808,888; withdrawn, \$23,808,109; received for interest, \$3,049,924. Three more banks for savings were incorporated in the winter of 1860. In addition to this accumulated capital, there is \$74,000,000 of individual deposits in banks of discount, \$17,000,000 in life insurance companies, and \$10,000,000 in trust companies, making \$144,500,000 of cash laid up by the working classes of the city.

—The New York post office is by far the most important in the country. During the year ending Sept. 30, 1860, the receipts were \$904,121.49, of which \$673,234.09 was for stamps and stamped envelopes; 15,507,654 letters were mailed, exclusive of those coming from other offices to be remailed; 18,252,584 letters were received for delivery in the city; 8,416,774 letters were remailed to other offices; 4,681,987 circulars were mailed; 4,818,949 mail letters, 1,271,640 city letters, and 618,518 newspapers were delivered by carriers; 8,516,567 letters and 860,318 newspapers for the mails, and 678,494 city letters, were collected from the street boxes and stations; 172,821 registered letters were sent and received; 570,407 letters were sent to and 838,086 were received from California; 2,942,449 foreign letters were sent and 2,486,535 received; 270,602 letters were sent to the dead-letter office; 200 steamships left with mails for foreign ports, and 201 arrived, in the year. During the quarter ending Sept. 30, 46,264 locked mail letter bags were sent out, and 43,813 received; and 43,787 bags of newspapers and other printed matter were sent, and 40,888 received. The number of daily mails sent out is: north, 1,641; east, 1,049; west, 950; south, 1,125. There are 574 street letter boxes, 28 collectors, and 89 carriers; 228 clerks in the general office, and 14 at the 4 stations; 4,262 boxes are rented at the general office.—Henry Hudson discovered Manhattan island, Sept. 12, 1609. A temporary settlement was made by the Dutch in 1612, and a permanent one in 1623, when a small fort was built. The same year the first white child was born in the colony, Sarah Rapelje. Peter Minuits, the first Dutch governor, arrived in 1624, and purchased Manhattan island of the Indians for \$24. A new fort was begun in 1633, on the present site of the Battery. Wouter van Twiller became governor in 1638, and William Kieft in 1638. Tobacco was cultivated and slavery introduced before 1638. In 1644 a city hall

was built in Coenties slip, and in 1647 Gov. Stuyvesant arrived; he was the last of the Dutch governors, ruling for 17 years. In 1653 a wall was built across the island at Wall street, for defence against Indians and the expected troops of Cromwell. In 1656 the city had 120 houses and 1,000 inhabitants. Wharfs were built in 1658, and a windmill in 1662. Charles II., having come to the English throne, assumed the Dutch occupancy in North America to be a usurpation, and on March 12, 1664, granted the entire territory to his brother the duke of York. A small fleet arrived in August, and the city surrendered without resistance, Col. Richard Nicolls assuming the office of governor. The name (New Amsterdam) was changed to New York, and an English form of government was established, which lasted 9 years; when, in July, 1673, the Dutch recaptured the city, named it New Orange, made Anthony Colve governor, and drove out the English. Their triumph was short, for by the peace between England and the states-general, the city was restored to the British crown, and once more called New York, and the Dutch power was finally ended, Nov. 10, 1674. For the remainder of the 17th century, the progress of the city was rapid. The old Dutch charter was replaced in 1686 by a more particular and liberal grant from the crown known as the Dongan charter. The only untoward event of the period was the unsuccessful rebellion of Jacob Leisler in 1689. (See LEISLER.) At the close of the century, New York had about 750 dwellings, and 4,500 white and 750 black inhabitants. The first Trinity church was built in 1696. In 1702 a pestilent fever was brought from St. Thomas, from which nearly 600 persons died, or about 1 in 10 of the population. Some Huguenot families arrived, and, in spite of the state, freedom of religion was practically secured. Wall and other streets were paved, watchmen employed, and in 1711 a regular slave market was established. In 1719 the first Presbyterian church was built. The "New York Gazette," the fifth newspaper in the colonies, was begun in 1725, and Zenger's "Weekly Journal" in 1733. Stages ran to Boston in 1732, being 14 days on the journey, and infectious fever prevailed with great fatality. In 1735 occurred the first attack upon the freedom of speech. By the death of Gov. Montgomerie, the duties of the office devolved until the appointment of a new governor upon Rip van Dam, the oldest member of the council. Van Dam officiated a year, when Gov. Cosby arrived, and claimed half the fees collected by Van Dam. A suit followed; and by the suppression of almost all the forms of justice, Van Dam was beaten. The people took up the quarrel, which was really the first step of separation or distinction between the people of Great Britain and those of the colony; lampoons, satires, and libellous ballads were rife, and the two newspapers joined in the controversy—the "Gazette"

supporting Cosby and the "Journal" violently opposing him. The council directed certain copies of the "Journal" to be burned, and ordered the mayor and magistrates to attend the ceremony; they refused, and the general assembly sympathized with them. Zenger was imprisoned for libel, and Cosby's party strained every nerve to convict him, going so far as to dismiss from the bar eminent lawyers who took his part. Against this, and in the face of the most outrageous rulings of the court, a jury declared Zenger not guilty. The year 1741 was remarkable for fire, pestilence, and insurrection; the Dutch church in the fort and a part of the fort itself were burned; yellow fever prevailed to a considerable extent; and the imaginary negro plot occurred. This so called plot, which was never proved, created the greatest alarm; the fire in the fort was charged to the negroes; arrests were made, and upon the testimony of a single servant girl a number were executed. The most important victim was John Ury, a Roman Catholic priest, doubtless perfectly innocent, who was hanged in August. Within 6 months 154 negroes and 20 whites were imprisoned, of whom 55 were convicted, 78 confessed, 18 negroes were burned at the stake, 20 were hanged, 78 were transported, and the remainder were discharged. The evidence in any of the cases would now be considered worthless. In 1743 a pestilence carried off 217 persons, chiefly from marshy localities. In 1750 a theatre was established. In 1755 St. Paul's church was built. In that year began the stamp act excitement, and a colonial congress assembled in New York; figures of the governor and the devil holding the stamp act were burned in public. In 1765 the sons of liberty were organized to oppose the stamp act, a committee was appointed to correspond with other colonies, and the governor was burned in effigy. In 1770 a meeting of 8,000 citizens was held, who resolved not to submit to oppression, and a slight collision with the troops occurred; a committee of 100 was appointed to resist the importation of obnoxious goods, subsequently restricted to tea only; the statue of George III in the Bowling Green was destroyed, and a marble statue erected to Pitt, for his exertions in the repeal of the stamp act. In 1772, Pitt having become Lord Chatham and changed his course, this statue was mutilated; it was removed in 1788, and the torso is now at a hotel in West Broadway. In 1778 the vigilance committee agreed to resist the landing of tea, and in 1774 a ship thus laden was stopped at Sandy Hook and sent back to England, 18 chests secretly landed being destroyed. The same year, at a great meeting on the common, strong revolutionary resolutions were passed. On April 3, 1775, the colonial assembly finally adjourned; on July 25 delegates were elected to the continental congress; and on Aug. 28 congress ordered Capt. Lamb to remove the cannon from the city forts to the highlands;

resistance was offered from the Asia man-of-war, but 21 pieces, all that were mounted, were secured. On Aug. 26, 1776, by the result of the battle of Long island, the city fell into the hands of the British, and so remained until the close of the war. On Sept. 21, 1776, a fire destroyed 498 houses, all the west side of Broadway from Whitehall to Barclay street ($\frac{1}{4}$ of the city) being laid in ashes. On Aug. 7, 1778, another fire destroyed 800 buildings around Cruger's wharf, on the East river. The winter of 1780 was very cold; ice covered the bay, and heavy teams and artillery crossed to Paulus Hook (Jersey City). On Nov. 25, 1788, the British finally evacuated the city, and Gen. Washington marched in; the day is still annually celebrated under the name of evacuation day. During the war the British had nearly destroyed all the churches except the Episcopal, making prisons, riding schools, and stables of them; the college and schools had been closed. In 1785 the first federal congress organized at the city hall on the corner of Wall and Nassau streets; in the next year the first Roman Catholic church (St. Peter's, Barclay street) was built, and the first divorce suit was brought. The adoption of the federal constitution was grandly celebrated in 1788; and the inauguration of President Washington took place at the city hall, April 30, 1789. In 1788 a serious riot occurred at the hospital, in consequence of the careless exposure of dissected bodies. The doctors were mobbed, their houses invaded, some of them were compelled to fly from the city, and others took refuge in the gaol. A census in 1790 showed a population of 29,906. In 1791 yellow fever carried off 200 victims. The city, now just reaching the lower corner of the park, began to extend along the Boston road (Bowery) and Broadway; an almshouse was built in the park, and had 622 inmates in 1795. The park theatre was begun this year and opened in 1789. In the latter year 2,086 persons died in 8 months from yellow fever, which returned at intervals until 1805, but with diminishing virulence. The Manhattan company, for supplying the city with water, was chartered in 1799. On Sept. 20, 1808, the corner stone of the city hall was laid by Mayor Livingston; the hall was finished in 1812, when the old one in Wall street was sold. In the winter of 1804, 40 stores in Wall and Front streets were burned. The free school society, the germ of the present board of education, was incorporated in 1805. The city had now 78,770 inhabitants, and streets were extending across the Canal street marsh, while the collect or swamp where the city prison now stands was being filled up. The spread of population was stimulated by the yellow fever, which drove a third of the people from their dwellings below the park to the woods and fields north of the fresh water. In 1807 Robert Fulton navigated the first steamboat from near New York to Albany. In 1812 Fulton leased the Brooklyn ferries

for \$4,000 a year, to run by steam. A great fire in Chatham street in 1811 consumed nearly 100 houses. The war of 1812 with Great Britain temporarily checked the city's growth, the census in 1814 showing a decrease of 2,312 from 1810. In Aug. 1812, experiments with gas lights were made in the park. Fulton's steam frigate was launched in Oct. 1814. In 1821 the survey and laying out of the island north of Houston street was completed after 10 years' labor. In the winter of this year the Hudson river was frozen over for the first time in 41 years. Yellow fever reappeared in 1822, occasioning a great panic; the city south of the park was fenced off and nearly deserted, families, merchants, banks, and even the city government removing to Greenwich (now the 9th ward) and upper Broadway; yet the mortality was not comparatively great, fewer than 200 persons being victims. This panic materially improved property north of Canal street, and correspondingly expanded the city. In 1823 interments south of Canal street were forbidden, Washington square was regulated, and a gas company organized—gas being first generally used two years later. The city now had 12 wards, and was growing at the rate of 1,000 to 1,500 houses per year—a growth occasioned by the completion of the Erie canal, the first boat from which arrived Nov. 4, 1825. The canal celebration was the grandest affair ever known in the country. In the next decade New York received some severe blows from pestilence, fire, and financial disaster. The cholera appeared in 1832, carrying off 8,518 persons, and again in 1834, taking 971. On Dec. 16, 1835, the most disastrous fire known to the city swept the 1st ward east of Broadway and below Wall street, destroying 648 of the most valuable stores, the merchants' exchange and the South Dutch church, and property valued at more than \$18,000,000. With almost miraculous energy the city was rising from these ashes, when the financial explosion of 1837 came, with suspension of specie payments, failures, and bankruptcy throughout the country. Even this, however, but momentarily checked the progress of the city, her population increasing from 202,600 in 1830 to 312,700 in 1840. In 1842 the Orono water was introduced. On July 19, 1845, a great fire occurred between Broadway, Exchange place, Broad, and Stone streets, destroying over \$5,000,000 worth of property. Within 40 years theatres have been burned as follows: the Park in 1821 and 1848; the Bowery in 1828, 1836, 1838, and 1845; the Mount Pitt circus in 1828; La Fayette in 1829; the national in 1839 and 1841; Niblo's in 1846; the Franklin in 1849. In 1849, by legislative act and vote of the people, radical changes were made in the city charter, the selection of leading officers being opened to popular suffrage, and the police partially (since wholly) taken from the control of the mayor. The most serious popular disturbance of recent times was the Astor place riot in May, 1849, grow-

ing out of the assumed hostility of two prominent actors. (See MACREADY, WILLIAM C.) Cholera came again in the summer of 1849 and carried off 5,071 persons; and lastly in 1854, when 874 died. The first city railroad was built in 1852, in anticipation of the projected industrial exhibition, which opened with great ceremony (the president of the United States officiating) July 14, 1853, in a magnificent crystal palace in the form of a Greek cross, built of iron and glass, 365½ feet in diameter each way, with galleries, and a dome 128 feet high and 100 wide, the flooring covering 5½ acres. This building was burned in 1858. In 1857 occurred another financial panic, but its consequences were not extensively disastrous. In the same year the radical change in the control of the police made by the legislature, and the resistance to the act by Mayor Wood, resulted in popular disturbances in June and July. The first serious trouble was on June 9, when a conflict occurred for the possession of the street commissioner's office—the governor having appointed a new head, and the mayor refusing to deliver the keys. An order was issued for the arrest of the mayor, and a detachment of the new or metropolitan police went with the officer to serve it. They were resisted by the old or municipal police, who adhered to the mayor, and a savage fight ensued on the steps of the city hall; many were hurt, but none killed. The 7th regiment chanced to be on parade for a visit to Boston, and were summoned to the city hall. The governor of the state came to the city, but the whole matter was soon transferred to the courts in the form of a suit for possession of the disputed office. There was no further disturbance until July 3, when the decision of the court of appeals sustaining the new police law was announced. This law had been violently denounced by the mayor, and the more turbulent and dangerous of the people openly resisted it. Under pretence of obedience to the court of last resort, the mayor disbanded his police on the eve of the national celebration. On the 4th the usual license of a holiday led to various disturbances, resulting finally in a serious conflict known as the "dead rabbit riot." The dead rabbits were a faction of the rowdy and vagabond boys and young men of the Five Points, mostly composed of thieves and convicts. On the night of the 8d they attacked the police patrolmen in the Bowery, but were driven off by another faction known as Bowery boys. The next day an assault was made upon the police in Jackson street, and in the evening there was a series of fights in the Five Points, where even the women threw bricks, stones, pots, and kettles at the police from the tops of the houses. The Bowery boys mingled in the fight also, and for hours there was a running contest over most of the 6th ward. There was some pistol firing, and the mob got possession of a howitzer, but did not use it. Order was restored by calling out a detachment of mili-

tary, who marched to and fro over the ground, where they found piles of bricks and stones, ready for use by the mob. Some of the police were badly bruised, and one died from his wounds; 11 persons in all lost their lives through this riot.—The original charter of New York city was granted by James II. in 1686, amended by Queen Anne in 1708, further enlarged by George II. in 1730, confirmed by the general assembly of the province in 1732, and specially affirmed after the revolution by the state legislature. This charter was of the most liberal nature; it made New York practically a free government, established an elective council, and gave unusual privileges to the people. The most important property grants were the exclusive possession and control of the waters to low water mark on all the shores opposite Manhattan island, with the ownership of the ferries for all time, and the proprietorship of all waste and unoccupied lands on the island. The "mayor, aldermen, and commonalty" were made a perpetual corporation; municipal officers were created; an annual election was ordered, at which all freeholders and those made freemen by the act of the city might vote; full power was conferred to make roads, bridges, and ferries, establish markets, regulate the sale of merchandises, make free citizens, hold courts and administer justice, erect and own wharfs, grant licenses for all manner of retail trade, and do all necessary acts for the establishment and maintenance of the government. The mayor was appointed by the provincial governor and council until the revolution; by the state governor and council of appointment until 1821; by the common council until 1834; and thenceforward by the people in general election. No direct changes were made in this charter for 100 years; but much of the judicial power had been transferred to regular courts, and the number of members of the common council had increased with the growth of the city. In 1839 the people in city convention prepared, and the legislature adopted, the amended charter of 1830. It divided the common council into two boards of concurrent powers, gave the mayor a veto, and provided against extravagance by prohibiting the drawing of money from the treasury except upon previous specific appropriations. The next amendments were made in 1849, when the government was divided into 7 departments, the head of each being elected by the people; the mayor's term was extended to two years; and further checks were put upon hasty or wasteful expenditures by requiring previous publicity and prohibiting members of the common council from being interested in city work. In 1853 the board of assistant aldermen was changed to a board of 60 councilmen, the term of aldermen extended to two years, and city works and property were ordered to be let or sold by contract or at auction; the aldermen were displaced from the court of sessions and the oyer and terminer

and the appointment of policemen (up to this time made practically by the aldermen) was confided to the mayor, city judge, and recorder. The last and most important changes were made by the amendments of 1857; the city was redistricted for aldermen, reducing the number from 22 to 17; the 60 councilmen were reduced to 24; the aldermen were no longer supervisors, a new county board being created; the mayor and common council were entirely dissevered from the police; the salaries of aldermen and councilmen were abolished (but have since been restored), and their powers were materially restricted, particularly in the license for selling liquors, that duty going to a special commission; the mode of choosing heads of departments was changed in several instances from election to appointment by the mayor and aldermen; some departments were abolished; and still further safeguards were enacted against reckless expense, by requiring a nearly unanimous vote to exceed certain specified appropriations, and making malfeasance on the part of a member of the common council an indictable offence. But with all these changes, the charter of 1730, known as the "Montgomery charter," is recognized as the fountain head of city government, and upon its liberal provisions rest the vast public and private interests of the municipality.

NEW ZEALAND (so called by its Dutch discoverer Tasman, in honor of Zealand in the Netherlands), a British colony consisting of 3 islands in the South Pacific ocean, called respectively the North island, the Middle island, and the South or Stewart's island, stretching from lat. 34° 15' to 47° 30' S., and between long. 166° and 179° E., and about 1,200 m. S. E. from Australia; pop. about 120,000, of whom 56,000 are aborigines. The North island is 500 m. long and of very irregular shape, varying in breadth from 5 to 300 m. The Middle island is 550 m. long, with an average breadth of 110 m. The South island is triangular in shape, and measures about 80 m. on each side. The North island contains 40,000 sq. m., the Middle island 60,000, and the South island 1,500; total area, 101,500 sq. m. The three islands in shape, like Italy, resemble a boot, the toe of which is toward the N.; and they are nearly equal in size to that peninsula, exclusive of the islands of Sicily and Sardinia.—The North island is separated from the Middle island by Cook's strait, which at its narrowest part is 18 m. wide; and the Middle is separated from the South island by Foveaux's strait, which is 15 m. wide. The coast line of the whole group is 8,120 m. in length, of which about one half belongs to the North island, whose shores abound in indentations. The best harbors of this island are in the northern district, between North Cape and Cape Colville, in which are found the magnificent ports of Mongonui, Wanganui, Auckland, and the Bay of Islands. South of Cape Colville, on the E. side, for the space of 200 m., there are only two safe anchorages,

Mercury bay and Tauranga, the former of which does not admit large vessels. On the remainder of the E. coast, for a distance of 400 m., there is no safe harbor except the excellent one at Wellington at the S. end of the island. On the W. coast of the North island the principal harbors are Manukua, Kaipara, and Hokianga, which are spacious and secure, but obstructed by sand bars at the entrances. At the N. extremity of the Middle island are many extensive sounds and harbors with deep water; but along the whole of the E. coast, a distance of 500 m., the only ports are Akaroa, Victoria, and Otago. On the S. and S. W. sides of this island harbors are numerous and excellent; and higher up on the W. side is Jackson's bay, a safe anchorage. From Jackson's bay northward, a distance of 800 m., the rest of the W. coast of the Middle island is open and exposed. In the South island there are several safe harbors. The tide on the E. coast of the group rises to the average height of 8 feet, and on the W. coast 10 feet.—The centre of the North island is occupied by lofty mountains, which send off spurs in various directions to the sea coast, and are covered from their bases nearly to their summits with primeval forests. The highest mountain of the central range is Ruapahu, which is 9,000 feet high, and rises into the region of perpetual snow; one of its peaks, Tongariro, is an active volcano, 6,000 feet high. At the S. W. extremity of the island is Mt. Egmont, a volcano, 8,270 feet high; it is a perfect cone in shape, and always capped with snow. Three lines of volcanic craters with high cones stretch across the island, and in the centre of the great bay of Plenty on the N. coast is an active volcano called Wakavi or White island, which is 8 m. in circumference and 860 feet high. The Middle island is traversed by a mountain range which runs from the N. to the S. W. extremity, and in some places reaches an elevation of 13,000 feet, far beyond the snow line; its highest peak is called by the English Mt. Cook. The highest portion of this range is known as the Southern Alps. Toward both the E. and W. coasts this range is abrupt and precipitous. On the E. broad and fertile plains, and on the W. a narrow strip of land, lie between it and the sea. In the centre of the island are extensive table-lands. There are no volcanoes, active or extinct, in the Middle island. The South island is mountainous, but the highest summits do not exceed 8,000 feet in elevation.—The North island abounds in rivers and inlets of the sea, which give easy access to the most inland districts. The largest river is the Waikato, which rises in the Taupo lake near the centre of the island, and running N. 200 m. reaches the sea on the W. coast. Several rivers of considerable size flow from the central mountains of the Middle island across the great eastern plain to the sea. Like all the rivers of New Zealand, they are subject to great and sudden floods from the melting of the moun-

tain snows. The interior of the North island abounds in lakes, one of which, Lake Taupo, is 80 m. long and 20 broad; another, Rotomahana, is in parts boiling hot. There are several extensive lakes in the centre of the Middle island, one of which, called Te Wai Pounamu, is said to be of a green color and bordered by greenstone rocks.—In the North island the rocks are primary, metamorphic, volcanic, trappean, and sedimentary. The mountains are chiefly composed of lower slate rocks, intersected with basaltic veins, scoriae, slate, primary sandstone, and limestone. The rocks contain sulphur, alum, manganese, obsidian, iron, copper, silver, and gold. In the limestone districts are extensive caverns formed by the action of water. Hot and cold springs, impregnated with sulphur, iron, and silicious matter, are found in every district. In the Middle island the lower rocks are clay and metamorphic schists, intersected by dikes of greenstone, with compact and amygdaloidal basalt. Granite has not been found. The plains are composed of clayey loam, and beds of coal and lignite are known to exist. Earthquakes are very frequent in New Zealand. At Nelson 55 shocks were registered between 1848 and 1854, and at Wellington there were 24 shocks in 1846. Cook's strait is the centre of the earthquake region. The shocks are not violent, and with slightly built houses are not much dreaded. Throughout the group there appears to be a gradual rising of the land, so that in Cook's strait rocks have appeared where none were visible when the country was first discovered, and at Port Nicholson the land has risen 5 feet since 1848. "New Zealand," says Dr. Thomson, "is an admirable geological school; there travellers may see the form of Vesuvius, the dome-shaped summits of Auvergne, the elevated craters of the Caracas, and the geysers of Iceland. Taupo, Tongariro, Rotomahana, Rotorua, and White island are almost unrivalled geological curiosities. Above the entombed village of Te Rapa, on the border of the Taupo lake, basaltic rocks may be seen in the process of conversion into soft clay by heat and chemical action; where the Tongariro river falls into the lake, travellers may observe how rapidly pumice stone and other deposits are lessening the size of this inland sea. Grand and beautiful geysers, ejecting water 2° above the boiling point of pure water, and holding various silicates in solution, are found around the lakes of Rotomahana and Rotorua. This water on cooling incrusts every substance it comes in contact with, and birds thrown into it are brought out like pieces of flint."—The flora of New Zealand is as remarkable as its geology. It is characterized by the comparatively large number of trees and ferns, the paucity of herbaceous plants, and the almost total want of annuals. There are 120 species of indigenous trees, and more than 2,000 species of plants have already been discovered of which 507 species of flowering plants

are peculiar to the country. The *conifers* are the most conspicuous natural order, although with comparatively few species. Almost all the trees of New Zealand are evergreens, and the change of seasons consequently makes little difference in the appearance of the forests. The most remarkable tree is the *kauri* pine, which is found only in the N. part of the North island. It grows to great size, often to a circumference of 40 feet, and rising to the height of 90 feet without a branch. From the lightness and toughness of the stem it is well adapted for masts, for which it is in great demand. It produces a gum which has been sold in England for \$400 a ton; but the fresh gum is worthless, and only that is of value which is found buried in the earth on the site of ancient forests. The *totara* pine equals the *kauri* in size and commercial value; and the *puriri*, a tree of the same botanical order as the teak, rivals the English oak in hardness, and has a girth of 30 feet. One palm tree, the *areca sapida*, grows in New Zealand. The abundant fern roots of the country formerly supplied the aborigines with food, as did also the tender shoots of the palm. From the poisonous *tutu* berries they expressed a wholesome and refreshing drink. The trunks of the *kauri* and *totara* pines served for canoes, and the tough *titi* tree furnished paddles and spears. But the main reliance of the natives was on the flax plant, which was used for building and thatching huts, and of which they made sails, nets, fishing tackle, plates, ropes, baskets, medicine, and the chief part of their clothing.—Thirteen species of sea mammalia are found on the coasts, viz., 8 whales, 3 dolphins, and 3 seals. Dogs and rats were the only native quadrupeds when the islands were first visited by Europeans. The native rats have been nearly destroyed by the Norway rat, introduced by the English settlers; and the native dogs, which were formerly used for food, are now extinct, no care having been taken to preserve them after the introduction of the pig, which took their place on the tables of the natives. New Zealand has 83 species of birds, most of which have plumage of dull colors. Of the falcon family there are two species, one called *kahu*, about the size of a pigeon; the other, called *karewarewa*, is an active and daring sparrow hawk. There is only one species of owl, which the natives call *kou-kou* or *ru-ru*, while the settlers call it "more pork," because its cry resembles those words. One of the most celebrated birds among the natives is the *hūia*, which has the color and is about the size of the blackbird. It has 4 long tail feathers tipped with white, which are worn by the natives as ornaments for the head. The *tui*, a dark-colored bird of the honey-sucker family, is called the parson by the Europeans from two snow-white feathers which hang under the chin like a clergyman's bands; it is also called the mocking bird from its powers of imitation. It is one of the most common birds in the country. Another honey-

sucker, called *kokoromaka* by the natives and bell bird by the settlers, is about the size of a sparrow, with a long beak, and is a famous songster. There is one species of crow, a small, timid, and thievish bird. The parrot family is abundant, and has 5 species, 8 of which are small green birds with different colored heads. The *kaka* is a large brown parrot, great numbers of which assemble at sunrise and sunset on berry-bearing trees, uttering discordant screams, which among the natives serve as signals for the beginning and end of the day's labor. "The *kaka* has cried" is synonymous with "The cock has crowed," or "It is time to get up." The *kakapo*, or night parrot, is a very remarkable species, about the size of a common fowl. There is one species of pigeon, a large, stupid bird, very numerous and much used for food. The most peculiar birds of New Zealand are 3 species of the *struthionidae* or runner family, which are called *kiwi* by the natives and *apteryx* by naturalists, the largest being about the size of a turkey, and the smallest 18 inches long. These wingless and tailless birds are nocturnal and burrowing in their habits, and have hair-like feathers and long beaks for searching out worms in mud and water. Allied to these strange creatures was the gigantic *dinornis*, now probably extinct, which reached the height of 14 or 16 feet. (See *DINORNIS*.) The natives called these monsters *moas*, and from their traditional descriptions the bird seems to have resembled in shape and appearance a Cochin China fowl. It is thought by some of the settlers that specimens of these birds yet live in the interior of the Middle island, though none have been seen since 1650. There are no serpents in New Zealand, and toads and frogs were unknown to the natives, though since 1852 a few small specimens have been found by the English settlers. Six species of small and harmless lizards have been found, and are held in terror by the natives from a superstitious feeling that the spirits of their ancestors inhabit them. The bravest warrior, it is said, will tremble at the mention of their name, which is in the native tongue *ngarara*. More than 100 species of fish are found on the coasts, of which the largest peculiar to the islands is the *hapuku*, which is often caught exceeding 100 lbs. in weight. In the rivers and lakes eels are found weighing 50 lbs., and the lakes abound with *inanga*, a small, delicate fish, resembling the English whitebait. About 100 species of insects have been found, of which one half belong to the order *coleoptera*. Mosquitoes and sand flies are plentiful and troublesome in the North island in summer. Spiders are numerous, and two species are said to be poisonous.—The climate of New Zealand is universally described by those familiar with it as one of the finest in the world, and peculiarly adapted to the constitution and habits of the English race. The summer is longer and somewhat warmer than that of England, and the other seasons much

milder, with many more fine days. The worst feature of the climate is the high winds which prevail in some districts, though in many parts the atmosphere is peculiarly serene. The coast climate is the most changeable and the most temperate in the world, the heat varying from 40° to 70°, and occasionally touching both extremes in 24 hours. The mean annual temperature of the North island is 57°, and that of the Middle island 52°. January and February are the warmest months of the year, and June and July the coldest. Snow seldom lies on the ground at the level of the sea, and ice is only occasionally seen in winter. There are neither wet nor dry seasons. A fortnight seldom passes without rain, and rain rarely continues for 3 successive days. The atmosphere is more moist than that of England, and fogs are frequent in the southern part of the group. There is not only sufficient sunshine, however, to ripen every English fruit, but figs, peaches, grapes, nectarines, melons, and maize thrive well in the open air. Spring begins in September, summer in December, autumn in April, and winter in June. The summer mornings are always cool and exhilarating, and the summer nights often singularly beautiful and mild. It is said that the Anglo-Saxon race can work and expose themselves to the climate of New Zealand without injury during more days in the year and for more hours in the day than in any other country. Dr. Thomson says that the remarkable salubrity of the climate "probably arises from the evenness of the temperature at all seasons, the constant agitation the wind produces in the atmosphere, and the circumstance that from whatever quarter the wind blows, it passes over a wide expanse of ocean; in addition to which the country contains few physical sources of disease."—New Zealand is inhabited by British settlers, and by an aboriginal race who call themselves the Maori, and who belong to the Malay division of mankind, and specifically to that portion of it which is found in the Sandwich, Navigators', Marquesas, and Society islands. They are a tall, stout people, the average height of the men being 5 feet 6½ inches, and their average weight 140 lbs. Their shape is peculiar, their bodies and arms being longer and their legs shorter than those of Englishmen of the same stature. The New Zealander's hair is generally coarse and black, though sometimes it is seen of a rusty red tinge. He has good teeth, a short and broad nose, large, dark brown eyes, large mouth, long upper lip, a broad face, a high, narrow, and retreating forehead, and a skin of an olive brown color, which in some is so fair that blushes can be seen, while in a few the skin is dark almost to blackness. The countenances of the New Zealanders are singularly grave and thoughtful, and do not often betray the emotions of the mind. The women are not so handsome as the men, though when young they are graceful and pleasing, with mild eyes, soft, sweet, pathetic

voices, and great ease of manner. In that peculiar disfigurement of the human body known as tattooing the New Zealanders have outstripped all other people. Tattooing on the face they term *moko*, and on the body *whakairo*, the term tattoo, though of Polynesian origin, being unknown in their dialect. The male New Zealanders tattoo their faces, hips, and thighs; and the women tattoo their lips, chins, and eyelids, and occasionally draw a few lines on their bodies. The figures of the tattoo are alike among persons of the same tribe. The pigment used is charcoal made from kauri gum and from other vegetable substances. Under the skin the charcoal looks blue, and grows less dark in the course of years. The origin of tattooing seems to have been a desire to look fierce in battle; but since the introduction of firearms, by which fighting is carried on at a distance, this motive has ceased to operate, and tattooing is going out of fashion, though it is sometimes resorted to as a means of concealing the advance of years, for it makes the old look young. The heads of the New Zealanders are on an average smaller than those of Europeans, and their intellectual faculties inferior in the qualities that derive their cultivation from a knowledge of the past and of the wisdom of others. They are deficient in reason and judgment, have little imagination, and are seldom capable of generalizing. They, however, possess strong memories and quick perceptions, such as are commonly acquired by perpetual activity of the external organs of sense. Their fables, traditions, and songs show a good deal of wit and humor, qualities which are also often displayed in their conversation. They are fond of simple and noisy music, and have an accurate perception of musical time. They comprehend pictures with difficulty, and do not understand the blending of colors; their language has no word for blue. In general it may be said that they have the minds of children and the passions of men. In character they are vain, proud, arrogant, and revengeful, hospitable to strangers, but not generally benevolent, affectionate to their friends and kindred, honest and observant of their promises. They are cheerful in disposition, and consider it disgraceful to give way to anger. In their habits they are dirty and indolent, but are less addicted to intoxication than most savages. When found by the Europeans they were divided into 18 nations, which were again subdivided into a number of tribes. Each tribe acknowledged a chief as its head, who in his turn regarded the chief of the nation as his lord. Each nation was divided into 6 classes: the *ariki*, or principal chief, who was also high priest; the *tana*, or family of the principal chief; the *rangatira*, or inferior chiefs; the *tutua*, or middle classes; the *ware*, or lower classes; and the *taurakareka*, or slaves. The succession of chiefs was hereditary, and they had both civil and ecclesiastical jurisdiction, but could do little without the sanction of the

majority of the people. The peculiar institution of the *tapu* or taboo, with its superstitious observances, by which certain things or persons were made sacred for longer or shorter periods, was of much political value, and was freely used in governing and restraining the common people. The New Zealanders worshipped various gods, apparently personifications of natural objects and powers, to whom they addressed prayers and offered sacrifices. Their gods were spiritual and invisible, and they paid no worship to idols. Many of the gods were deified men, ancestral chiefs of the tribe or nation by whom they were worshipped. They believed in a future state of existence, and that there was an immortal spirit within their bodies. There were two distinct abodes for departed spirits, neither of which was a place of punishment, evil deeds being punished not in the next world but in this, by sickness and other personal misfortunes. They had no idea at all of the resurrection of the body. Their priests were supposed to be in communication with the gods, and to express their wishes and commands. Sorcerers were thought to possess great powers, and were held in peculiar dread. The moral code was adapted to various social conditions and circumstances. Among chiefs courage, liberality, command of temper, endurance of torture without complaint, revenge of injuries, and abstinence from insult to others, were regarded as virtues; obedience to their masters and respect for the taboo were the peculiar virtues of slaves; among married women fidelity to their husbands constituted virtue. A ceremony called *iriiri* or *rohi* was performed by the priests upon infants before they were a month old, and consisted of a species of baptism, sometimes by sprinkling, sometimes by immersion in a stream. When first visited by Europeans, the New Zealanders lived in fortified villages called *pahi*, which were built on peninsulas or on the tops of steep hills. Since the general introduction among them of Christianity, these forts have been abandoned, except a few that are conveniently situated, and the natives live in unguarded villages and farm houses. The different nations were almost constantly at war with each other, and civil wars between the tribes of a nation were not uncommon. These contests were carried on with ferocious barbarity; the defeated tribe was reduced to slavery, or killed and eaten, cannibalism being universal. Quarrels about land and about women were the usual causes of strife, but wars were not entered upon without a good deal of deliberation and attempts at conciliation and mediation. During war sea fights occasionally took place between fleets of canoes, these vessels for military purposes being made 80 feet long, 4 feet wide, and 4 feet deep, and propelled by 50 paddles on each side. The weapons used in war before the introduction of firearms were slings, javelins, long spears made of pine, hardened by fire and sharp at both ends, and clubs and tomahawks

of greenstone or other hard stones. Bows and arrows they were acquainted with, but did not use in war. Of late years these weapons have all been laid aside, and firearms adopted. Wars among the aborigines in fact have nearly ceased, the cessation of slavery and of cannibalism having removed many of the inducements to strife. The last known instance of cannibalism was in 1843, and slavery has quietly died out under the influence of Christianity and the British government. Marriage among the New Zealanders was not connected with any religious ceremonies. Before marriage girls not betrothed in infancy were permitted to indulge in promiscuous intercourse if they pleased, and the more lovers they had the more valuable were they reckoned. Married women, however, were kept under strict restraint, and infidelity was punished severely, often with death. Polygamy was permitted, and men could divorce their wives simply by turning them out of doors. Since the introduction of Christianity a great change has taken place among the aborigines of New Zealand. They are now generally clothed like civilized men, and possess flocks, herds, furniture, houses, and cultivated lands. One half of the adult natives can read and write, and two thirds of them belong to Christian churches. It seems probable, however, that from various causes, especially from the introduction of new diseases, the New Zealanders have been diminishing in numbers for the last 80 years. The aboriginal population, formerly computed at 100,000, was found by an enumeration in 1858 to be little more than half that number.—The language of the New Zealanders is a dialect of the Polynesian tongue generally spoken by the brown races of the Pacific islands, and was derived originally from the Malay. The alphabet, as it has been reduced to writing by the English missionaries, consists of 14 letters: A, E, H, I, K, M, N, O, P, R, T, U, W, Ng. The language is characterized by the simplicity of its grammatical forms, and the absence of distinctions in gender; declension and conjugation are effected as in English by particles, and superlatives are made by reduplication. Among the priests a sacred language was in use, unintelligible to the common people, and containing many Sanscrit words. It is now nearly extinct. A considerable body of literature was preserved by tradition in the shape of fables, stories, proverbs, songs, and laments for the dead. Their poetry is mostly lyrical, and none of it is epic or dramatic. Each sentence is metrically arranged, but rhyme is not used. The prose stories are of great length, some of them requiring successive days for their narration. In style and spirit they resemble children's tales. Several collections of this literature have been made by Englishmen, among them *Ko nga moteatea me nga Hakiara O nga Maori*, "Poems, Traditions, and Chants of the Maories," by Sir George Grey, K.C.B. (Wellington, 1858).—The British colonists have divided New

Zealand into 7 provinces, of which 4 (Auckland, Taranaki, Wellington, and Hawke's Bay) are in the North island, and 3 (Nelson, Canterbury, and Otago) in the Middle island, the South island being also included in the province of Otago. The chief town and capital of Auckland, the most northerly province, is the city of the same name, which occupies a fine commercial position on a narrow isthmus between two deep gulfs, and is well built, with a population of 10,000. It has 2 semi-weekly and 2 weekly newspapers. It is the seat of government not only for its province but for the whole of New Zealand. The Bay of Islands, a small settlement on a fine harbor 50 or 60 m. N. of Auckland, is much resorted to by American whalers, and is the seat of a U. S. consulate. The capital of Taranaki is New Plymouth, on the W. coast near Mt. Egmont, in a region remarkable for salubrity, the beauty of its scenery, and the fertility of the soil. In 1859 the population was about 3,000. The capital of Wellington is a town of the same name on a beautiful bay opening into Cook's strait, and surrounded by scenery which has been compared to that of the bay of Naples; it is subject to frequent earthquakes; pop. in 1859, 8,000. Napier, a small village on the S. E. coast, is the seat of government for the province of Hawke's Bay. Nelson, the capital of the province of the same name, is on Blind bay at the N. end of the Middle island. It enjoys a more equable, serene, and dry climate than any other part of New Zealand, and has a population of 10,000 in its immediate vicinity. The capital of Canterbury is Christchurch, on the small river Avon on the E. side of the island; pop. 8,000. Dunedin on the S. E. coast is the capital of Otago, the most southern province; pop. 2,000. The colonists of New Zealand have been mostly of a class much superior in education, wealth, and social position to those of any other English colony. The imperial parliament in 1852 sanctioned a constitution for New Zealand, of which the main provisions are as follows. The 7 provinces possess distinct governments, consisting of a superintendent and provincial council elected for 4 years by a suffrage nearly universal. The government of the whole colony is vested in a governor appointed by the crown, and in a general assembly consisting of a legislative council and a house of representatives, the latter having 36 members elected for 5 years, and the former 15 members nominated for life by the governor. Both in the general and provincial administrations the principle of responsible government is carried out, and legislative majorities, as in England, create and turn out cabinets. The colonists of New Zealand are mostly employed in agriculture, and their exports consist of potatoes and other provisions and timber to Australia, and of wool, tallow, spars, flax, gums, and copper ore to England. The value of the exports in 1857 was £369,394, and of the imports £992,994. The revenue in 1857 was

£348,357, and the total expenditure of the government £390,957. The British troops in the same year numbered about 1,800 men. The intercourse with the United States is confined to the visits of a few whalers, mostly to the Bay of Islands. Education has been liberally provided for, chiefly by the church organizations of the colony, and there are good schools in all the towns. In 1851 the number of persons belonging to Protestant denominations was 22,673, of whom 14,179 were of the church of England; and there were 3,473 Roman Catholics and 65 Jews. There are church of England bishops at Auckland, Wellington, Nelson, Whaiapu, and Christchurch, and a Roman Catholic bishop at Wellington. In 1858 there were 15 newspapers published in the colony, one of them in the native language, 4 semi-weekly, and the rest weekly.—The Maori, or aborigines of New Zealand, according to their own traditions, came originally from a place called Hawaiki, which the most recent investigators suppose to have been Savaii in the Navigators' islands. Their traditions still speak of Raratonga, Parima, and Manono, well known islands of that region. In consequence of civil war their ancestors to the number of 800 emigrated from Hawaiki in 20 large canoes about A. D. 1400, and after a voyage of 3,000 miles reached New Zealand, which they found uninhabited. The discovery of New Zealand by Europeans is claimed by the French, Spaniards, and Dutch. It is asserted that Binot Paulmier de Gonneville, a French navigator, visited the country in 1504, and that Juan Fernandez reached it from the W. coast of South America in 1576; but these visits are of doubtful occurrence. The Dutch navigator Tasman, with two ships from Batavia, anchored (Sept. 18, 1642) in a bay in the Middle island, next to that in which the town of Nelson now stands. He had an encounter with the natives, in which he lost 4 men, and departed without having landed, calling the place Massacre bay, and naming the country New Zealand. A century later Capt. Cook, during his voyage to the southern hemisphere to observe the transit of Venus, landed at Turanga in the province of Auckland in 1769, and took possession of the country for the crown of England. Three years later a French navigator, Marion du Fresne, arrived with two ships in the Bay of Islands, and after a month's friendly intercourse with the natives offended them by violating the taboo and putting some of their chiefs in irons, and was accordingly attacked and killed with 25 of his men. Capt. Cook subsequently visited New Zealand 4 times, and introduced pigs, potatoes, and other useful animals and vegetables. A few years later English and American whalers began to frequent the coast, and a number of runaway sailors took up their abode among the people and married native women. European visitors were generally treated with kindness, though in 1809, the captain of the English ship Boyd having flogged and otherwise ill-treated a chief

at Wangaroa, his tribe in revenge massacred the crew and passengers of the ship to the number of 70. In 1820 Honga Hika, the most distinguished of New Zealand chiefs, visited England, where he was received with attention by George IV. and loaded with presents, with which he returned to his own country, where he speedily introduced among his people the elements of civilization and Christianity; for though he did not become a Christian himself, he intrusted his children to be educated by the missionaries, who had first visited New Zealand in 1814, under the lead of the Rev. Samuel Marsden, and whom he always protected and encouraged. In 1833 the British government appointed a resident at New Zealand, and in 1838 Capt. Hobson was sent to the islands as lieutenant-governor, the European population at that time exceeding 1,000 persons, and the number of vessels, chiefly whalers, entering the Bay of Islands in that year amounting to 130. The number of converts made by the missionaries was at this time about 4,000. In the following year the New Zealand company was chartered in England with a capital of £500,000, the earl of Durham, Francis Baring, and other eminent statesmen and merchants being at its head; and systematic colonization was commenced by a settlement at Port Nicholson on Cook's strait. In 1844 a serious war broke out with the natives, in which the town of Kororareka, an English settlement, was destroyed, and the English troops repeatedly defeated. Peace was restored in 1848, and shortly afterward a severe earthquake shook a large portion of New Zealand, doing much damage and causing great alarm. In 1850 Canterbury province was settled on church of England and aristocratic principles, a bishop, priests, lords, baronets, and gentlemen of all the professions being among the early settlers. Two years before the province of Otago had been settled exclusively by members of the Free church of Scotland. These colonies are however now composed of persons of every variety of Christian faith. In 1855 a second war with the natives broke out in Taranaki province, about land claims, which ended in 1857. In the present year (1860) a third war originating from the same cause exists in the same province.—See "The Story of New Zealand," by Arthur S. Thomson, M.D. (2 vols., London, 1859).

NEWARK, a city of New Jersey, and the capital of Essex co., situated on the W. bank of Passaic river, about 9 m. W. from New York, and 49 m. N. E. from Trenton, the capital of the state, in lat. 40° 44' N., long. 74° 10' W.; pop. in 1810, 6,000; in 1830, 10,995; in 1840, 17,290; in 1850, 38,894; in 1860, 72,179. The area of the town proper embraces between 4 and 5 sq. m., although the corporate limits comprise much more territory. The main street, called Broad street, is a very spacious and handsome avenue, 132 feet wide and 2½ miles long, shaded with majestic elms, adorned with numerous tasteful edifices, and skirting

in its course three parks. The central park, which the settlers laid out for a "training place," is completely embowered with towering elms, and is surrounded by the mansions of many of the wealthy inhabitants. The other streets of the town are generally wide and airy. The city has largely extended itself in every direction within the last 25 years. That portion through which the New Jersey railroad now passes was a swampy uninhabitable marsh when the road was laid out in 1832; but it is now the seat of numerous manufacturing establishments. Beside the churches, the most noteworthy structures are the custom house and post office, erected by the general government, the mutual benefit life insurance building, the Newark banking company, savings institution, and mechanics' bank, all of freestone of elaborate workmanship. The city is supplied with water collected from a large number of springs on the neighboring high grounds into a reservoir, and thence distributed by pipes. It is also supplied with gas, and has a system of sewerage. There are several cemeteries in the vicinity, the oldest of which is Mount Pleasant cemetery. It occupies 40 acres of land about 2 m. N. of the city, extending from the rolling bank of the Passaic to the Belleville road, and it is elegantly laid out in winding avenues thickly shaded by ornamental trees and flowering shrubbery. The number of churches is 58, of which 5 are Baptist, 6 Episcopal, 12 German of various denominations, 12 Methodist, 14 Presbyterian, 3 Reformed Dutch, 4 Roman Catholic, and 2 Universalist. The oldest edifice is the first Presbyterian church, which was opened in 1791; the 2d church was erected in 1808, the 3d in 1824, and the 4th in 1831. In 1801 the first Baptist society was constituted, in 1806 the first Methodist, in 1834 the first Reformed Dutch, and in 1824 the first Roman Catholic. Newark has since become the see of a Roman Catholic bishop. The public school system has been brought to a high degree of excellence, and affords the means of a liberal education to all the children of the city, free of expense. Evening schools are also provided for adults. The board of education is composed of two commissioners from each ward, chosen by the people, and they appoint a general superintendent of schools. There is a high school, comprising a male and a female department, the pupils of which are admitted on account of superior proficiency in the lower schools, of which there are about 40. The whole number of pupils registered in 1859 was 9,588. The expense of the system was about \$64,000, of which the city raised by tax \$58,000, the remainder being received from the state fund, and the interest on bequests. The cost of tuition averages \$7.22 for each scholar; and the average pay of teachers is \$358.76 per annum.—The municipal government is lodged in the mayor and common council, with independent boards of education, excise, streets, and aqueduct, all elected by the people. The

mayor holds his office for 2 years. The city is divided into 12 wards, each of which is represented in the common council by 2 aldermen, who hold their offices for 2 years. The fire department comprises 618 men, who are paid \$30 a year each; they are under the direct supervision of a chief engineer, with 4 assistants, who are appointed by the common council. There are 2 fire wardens for each ward, who inspect buildings and perform other duties requisite for security. The apparatus consists of 12 hand engines, 2 steam fire engines, 2 hook and ladder trucks, 2 hose carriages, and 13,000 feet of hose. The expenses of the department in 1860 amounted to \$44,988. There are 40 public cisterns and 72 hydrants distributed about the city, to supply water for the extinguishment of fires. The police department, of which the mayor is the head, consists of a chief of police, a captain, 2 lieutenants, and 93 policemen, who are all appointed by the common council; the salary of the chief is \$900, of the captain \$700, of the lieutenants \$600 each, and of the privates \$550 each. The alms department is under the supervision of an overseer of the poor, with a superintendent of the almshouse, an almshouse physician, and other subordinate officers. There are two private orphan asylums, supported by voluntary contribution of the citizens. The sanitary provisions are under the management of a board of health, composed of the mayor, the committee of the council on public health, and the health physician, who is appointed by the common council, and receives no compensation. There is also a health inspector. The city is divided into 6 districts, with a physician in each, for the care of the indigent sick. There is also a city dispensary for the supply of medicines to such persons.—Newark has a considerable commercial business. There are 5 banks with an aggregate capital of \$2,108,650; 2 savings institutions; 8 fire and marine insurance companies; and 1 life insurance company, having an issue of over 7,500 policies, averaging about \$3,500 each, and a fund of nearly \$4,000,000. The real and personal property of the place is estimated at \$31,500,000. Ample means of communication with the surrounding country and with other cities are enjoyed. Thirty-two trains of cars on the New Jersey railroad run to and from New York daily, making Newark almost a suburb of that metropolis; and an independent railroad between the two places is in course of construction. Six trains daily each way connect it with Philadelphia and the South. By the Morris and Essex railroad it is directly connected with the N. W. part of the state, and by the New Jersey central railroad with Somerville and Easton. The Morris canal brings the coal of Lehigh valley through the heart of the town. Various plank roads and turnpikes extend out into the surrounding country; and the Passaic river furnishes an avenue for immense quantities of coarse and

heavy freight.—Almost every branch of mechanical industry is pursued in Newark. The following table of manufactures is from the census of 1860:

Manufactures.	No. of establishments.	Value.
Leather.....	18	\$1,118,000
Patent leather.....	11	2,089,300
Patent or enamelled cloth.....	7	961,650
Saddles and harness.....	17	1,314,150
Saddlery hardware, collars, whips, &c.....	15	301,350
Trunks and carpet bags.....	9	944,000
Trunk rivets, frames, bands, &c.....	5	162,500
Carriages and wagons.....	27	771,450
Spokes, rims, wheels, hubs, axles, &c.....	24	812,214
Plated ware for carriages, harness, and saddles.....	22	588,500
Shoes.....	55	614,075
Skates.....	1	5,000
Straps, bands, and belting.....	8	463,000
Hats.....	21	1,527,878
Straw hats and millinery.....	3	106,500
Hat blocks, tips, blowing fur, &c.....	5	21,000
Clothing.....	41	2,610,023
Shirts, hosiery, cloth, and silk.....	10	847,400
India rubber goods.....	2	406,000
Table covers.....	1	86,000
Jewelry.....	24	1,188,000
Jewellers' tools, britannia and Japan ware.....	7	42,900
Iron, brass, and malleable iron.....	18	895,750
Machinery.....	18	755,750
Tools, pipes, gas fittings, tin ware, shears, cutlery, locks, railings, &c.....	61	1,009,750
Building and builders' materials.....	52	794,940
Furniture, &c.....	9	120,300
Mattresses, hangings, needles, buttons, brushes, type metal, &c., including 9 printing establishments.....	67	777,110
Lime and cement, chemicals, varnish, glue, lampblack, zinc paint, &c.....	16	930,500
Ale and lager beer.....	16	808,595
Bread, &c.....	18	271,717
Miscellaneous.....	44	598,542
Total.....	547	\$28,264,818

—Newark was settled in May, 1666, by about 80 families from Milford and New Haven, Conn., under the lead of Capt. Robert Treat, afterward governor of that colony, to which he returned at a later period. In 1667 they were joined by about an equal number of settlers from Guilford and Branford, Conn., under the lead of the Rev. Abraham Pierson, their minister, who, having in early life preached in Newark, England, gave that name to the new town. Their object seems to have been to establish a Puritan community, to be administered under the laws of God, by members of the church, on strictly democratic principles. They left Connecticut because the colony of New Haven, to which they belonged, had been united to the Connecticut colony of Hartford, a union which interfered with their independence. The proprietors of New Jersey had just issued their liberal proposals to settlers, known as "the grants and concessions;" and Treat and Pierson, with their associates, having obtained from Philip Carteret, the proprietary governor, a license to purchase land, paid to the Indians for the tract which now constitutes Newark, Clinton, Orange, Bloomfield, and Belleville, £130 New England currency, 12 Indian blankets, and 12 Indian guns. The settlers laid out the town plat of Newark, with its spacious

streets and parks as they now exist. A homestead lot of 6 acres was assigned to each settler or head of a family, with out lands and meadow for agricultural purposes, farming having for several generations constituted the main pursuit of the inhabitants. They passed a law that none should become freemen or free burgesses of the town, or vote at its elections, or be chosen to the magistracy, or to any chief military trust or office, but such planters as were members of the Congregational churches; though all others admitted to be planters should have right to their inheritances and all other civil rights and privileges. Their first care was to build a meeting house, and in 1676 a school was established. In 1678 the Rev. Abraham Pierson died, and was succeeded in the pastoral office by his son of the same name, who subsequently removed to Connecticut, and on the establishment of Yale college in 1701 became its first president. In 1736 the Rev. Aaron Burr (whose son, the vice-president of the United States, was subsequently born here) commenced his ministry, and in 1748 became president of the college of New Jersey, which was situated in this town for 8 years; in 1756 it was removed to Princeton. A small commerce was soon created, which constantly increased. Newark cider acquired an early celebrity, which is not yet forgotten. Quarries of brown stone were worked here for market as early as 1721; and the stone was sent before the revolution even as far as the West Indies. Shoes and carriages were manufactured in considerable quantities several years before the commencement of the present century. The population, which in 1683 was 100 families, is said to have amounted to only 1,000 souls in the revolutionary war, doubtless owing in good measure to the troubles of that period. During the revolution, the town was successively occupied by the American and British troops, and was subject to occasional incursions from New York. Upon the establishment of peace, however, it received a new impulse, and soon became very prosperous. The present academy was established in 1792, the brick edifice, which formerly occupied the site of the new post office, having been built in that year. In 1794 the bridges over the Passaic and Hackensack were erected, and communication with New York, which had previously been carried on by means of ferries, was opened over the present causeway or turnpike between Newark and Jersey City. In 1804 the first bank was established, with a capital of \$400,000, and in 1812 a second bank was instituted. The Morris canal, which connects Newark with Easton, Penn., and the Lehigh valley, was completed in 1832; the New Jersey railroad, between Newark and Jersey City, was opened in 1834. In 1834 Newark was made a port of entry, and in 1836 it was incorporated as a city.

NEWARK, the capital of Licking co., Ohio, situated at the confluence of 8 branches of the Licking river, and on the Ohio canal, 88 m. E.

by N. from Columbus, and 24 m. W. by N. from Zanesville; pop. in 1850, 8,654; in 1860, estimated at 6,000. In the vicinity are quarries of sandstone and an extensive coal mine, and a number of coal oil factories. In 1859 the town contained 8 churches (1 Baptist, 1 Episcopal, 1 Lutheran, 2 Methodist, 2 Presbyterian, and 1 Roman Catholic), a bank, a private banking house, 3 newspaper offices, and several factories. It is on the line of the central Ohio railroad, and is the terminus of the Sandusky, Mansfield, and Newark railroad.

NEWAYGO, a W. co. of Mich., intersected by the Maaskego river and drained by Notipeaskago, White, Marquette, and other streams; area, about 800 sq. m.; pop. in 1850, 510. The soil is fertile. The productions in 1850 were 7,200 bushels of Indian corn, 2,230 of potatoes, and 122 tons of hay. Capital, Newaygo.

NEWBERN, a port of entry and capital of Craven co., N. C., on the S. W. bank of the Neuse at its confluence with the Trent, 30 m. from its mouth in Pamlico sound, and 120 m. S. E. from Raleigh; pop. in 1850, 4,800. The Neuse, which is here over a mile wide, is navigable for 8 months in the year. Ocracoke inlet affords communication with the sea. The port has considerable commerce, principally domestic, and exports large quantities of grain, lumber, tar, turpentine, and naval stores. Its foreign exports for the year ending June 30, 1859, amounted to \$11,811, and its imports to \$13,878. This trade is confined to the West Indies. The aggregate tonnage of the district at that date was 3,446. The town contains several flour and saw mills, a theatre, 2 banks, and a number of churches. It was at one time the capital of the province of North Carolina.

NEWBERRY, a central district of S. C., bordered N. E. by Broad and S. by Saluda rivers, and drained by Ennoree and Little rivers; area, about 600 sq. m.; pop. in 1850, 20,143, of whom 12,688 were slaves; white pop. in 1859, 7,021. It has an undulating surface and a fertile soil, especially near the streams. The productions in 1850 were 664,058 bushels of Indian corn, 79,575 of wheat, 99,798 of oats, 79,132 of sweet potatoes, and 19,894 bales of cotton. There were 10 grist mills, 5 saw mills, 4 tanneries, 89 churches, and 1,181 pupils attending public schools. The Greenville and Columbia railroad passes through the capital, Newberry, which is also connected with Laurensville by the Laurens railroad.

NEWBURG, a township and village and semi-capital of Orange co., N. Y., on the W. bank of the Hudson river, 61 m. N. from New York and 84 m. S. from Albany; pop. of the township in 1860, 15,400; of the village, about 11,000. The village is situated on a steep slope rising from the river to a height of 150 feet. It contains a court house, and a number of manufacturing establishments, among which are 5 founderies; a cotton manufactory, employing 825 hands, and turning out goods to the annual amount of \$200,000; an extensive brewery, a

car factory, 2 pianoforte factories, 5 soap factories, boiler works, and 2 other manufactories; and owns shipping to the amount of about 4,000 tons. Its receipts of lumber by railroad in 1858 amounted to 21,000,000 feet, and 20,000 bunches of shingles. There are 23 churches (8 Episcopal, 4 Presbyterian, 2 Reformed Presbyterian, 1 United Presbyterian, 1 Reformed Dutch, 7 Methodist, 3 Baptist, 1 Roman Catholic, and 1 Universalist), 5 banks, and several private schools and academies. Water is supplied to the village from Little pond, 8 m. distant, the works for which cost \$96,000. "Washington's Head-Quarters," an old stone mansion overlooking the Hudson, is owned and kept in order by the state. Beside its association with the revolutionary war and its great chief, the building contains numerous interesting relics of that period. A ferry connects the village with Fishkill Landing, a station on the Hudson river railroad, on the opposite side of the river; and it is connected by the Newburg branch with the New York and Erie railroad.

NEWBURYPORT, a city and port of entry, and one of the shire towns of Essex co., Mass., situated on the right bank of the Merrimack river, 8 m. from its mouth, and 84 m. N. by E. from Boston, in lat. 42° 48' 30" N., long. 70° 52' 8" W.; pop. in 1860, 18,406. The eastern railroad passes through it, and it is also connected with Boston and the interior by the Newburyport railroad. It is situated on a swell of land rising gradually to the height of 100 feet from the river, and commands a fine view of the ocean and the surrounding country. The streets are laid out regularly, and finely shaded with trees; and High street, the principal thoroughfare, extending for 3 m. parallel to the river, and about a quarter of a mile from it, is regarded as one of the most beautiful streets in New England. In the centre of the city is a fine mall, extending around a beautiful pond of 6 acres. Near the city is Oak-Hill cemetery. The principal public buildings are the custom house, city hall, court house, and 16 churches, some of them of admirable architecture. Under the Federal street church are the remains of the Rev. George Whitefield, who died here in 1770. The same church contains a whispering gallery, where a slight whisper can be heard 115 feet. There are 8 banks of discount with an aggregate capital of \$650,000, and 2 savings banks with deposits to the amount of \$1,800,000. The city has 4 manufacturing corporations with an aggregate capital of \$1,080,000, employing 1,400 hands, running 67,000 spindles, and manufacturing 10,000,000 yards of cotton cloth annually. There are also manufactories of machinery, castings, hats, leather, combs, jewelry, shoes, cordage, &c. Ship building forms a prominent business of the place. Vessels were built here as early as 1680, and in 1766 there were 72 vessels on the stocks at one time. In 1854, 20,000 tons of shipping of different kinds were built, the vessels varying from 100 to 1,600

tons, and employing 1,000 men. Since that time the business has been depressed there as elsewhere. The harbor is formed by the position of Plum island along the mouth of the river, and is safe and commodious. The channel, however, is shifting and shallow from the accumulation of sand, which has always proved a serious inconvenience. The commerce of the port for the year ending June 30, 1859, was as follows: vessels entered, 66, tonnage 5,345; vessels cleared, 78, tonnage 8,187; value of imports, \$80,055; of exports, \$98,417. The registered shipping of the port at the above date was 22,913 tons; enrolled and licensed, 6,940; total, 29,853. Two newspapers are published, a daily and a weekly. The former, the "Newburyport Herald," has been established 75 years. Its first proprietor and printer was Edmund Blunt, author of the "Coast Pilot," and the first press used was purchased of Benjamin Franklin for \$40. The public schools of Newburyport have for a long time occupied a high rank. The female high school was the first of the kind established in the country. The Putnam free school, supported by a fund of \$50,000, is a school of the higher grade, open to all without regard to residence. A free library, founded in 1856 by a donation of the Hon. Josiah Little, contains upward of 10,000 volumes, and is constantly increasing. —Newburyport was settled about 1635, but until 1764 formed a part of Newbury. It was distinguished for its patriotic spirit during the revolution. The first tea destroyed was in this town, having been taken from a powder house, where it had been deposited for safe keeping, and burned by the citizens in the public squares. The expedition to Quebec sailed from this port for the Kennebec. The first privateer fitted out in the United States was from this port, and the first volunteer company to join the continental army was here formed in response to an appeal of the clergy. On May 31, 1811, a great fire destroyed a large portion of the town and over \$1,000,000 worth of property. In the war of 1812 Newburyport was particularly distinguished for the bravery and success of its privateers. In 1851 a portion of Newbury was annexed to the town, and on May 24 of the same year a city charter was obtained. The first mayor of the city was the Hon. Caleb Cushing. Newburyport was the residence of Chief Justice Parsons, Jacob Perkins, Judge Jackson, and other eminent persons. Many distinguished families of the United States originated from this town; and among its transient visitors and residents have been many foreigners of distinction, as Talleyrand and others. The home of the eccentric Timothy Dexter still forms one of the curious localities of the place. Prominent among the clergy of Newburyport for the last 50 years, until his death in 1859, was the Rev. Dr. Dana, once president of Dartmouth college.

NEWCASTLE, WILLIAM CAVENDISH, duke of, a royalist general in the civil wars of England, born in 1592, died in 1676. He was the

nephew of William Cavendish, founder of the ducal house of Devonshire, and succeeding in 1617, upon the death of his father, to large estates, devoted himself principally to poetry, music, and other elegant accomplishments. In 1620 he was raised to the peerage as Baron Ogle and Viscount Mansfield, and in 1628 was created earl of Newcastle-upon-Tyne. At the outbreak of the civil wars he sided with the king, to whose treasury he contributed £10,000, and took the field at the head of a body of 200 cavaliers. He was intrusted by the king with the command of the 4 northern counties, and raising in a short time an army of 10,000 men, he succeeded by a series of vigorous movements in prostrating the power of the parliament in that part of England. His most memorable achievement was the total defeat of Sir Thomas Fairfax at Atherton Moor, June 30, 1643. For these services he was in November of the same year created marquis of Newcastle. Subsequently he held the Scots in check at Durham, but was obliged in April, 1644, in consequence of the defeat of Col. Belasis at Selby, to throw himself with all his forces into York, where for the next 8 months he sustained an investment by a greatly superior army under Fairfax. Upon the advance of the royal army under Rupert to his relief, he joined the latter with the greater part of the garrison, and endeavored to persuade him that, having accomplished the raising of the siege, he had better defer a general engagement until the arrival of the expected reinforcements. His advice was disregarded, and the fatal battle of Marston Moor was fought, which ruined the royal cause in the north. The marquis behaved with determined gallantry in this engagement, and his regiment, composed of his old tenants and retainers, distinguished by their white coats, forming a circle, poured repeated volleys into the ranks of the enemy, until, "their ammunition being spent, an opening was made, and the white-coats perished, every man falling on the spot on which he had fought." He forced his way with a few followers to Scarborough, and, weary of a charge which ill suited his elegant and studious habits, set sail for the continent, and established himself in Antwerp. His estates having been sequestered by parliament in 1652, he lived in extreme poverty during the protectorate; but upon the restoration he became the recipient of various substantial honors, and in March, 1664, was created earl of Ogle and duke of Newcastle. Clarendon says he was "a very fine gentleman, active and full of courage," as also "amorous in poetry and music, to which he indulged the greater part of his time." He was the author of "A New Method to Dress Horses" (published in French at Antwerp in 1658, and afterward in English, with alterations, at London in 1667), and of several comedies. His duchess, the eccentric Margaret of Newcastle, to whom he was married in 1645, has sketched his character and career in her

"Life of the thrice Noble, High, and Puissant Prince William Cavendish, Duke, Marquis, and Earl of Newcastle" (fol., London, 1667).—MARGARET CAVENDISH, duchess of, second wife of the preceding, an English authoress, born at St. John's, near Colchester, Essex, about the end of the reign of James I., died in 1678. She was the youngest daughter of Thomas Lucas, who died early, leaving the instruction of the children to their mother; although in Margaret's case not much education would seem to have been necessary, as she herself informs us that "it pleased God to command his servant nature to indue her with a poetical and philosophical genius even from her birth, for she did write some books even in that kind before she was 12 years of age." Joining the court at Oxford in 1643, she was appointed a maid of honor to Queen Henrietta Maria, and accompanied her to Paris, where she met the marquis of Newcastle. After their marriage in 1645 they removed to Rotterdam, and subsequently to Antwerp, where they lived for a time in such extreme destitution that they were once compelled to pawn their clothes. At the restoration they returned to England, and in 1664 the marquis was created a duke. The remainder of their lives they spent in retirement, perpetrating an unlimited amount of bad prose and worse poetry. Both in conversation and in print, each spoke of the other as the greatest genius in the world, the duke, among other things, being likened by his consort to Julius Cæsar. While in Antwerp he had published in 1658 his work on horsemanship, and had composed at the instigation of his wife some comedies, and also wrote, as we are carefully informed, the more licentious passages in hers. She, however, was much the more voluminous author of the two, nothing being too high or too low for her to attempt; and as she never revised her works "lest it should disturb her following thoughts," she was enabled to produce 18 folios, 10 of which are in print. Walpole, in his "Catalogue of Royal and Noble Authors," reports that she kept a servant who slept on a truckle-bed in her room, and when during the night she felt inspiration, she would cry out: "John, I conceive;" whereupon he would arise and commit to paper what she dictated. The best known of her works are her two volumes of plays, in which the absurdity of the matter is only rivalled by the disregard of grammar, for which, indeed, she expresses the most profound contempt in several of her numerous prefaces and "Addresses to the Reader." Yet during her lifetime she was made the subject of the most fulsome panegyric by eminent men and learned societies. She was buried in Westminster abbey. Her works are much sought after on account of their rarity and absurdity.

NEWCASTLE, or NEWCASTLE-UNDER-LYME, THOMAS HOLLES PELHAM, duke of, an English statesman, born July 21, 1694, died in 1768. He was the son and successor of Thomas Pel-

ham, first Baron Pelham, and in 1711 came into possession of the large estates of his maternal uncle, John Holles, duke of Newcastle, whose title expired with him. In 1714 he was created Viscount Haughton and earl of Clare, and in the succeeding year marquis of Clare and duke of Newcastle-upon-Tyne, with remainder, failing his issue male, to his brother. He entered political life as a whig and a supporter of the house of Hanover, in whose interests he raised a troop of horse to put down the Jacobites. Rewarded for his loyalty by admission into Walpole's ministry as secretary of state, he succeeded by industry, influential connections, and lavish expenditure of money, and also by the assistance of his brother Henry Pelham, in making himself feared and respected by those who despised his abilities, which were beneath mediocrity. He remained in office during the administration of Henry Pelham, and in his pride of power so irritated George II. that the latter complained that he could not appoint even a page of the back stairs, while there were so many of the Newcastle footmen about him. In 1746 the Pelham brothers, apprehensive that the king was endeavoring to bring Lord Granville into power, suddenly resigned office with all their colleagues. An abortive attempt was made to form a new ministry, and at the end of 40 hours the old cabinet was recalled, the king complaining bitterly that a man like Newcastle, who was not fit, he said, to be chamberlain to a petty court in Germany, should be forced on him and the nation as a minister. Upon the death of Henry Pelham in 1754, the duke succeeded to the premiership, but resigned in 1756 from inability to reconcile the discordant elements in his cabinet. In 1757 he was reinstated in office, with Pitt and Henry Fox as his chief supporters in the ministry, but was so overshadowed by the greatness of the first of these that he sank into insignificance and retired in disgust in May, 1762. In Nov. 1756, he was created duke of Newcastle-under-Lyme, with special remainder to Henry Fiennes Clinton, 9th earl of Lincoln, who had married his niece, and who inherited the title in 1768. His administrative incompetency, and the long period (amounting to nearly 40 years) that he held office, are among the anomalies of British political history. "No man," says Macaulay, "was ever so unmercifully satirized. But in truth he was himself a satire already made. All that the art of the satirist does for other ridiculous men nature had done for him. Whatever was absurd about him stood out with grotesque prominence from the rest of the character. He was a living, moving, talking caricature. His gait was a shuffling trot; his utterance a rapid stutter; he was always in a hurry; he was never in time; he abounded in fulsome caresses and in hysterical tears. His oratory resembles that of Justice Shallow. It was nonsense effervescent with animal spirits and impertinence."

"He was greedy after power with a greediness all his own. He was jealous of all his colleagues, and even of his own brother. Under the disguise of levity he was false beyond all example of political falsehood. All the able men of his time ridiculed him as a dunce, a driveller, a child who never knew his own mind for an hour together, and he overreached them all round." A similar estimate of his character was entertained by contemporary and subsequent writers. Sir Robert Walpole, against whom he had intrigued, declared that "his name was perfidy;" and Horace Walpole has in his correspondence painted him in the blackest colors.—HENRY PELHAM FIENNES PELHAM CLINTON, duke of, a British statesman, born in London, May 22, 1811. He was educated at Eton, where he was contemporary with Mr. Gladstone and Mr. Charles Kean, and at Christchurch, Oxford. In 1832, as Lord Lincoln, he was returned to the house of commons for the family borough of Newark, and at once attached himself to the conservative party, of which his father was a member, of the most extreme tory school of opinion. Subsequently he was returned for South Notts, in which shire his family have large possessions. On Sir Robert Peel's being called from Italy in 1834 to form an administration, Lord Lincoln was appointed to a lordship of the treasury, and held that office during the few months Sir Robert Peel retained the reins of power. In the interval between this and Peel's return to power in 1841, Lord Lincoln was a prominent and active member of the opposition party, and was rewarded by the appointment, on the construction of Peel's government, of the office of chief commissioner of woods and forests, a position which he filled with considerable credit down to 1846. A large portion of the conservative party having in that year, under the lead of Lord Stanley and Lord George Bentinck, seceded from Peel's standard, in consequence of his change of views on the corn law question, Lord Lincoln adhered to his chief, and, in order to give him the strength which the approving fiat of a large agricultural constituency like South Notts would afford, exchanged his position of commissioner of woods and forests for the somewhat inferior one of chief secretary for Ireland, which involved a new election. He was defeated in South Notts in consequence of his father, who disapproved of the step he had taken, using all his influence against him, and compelled to fall back for a seat on the Falkirk district of burghs, which was in the gift of his father-in-law, the duke of Hamilton. He retired from office with Sir Robert Peel in the autumn of 1846, but retained his seat; and up to the period of his elevation to the house of lords (Jan. 12, 1851), as one of the leaders of the small but brilliant band of Peelites he exercised considerable influence, more by the weight of his character and his untiring industry and conscientious sense of duty, than by any readiness

in debate. At the close of 1852 he became secretary of state for the colonies in the Aberdeen ministry, in which capacity the functions of minister of war devolved upon him. Shortly after the outbreak of the Crimean war the colonial department was separated from that of war; and the duke, choosing the latter, received in 1855 a share of the blame which was thrown upon the administration on account of the misconduct of that war, and resigned his office after defending himself in the house of lords with great spirit. He afterward visited the Crimea, and was there at the capture of Sebastopol. In 1859 he became a member of Lord Palmerston's administration as colonial secretary, and in 1860 was selected by the queen to accompany the prince of Wales on his visit to Canada and the United States.—He is said to have been the model of Disraeli's "Coningsby." He married in 1832 the only daughter of the late duke of Hamilton, a faithless wife, from whom he was divorced in 1850. She bore him many children, the eldest of whom, Henry Pelham Alexander, earl of Lincoln, was born Jan. 25, 1834.

NEWCASTLE-UNDER-LYME, a municipal and parliamentary borough and market town of Staffordshire, England, near the right bank of the Trent, 150 m. N. W. from London; pop. in 1851, 10,569. It is well built, paved, and lighted with gas. The principal public edifices are the churches, town hall, literary and scientific institute, theatre, free grammar school (founded in 1602), and a range of almshouses for 20 poor females. It has manufactories of silks, cotton, earthenware, &c.; coal and iron are mined in the vicinity. The borough returns two members to parliament.

NEWCASTLE-UPON-TYNE (anc. *Pons Ælii*, afterward *Monkchester*), a city and river port of England, capital of Northumberland, and a county in itself, situated on the left bank of the Tyne, 8 m. from its mouth in the German ocean, and 303 m. by railway N. N. W. from London; lat. 54° 58' N., long. 1° 35' W.; pop. in 1851, 87,784. It is built on 3 steep hills, and extends about 2 m. along the river, communicating with Gateshead on the opposite bank by a handsome stone bridge. A few remains of its ancient fortifications are yet standing. The streets, except in the old quarters, are spacious, well paved, and lighted with gas, and many of the houses and public buildings are remarkably elegant. The churches of All Saints, St. John, St. Peter, St. Nicholas, St. Thomas, and St. Andrew, and the magnificent Roman Catholic church of St. Mary, the guildhall, corn exchange, new town hall, merchants' court, gaol, court house, house of correction, barracks, and central railway station are particularly deserving of notice. A large semicircular Ionic building is occupied by the central exchange and news room. A handsome edifice was erected in 1859 for public baths and wash houses. The "high level bridge" across the Tyne, built by Robert Stephenson at a cost

of more than £284,000, is supported by 6 massive piers 124 feet apart, and has a carriage way 90 feet above the river, and over that a railway viaduct at a height of 118 feet from the water. There are many hospitals, asylums for the deaf and dumb, and blind, learned and scientific societies, and schools. The museum of the antiquarian society has the largest collection in England of Roman lapidary inscriptions and sculptures. The old castle, built in 1080 by Robert, eldest son of William the Conqueror, is one of the finest specimens of castellated Norman architecture in the kingdom. A theatre, a music hall, and assembly rooms are the principal places of amusement. The chief manufactures are glass of all kinds, iron ware, locomotives, paper, copperas, coal pitch, spirits of tar, varnish, soda, whiting, glue, vinegar, and soap. The Armstrong gun works, erected in 1859, cover an area of 11 acres, and give employment to from 1,200 to 2,000 men. Connected with them are shot, shell, and fuze factories, and a mechanics' literary institution for the benefit of the workmen. Ship building is prosecuted on a large scale, and the construction of iron steamships has lately become a prominent branch of industry. The harbor has been much improved within the last few years by dredging, and there is a fine quay 1,550 feet long. The traffic is principally in coals (bituminous), for which Newcastle is the greatest mart in the world. During the year 1857 the export amounted to 3,855,864 tons, of which 2,082,001 tons were shipped coastwise and 1,773,863 tons to foreign ports. In addition to this, an immense quantity is sent by railway to different parts of the kingdom. The trade seems to have been an important one from the very earliest period of the town; the burgesses obtained from Henry III. in 1239 a license to dig the coals within the borough, and by the time of Edward I. the business had grown to such consequence that Newcastle was able to pay a revenue of £200. In 1615 the trade employed 400 ships, and extended to France and the Netherlands. The exportations of coke are also important, amounting to more than 100,000 tons annually. Lead is shipped in large quantities; it is brought from Cumberland and the hills of western Northumberland and Durham, and is exported both in pigs and in the manufactured state. This traffic is still more ancient than that in coals. The imports are chiefly agricultural products, wine, spirits, colonial produce, tallow, hides, tar, pitch, limestone, bones, bristles, rags, oil, and timber. The following table shows the movement of shipping in 1856:

Character.	Entered.		Cleared.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Steam.....	628	145,777	902	235,070
Sailing.....	6,058	789,660	16,708	2,538,784
Total.....	6,686	935,437	17,610	2,766,854

Of the aggregate tonnage, 291,606 tons inward

and 1,458,789 tons outward were employed in the coasting, and the remainder in the foreign and colonial trade. The registered shipping of the port was 562 sailing vessels of 127,918 tons, and 104 steam vessels of 8,985 tons.—Newcastle derived its ancient name of Pons Ælii from a bridge over the Tyne attributed to the emperor Hadrian, and its subsequent one of Monkchester from its monastic establishments. The holy well of Jesus Mound (now called Jesmond), about a mile from the town, was a favorite resort for pilgrims. During the reign of Charles I. the city was taken by the Scottish army under Lesley. The borough is governed by a mayor, 14 aldermen, and 42 councillors, and returns two members to parliament.

NEWCOMBE, WILLIAM, an English prelate and biblical critic, born in Berkshire in 1739, died in Dublin, Jan. 11, 1800. He was educated at Oxford, and distinguished himself as a tutor, Charles James Fox being one of his pupils. He became bishop of Dromore in 1766. In 1775 he was translated to Ossory, in 1779 to Waterford, and in 1795 was made archbishop of Armagh. The most important of his works are: "The Harmony of the Gospels" (1778); "Observations on our Lord's Conduct as a Divine Instructor" (1782); "New Critical Version of the Twelve Minor Prophets and Ezekiel" (1785-'8); "An Historical View of the English Biblical Translations" (1792); and "An Attempt toward Revising our English Translation of the Greek Scriptures" (1796).

NEWELL, SAMUEL, an American missionary, born in Durham, Me., July 24, 1784, died in Bombay, March 30, 1821. He was graduated at Harvard college in 1807, and having studied theology at Andover, offered himself as a missionary to the general association of ministers at Bradford, June 27, 1810; was ordained together with Judson, Nott, Rice, and Hall, at Salem, Feb. 5, 1812; and sailed two weeks afterward in company with Judson for Calcutta. On his arrival the Bengal government ordered him to leave the country, whereupon he sailed for the Isle of France, thence to Ceylon, and finally in 1817 joined Mr. Hall at Bombay, where he remained until his death. He was one of the signers of the paper which led to the formation of the American board of commissioners for foreign missions, and was one of the first to engage personally in that work. In conjunction with Mr. Hall he wrote the "Conversion of the World, or the Claims of Six Hundred Millions" (Andover, 1818).—HARRIET, wife of the preceding, one of the first female missionaries from the United States, born in Haverhill, Mass., Oct. 10, 1798, died in the Isle of France, Nov. 30, 1812. Her maiden name was Atwood. At the age of 15 she made a profession of religion, and resolved to devote herself to the work of a missionary. She was married to Mr. Newell in Feb. 1812, and accompanied him to India. On the passage from Calcutta to the Isle of France she gave birth to a daughter, who lived only a few days, and shortly

after their arrival Mrs. Newell died of consumption. Her memoirs, by Dr. Leonard Woods of Andover, have passed through many editions, and have given a powerful impulse to the missionary cause in this country.

NEWFOUNDLAND, an island forming the most eastern part of North America, lying at the mouth of the gulf of St. Lawrence, and belonging to Great Britain. Its northern point is in lat. 51° 37' N., separated from Labrador by the straits of Belle Isle, which are 12 m. wide. Its extreme length N. and S. is about 490 m. The southern coast of the island reaches to lat. 46° 38', and extends E. and W. about 320 m., or from long. 51° 40' to 59° 31' W. Cape Ray, its S. W. point, is about 70 m. distant from Cape North, the nearest point of Cape Breton island. Its area is about 36,000 sq. m.; pop. in 1858, 119,886. The island is triangular in form, and has a coast line of nearly 1,000 m., everywhere indented with deep bays, but especially broken on the S. E. and E. From Cape Bauld at the N. to Cape Freels, about the middle of the E. coast, extends a wide basin of the Atlantic enclosing Hare, Canada, and White bays, the bay of Notre Dame, bay of Exploits, and Sir J. Hamilton's sound. Immediately S. of Cape Freels is Bonavista bay. In the S. E. the large peninsula of Avalon, very narrow at the neck and spreading as it extends seaward into three smaller peninsulas, runs out between Trinity and Placentia bays. Its coasts are broken by Conception and St. Mary's bays. At its S. extremity is Cape Race, off which is stationed the news yacht to intercept steamers from Europe and despatch their news by telegraph to the press of the United States. Between Placentia and Fortune bays, on the S. E. and S. coasts, another long peninsula stretches toward the S. W.; a few miles W. of its point lie the islands of Miquelon, Langley, and St. Pierre. Hermitage bay is the only other large indentation on the S. coast, and St. George's bay and the bay of Islands are the principal ones on the W. The W. coast is much more regular than any of the others. Good harbors abound, particularly in the S. E., where is situated the capital, St. John, with a fine port; but the entrance to many of the harbors is obstructed by rocky ledges. The general aspect of the coasts as seen from the sea is rugged, precipitous, and uninviting, the rocky cliffs rising from the sea to a great height, and being clad with a scanty vegetation.—In the interior there are numerous lakes and ponds which give rise to several rivers, of which the river Exploits, flowing into the bay of the same name, the Humber into the bay of Islands, and the Gander into Sir J. Hamilton's sound, are the most considerable. Few of the streams are navigable, and even the Indian canoe can scarcely overcome the difficulties occasioned by their frequent falls and rapids. The largest lakes are Red Indian, the source of the river Exploits, 80 m. long and from 5 to 6 m. wide,

and Grand pond, 50 or 60 m. long and 5 m. wide. It is estimated that about $\frac{1}{4}$ of the surface of the island is covered with fresh water. There are no mountains, but the interior is diversified by hills, the highest of which are not more than 1,500 feet above the sea. The elevated and exposed tracts, which are called "barrens," are generally destitute of vegetable soil, and covered with a thin and dwarfish growth of shrubs and trees. In the lowlands there are marshes covered with peat moss, and swamps of juniper, cedar, and spruce, which render the country almost impenetrable. As the agricultural resources are inconsiderable, and neither the timber nor minerals very important, the interior has been but little explored. The principal trees are the fir, spruce, birch, larch, willow, and mountain ash, all being of small size, and growing close together in a tangled maze, with the branches interlacing and reaching to the ground. Agriculture employs a large part of the population, but it is only in the S. E. that much effort has been made to form settlements and clear the land. The soil and climate are better suited to pasturage than tillage. Potatoes and grain are the principal crops. The fauna includes the deer, bear, wolf, hare, beaver, marten, dog, and wild cat. The Newfoundland dog, so famous for its size, sagacity, and fidelity, is now rarely found of pure blood, the animals commonly known by its name being crosses of innumerable varieties. The morse or sea horse, which formerly abounded on the coast, has almost or wholly disappeared, but seals are numerous.—The geological structure of Newfoundland is pretty well understood from the fine exposures of its rock formations as they abut in bold cliffs around its coast. Everywhere deep indentations extend up into the island, the general direction of which is toward the N. N. E. or the S. S. W., on the line of the range of hills and of the strata of which these are composed. The S. E. portion of the island is made up of metamorphic rocks, as mica and argillaceous slates, granites, gneiss, sienite, porphyry, &c., and among these occur belts of sandstones and conglomerates. No fossils have been met with in these sedimentary rocks by which their age may be determined, but they may evidently be referred to the older members of the palæozoic series. They are associated with serpentine and penetrated by greenstone and other basaltic rocks; and in several localities they present indications of metallic veins, as at Shoal bay, 12 m. from St. John, where a copper mine was opened in 1775 by some Cornish miners; and also at the S. extremity of the island upon the long point between Placentia bay and Fortune bay, where indications of lead and copper are reported to be found. A vein of argentiferous galena was opened upon lands ceded to the telegraph company, and has been worked to some extent. Its locality is on the S. side of the neck of land which separates the peninsula

of Avalon from the main body of the island. In 1856 two copper mines were opened in Conception bay and a third in Placentia, and rich copper ores of the variegated kind have been shipped from them to Liverpool. All along the S. coast the rocks are of similar character to those of the S. E. portion of the island; and the same ranges of rocks were crossed by Mr. Cormack in 1823 along a line from 20 to 80 m. back from the coast, extending from Trinity bay to the W. side of the island at St. George's bay. At the S. W. extremity of the island, the range of the metamorphic rocks gives place to red sandstones and the shales and conglomerates of the coal measures. These contain beds of gypsum, which crop out upon the coast; and in the interior, at several localities within 8 or 10 m. of the shore of St. George's bay, small beds of bituminous coal have been discovered. The formation ranges with the line of the coast, and appears to be repeated behind a narrow belt of metamorphic rocks, which passes nearly N. and S. at a distance of about 80 m. inland from the general line of the coast. Back of this belt is a comparatively smooth and fertile region, stretching toward the N., it is supposed, to the extremity of the island at the straits of Belle Isle. It is reached by a few streams, as the Humber river, Coal river, Great Codroy river, &c. At the head of Grand pond a bed of cannel coal has been found 8 feet thick. The distance to St. George's harbor is about 50 m. down the lake to the foot, and thence overland about 15 m. No attention is given either to the mineral or agricultural resources. Little is known as to the probable importance of the coal beds; the beds of gypsum, which are abundant and very accessible, are wholly neglected; and though limestone abounds, and cliffs of marble (which is reported to be of excellent quality) are found extending for miles along the Humber river, no attempt has yet been made to ascertain their real value. A geological reconnaissance of the coast was made in 1839 and 1840 by Mr. J. B. Jukes, who published a report to the government, and also 2 vols. in 1842 entitled "Excursions in and about Newfoundland." The country is also described in a work by Sir Richard H. Bonnycastle, "Newfoundland in 1842" (London, 1842), which is accompanied by a complete map of the island.—Though from the high latitude of Newfoundland the winters are long and the summers short, the severity of the former is greatly mitigated by the proximity of the Gulf stream. To the same cause are to be attributed the dense fogs which prevail throughout this region; for as the warm and moist airs over the gulf waters meet the cold atmospheric currents from the north, the vapors by their condensation become apparent in the form of heavy fogs. The winter temperature of St. John is so mild that the harbor is rarely frozen over; and the inclemencies of the climate are felt rather in severe storms, which are very prevalent along the coasts, than

in the intense cold of winter. The fogs and violent gales render the coast a dangerous one to navigators, and frequent wrecks occur along the S. side of the island, especially about Cape Race.—The settlements are chiefly on the peninsula of Avalon and at the heads of the bays in this part of the island. The most important, after St. John, are the Bay of Bulls, Brigus, Ferryland, Fermoore, and Renowes. On the western side, which in soil, climate, and mineral wealth possesses great advantages over the eastern, there are but few scattered settlers. Indians of two very distinct tribes, the aborigines or Red Indians, and the Micmacs from New Brunswick, were many years ago numerous upon the island. The former have been entirely exterminated by the whites and the Micmacs. Some of the latter still remain, subsisting chiefly by hunting, and maintaining amicable relations with the colonists. The great business of the people is fishing, in which about $\frac{1}{5}$ of the inhabitants are in some way or another engaged. About 850 vessels are employed in catching seals, 80 in the coast and bank fisheries, and more than 10,000 in taking cod. So predominant is the importance of this last branch, that in Newfoundland the term "fish" is generally understood to mean only cod. The value of boats, nets, and other apparatus used in the business is estimated at \$2,500,000, and the average annual product at \$6,000,000. The yield may be set down in round numbers as 1,000,000 quintals of cod, 5,000 tierces of salmon, 20,000 barrels of herrings, 500,000 seal skins, 6,000 tons of seal oil, 4,000 tons of cod oil, &c. In consequence of the reciprocity treaty, the exports of codfish from the port of St. John to the United States almost tripled within two years, rising from 21,386 quintals in 1853 to 60,257 in 1855. In 1855 the exports of Newfoundland amounted to £1,142,212, of which £594,969 went to British possessions and £79,984 to the United States; the principal articles were: cod, £680,288; salmon, £18,758; herrings, £19,794; cod oil, £146,645; seal oil, £154,624; blubber and dregs, £2,408; seal skins, £46,886; total export of products of fisheries, £1,088,258. The imports during the same year amounted to £1,152,804, of which £555,591 came from British possessions and £354,489 from the United States. The principal articles imported were: flour, £268,067; bread, £144,737; woollens, £88,184; pork, £70,212; butter, £51,888; cotton goods, £49,912; leather and leather manufactures, £49,204; molasses, £39,808; and sugar, £32,870. The commerce for the years 1853, '4, and '5 is shown in the following table:

Years.	Vessels entered.		Vessels cleared.		Value of imports.	Value of exports.
	No.	Tonnage.	No.	Tonnage.		
1853.....	1,221	184,423	1,050	194,448	£912,095	£1,170,503
1854.....	1,043	129,229	987	117,198	964,527	1,018,572
1855.....	1,077	140,461	968	181,868	1,152,904	1,142,212

—The present form of government of the island was established in 1855, in accordance with

which the governor (in 1860, Sir Alexander Bannerman) is to act with the assistance and advice of an executive council. The legislature is composed of the governor, the legislative council, the members of which are appointed by the crown, and the general assembly, the members of which are elected by the people. The revenue in 1855 was £126,449, and the expenditures £120,926. The public debt of the colony is upward of £150,000. The contribution of the home government to the colony in 1857 was £20,114. In 1855 there were 218 schools, attended by 13,602 scholars, and the amount paid from the colonial revenue for public education was nearly £9,000. About £18,000 were expended for the relief of the poor. The Episcopal church numbered 42,000 members, the Roman Catholic 56,000, and the Wesleyan Methodist 18,000. No denomination is especially supported by the government, except that the Episcopal bishop receives £800 a year from the British treasury.—Newfoundland was discovered June 24, 1497, by John Cabot, who with his son Sebastian was engaged upon a voyage of exploration under the commission of Henry VII. He made the land at a place on the E. coast which he called Bonavista, a name it still retains. Cabot called the peninsula at the S. E. extremity of the island St. John, because it was discovered on St. John's day. In 1500 the island was visited by the Portuguese navigator Gaspar de Cortereal, who discovered and named Conception bay. The Portuguese in 1501 and 1502 established regular fisheries on the shores, and the Biscayans and French soon engaged in the same enterprise. (See FISHERIES.) Several expeditions were fitted out by the English and French with the intention of colonizing the island, but none of them were successful up to 1578, when there were 50 ships belonging to England engaged in the fishery, as many to Portugal, and 150 to France and Spain. On Aug. 5, 1583, Sir Humphrey Gilbert, in command of 4 armed vessels, entered the harbor of St. John and took formal possession of the island in the name of Queen Elizabeth. He established laws regulating the fisheries, and levied contributions on the ships of all nations found within 200 leagues of St. John. The expedition soon came to a disastrous termination by the wreck of the vessels and the loss of their commander while recrossing the ocean. Other attempts to colonize the island were afterward made, the least disastrous of which was that of Mr. Guy, a Bristol merchant, in 1610, who founded a colony at Mosquito cove in Conception bay, which lasted two years. In 1615 Capt. Richard Whitbourne, of Exmouth in Devon, was sent by the admiralty to Newfoundland to establish order among the fishermen and correct the great abuses that prevailed. He made an attempt to impanel juries in the most frequented harbors, and was the first to introduce the forms of law in British America. In 1618 he again visited the island and with aid to the colony of Dr. Vaughan in

the southern part, at the place now known as Little Britain. The settlement of Sir George Calvert, afterward Lord Baltimore, was made in 1621, and included the S. E. peninsula, to which he gave the name of Avalon. He built a large house at Ferryland and a strong fort at Isle aux Bois. But not long afterward he abandoned Newfoundland for Maryland, where he obtained another large grant. In 1626 the cod fishery of Newfoundland was of such importance that 150 vessels were sent out from Devonshire alone. The trade was grievously harassed by pirates and by the rivalry and opposition of the French. Charles I. in 1633 established a code of regulations; and in 1635 permission was granted to the French to cure and dry fish in Newfoundland, they paying 5 per cent. of the produce for the privilege. In 1660 they founded a colony in Plaisance or Placentia bay, which the English destroyed in 1692. Until the peace of Utrecht in 1718 the ports were frequently the scenes of warfare between the English and French, one and the other power alternately gaining possession of them. The English government was also opposed to the settlement of their own people, and broke up their establishments on the ground of their being likely to monopolize the fishery, and prevent it from becoming a nursery for British seamen. The treaty of Utrecht gave Great Britain the sole sovereignty of the island, but permitted the French to catch and dry fish on the N. and parts of the E. and W. shores. In 1763 the French again obtained possession of St. John, but were soon driven out by the English under Lord Colville. The next year the treaty of Paris was ratified, by which the French yielded their claims to the colonies of British America, retaining the right to fish in the gulf of St. Lawrence 3 leagues from its shores, and 15 from those of Cape Breton, and possession of the rocky islets of St. Pierre and Miquelon on condition of not using them for military purposes. From 1759 to 1767 Capt. Cook, the famous navigator, was employed as a naval officer in the English service on this station, and became eminent for his industry and skill as a marine surveyor. The only surveys of the coast upon which the present maps are based were made by him, and his marks are still to be seen at the S. W. part of the island. By his observation of an eclipse of the sun, Aug. 5, 1766, compared with observations made at Oxford, the longitude of Cape Ray was first determined. In the progress of the troubles between Great Britain and the colonies, which led to the revolutionary war, Newfoundland suffered extremely from the non-intercourse act passed by the first congress and carried out in 1775. Dependent upon New England for supplies to the annual value of nearly £350,000, when these were suddenly cut off and the coast and harbors were ravaged by American privateers, the inhabitants were reduced to the greatest distress before they could be relieved by the protective measures of the

mother country. On the restoration of peace in 1788 the citizens of the United States retained the right to fish as previously, but could cure and dry their fish only in the unsettled bays, harbors, and creeks of Nova Scotia, the Magdalen islands, and Labrador. The population in 1785 was 10,244, and 8,084 acres of land were under cultivation. From this time the prosperity of the island has been but little interrupted. In 1807 the first newspaper, "The Royal Gazette and Newfoundland Advertiser," was published. In 1809 Labrador and the island of Anticosti were annexed to the government of Newfoundland. The colonial government granted in 1854 a charter to the "New York, Newfoundland, and London Telegraph Company," for the purpose of establishing telegraphic communications between Europe and America. Subsequently the land wires were completed between St. John and the cable terminus at Cape Ray, and the "Atlantic Telegraph Company" was established in 1856 to extend the existing line to Ireland.

NEWFOUNDLAND DOG. See Dog.

NEWMAN, JOHN HENRY, D.D., an English clergyman, and superior of the English congregation of the Oratory, born in London, Feb. 21, 1801. He was graduated at Trinity college, Oxford, and was elected fellow of Oriel college. In 1824 he was ordained, but his life at Oxford was essentially academic, occupied with the duties of his fellowship, and with those that devolved upon him afterward as vice-principal of St. Alban's hall in 1825 and 1826, tutor of Oriel in 1826, and public examiner of the university in 1827 and 1828. In 1828 he succeeded Dr. Hawkins as vicar of the church of St. Mary the Virgin; his sermons in that church gained for him the reputation of a remarkable preacher. In 1838 he published "The Church of the Fathers," which is noteworthy as showing the course his mind was taking toward the Roman Catholic church. About this time appeared also his treatise on the Arians of the 4th century. During the years that the "Tracts for the Times" were in course of publication, he was a large contributor to them. He also wrote and published a treatise on "Justification," contributed articles to the "British Critic," published a work on the four "Prophetical Offices of the Church," and took part in preparing the "Library of the Fathers." The views of the theological school of which he was really the head, though it took its name from another of its members, Dr. Pusey, excited general attention, especially among the members of the Anglican and Protestant Episcopal churches. The excitement was brought to its height by the publication of tract No. XC., the author of which was Dr. Newman, in which he tried to show that the 89 articles of the church of England might be subscribed consistently with a belief in the decrees of the council of Trent. This excited a violent opposition. Shortly afterward he retracted certain bitter expres-

sions he had used in writing of the church of Rome; he resigned the vicarage of St. Mary, and retired to Littlemore, near Oxford, where he remained a long time in strict seclusion. Finally, on Oct. 9, 1845, he was received into the Roman Catholic church by the provincial of the Passionist Fathers in England. From Littlemore he went to St. Mary's college at Oscott, and thence to Rome, accompanied by some and followed by others of his old disciples. He received the priesthood in Rome, and embraced the institute of the Oratory, founded by St. Philip Neri. On his return to England in 1848 he established the congregation of the Oratory, and shortly after opened the first house in Edgebaston, Birmingham. Some statements, made in one of a series of lectures delivered and afterward published by him on the "Present Position of Catholics in England," with regard to the ex-Dominican monk Dr. Achilli, involved him in a suit for libel. The suit was decided against him, not without a protest against the verdict as unfair from the "Times" newspaper and other sources. The costs of the suit, about \$46,000, were paid by a subscription from all parts of the world amounting to \$64,000. The surplus was divided by him between a religious community and the Catholic university of Ireland, the latter receiving \$16,000 and the former \$2,000. Upon the foundation of the Catholic university of Ireland (1852) Dr. Newman was made its first rector, but has since resigned that position, and returned to the Oratory at Birmingham, where he is at present engaged in an English translation of the Holy Scriptures, confided to him by Cardinal Wiseman and the other Roman Catholic bishops of England, with the approbation of the pope. Beside the works already mentioned, he wrote, before he became a Roman Catholic, "Parochial Sermons" (6 vols.), "Essay on Ecclesiastical Miracles," "Sermons preached before the University of Oxford," and an "Essay on the Development of Christian Doctrine;" and since his conversion he has published "Sermons to Mixed Congregations," "Occasional Sermons," "Lectures on Anglican Difficulties," "Discourses on University Education," "Office and Work of Universities," "Lectures on the Turks," "Loss and Gain," and "Callista," the last two being works of fiction.—FRANCIS WILLIAM, an English author, brother of the preceding, born in London in 1805. He was graduated at Worcester college, Oxford, in 1826, with first class honors in both classics and mathematics. In Nov. 1826, he became a fellow of Balliol college, which position he resigned in 1830, being unable conscientiously to sign the 39 articles previous to taking the degree of M.A. The 3 following years he spent in various parts of the East, in Aleppo, Bagdad, Teheran, Tabriz, and Constantinople; and on his return to England in 1834 he became classical tutor in Bristol college. This situation he occupied until 1840, when he was chosen classical professor

at Manchester New college, and in 1846 was appointed professor of the Latin language and literature in University college, London, which position he still holds. He has written many works on historical, political, and especially theological subjects, in which he has taken an exactly contrary course to that of his brother. He has also written much for reviews and for the newspaper press. Among his theological works may be mentioned "Catholic Union: Essays toward a Church of the Future and the Organization of Philanthropy" (8vo., 1844); a tract entitled "A State Church not Defensible" (1846); "A History of the Hebrew Monarchy, from the Administration of Samuel to the Babylonish Captivity" (1847); "The Soul, its Sorrows and Aspirations" (1849); "Phases of Faith, or Passages from the History of my Creed" (1850); and "Theism, Doctrinal and Practical" (1858). Among his political and historical works are: "Four Lectures on the Contrasts of Ancient and Modern History" (1847); "An Appeal to the Middle Classes on the urgent Necessity of numerous Radical Reforms, Financial and Organic" (1848); "On the Constitutional and Moral Right or Wrong of our National Debt" (1849); a tract on "The Crimes of the House of Hapsburg against its own Liege Subjects" (1851); "Lectures on Political Economy" (1851); and "Regal Rome, an Introduction to Roman History" (1852). He has also published "A Collection of Poetry for the Practice of Elocution" (1850); "Odes of Horace translated into unrhymed Metres" (1853); "The Iliad of Homer translated into unrhymed Metres" (1856). He assisted in editing a translation of Huber's work on "The English Universities" (1848), and in 1853 brought out an edition of the "Select Speeches of Kossuth." He is likewise author of "Lectures on Logic," of a "Grammar of the Berber Language," and of a work on the "Difficulties of Elementary Geometry."

NEWMARKET, a market town of England, consisting mainly of one long street, wide and well lighted, the N. side of which is in Suffolk, and the S. side in Cambridgeshire, 13 m. E. by N. from Cambridge, and 65 m. N. E. from London, with which it is connected by the eastern counties railway; pop. in 1851, 3,356. It contains a corn market, assembly rooms, a handsome church, and a jockey club. It derives its chief importance from the races, 7 of which are held annually, viz.: the Craven, on Easter Monday; the first spring, on the second Monday following; the second spring, a fortnight after that; the July; the first October, held on the first Monday in that month; the second October, on the second Monday following; and the third October, or Houghton, a fortnight afterward. The race course, considered the best in Great Britain, is about 3 m. from the town, and between 4 and 5 m. in circuit. There is also a training ground about 1½ m. long.

NEWPORT, a S. E. co. of R. I., consisting of a portion of the mainland and a number of

small islands in Narraganset bay, including Rhode, Canonicut, Prudence, and Block islands; area, 136 sq. m.; pop. in 1850, 20,007. It has an undulating surface and a generally fertile soil, and contains large quantities of coal. In 1850 the productions were 156,698 bushels of Indian corn, 134,988 of oats, 78,688 of potatoes, 13,776 tons of hay, 48,565 lbs. of wool, and 222,916 of butter. There were 9 cotton and 5 woollen factories, 8 flour mills, several manufactories, 36 churches, and 2,951 pupils attending public schools.

NEWPORT, a post town, port of entry, and the capital of Newport co., R. I., and semi-capital of the state, situated on the W. shore of Rhode island on Narraganset bay, 5 m. from the ocean, in lat. $41^{\circ} 29' N.$, long. $71^{\circ} 19' 12'' W.$; pop. in 1850, 9,663; in 1860, about 10,500. It has a fine harbor, which may be entered at all times without a pilot, and is safe, commodious, and deep enough for the largest ships. It is defended by Fort Adams on Benton's point and Fort Wolcott on Goat island. The town is built on a declivity facing the harbor, and contains a state house, custom house, market house, the Redwood library with 4,000 volumes, the masonic hall, armory hall, and numerous elegant private residences. Its salubrious climate, refreshing ocean breezes, facilities for sea bathing, and charming natural scenery have combined to render it one of the most popular summer resorts in the United States, and the visitors during the fashionable season are numbered by thousands. The whole S. portion of the island is now dotted over with villas, and there are several large hotels, among which may be mentioned the Ocean house at the S. end of Bellevue street, the Atlantic house at the head of Pelham street, the Bellevue house in Catharine street, the Fillmore, and the Aquidneck. The pleasantest part of the town is that which has been built within the last 20 years for the convenience of summer visitors, and which is constantly being added to and improved. The old town is interesting for its quaint and picturesque appearance. The "old stone mill," whose origin and purpose were once a theme of much learned discussion; Fort Brown and its surrounding rocks, called "the dumplings;" Fort Adams, one of the most costly and extensive fortifications in the Union; the "purgatory rocks" and "hanging rocks" at the second beach; the great "spouting cave," and "the glen" are the principal objects of interest. The beaches, called first, second, and third, are not only excellent spots for bathing, but also favorite promenades at low tide. The commerce of Newport is now very limited, and its manufactures are almost confined to a few cotton mills, a shot tower, and lead works. The tonnage of the district on June 30, 1859, was 8,210, of which 8,575 was registered, and 4,635 enrolled and licensed. The exports during the previous year were \$56,026, and the imports \$79,497. Number of vessels clear-

ed, 28, tonnage 5,721; vessels entered, 81, tonnage 7,322.—Newport was settled in 1638 by 17 colonists from Roger Williams's party, headed by William Coddington. The settlers were early distinguished for their enterprise as merchants and navigators, and for their activity in the whaling business. As early as 1764 their trade with the West Indies employed 150 vessels, and 14,000 hhds. of molasses were annually imported, to be converted into rum for the African market. Newport was one of the first places which manifested a spirit of resistance to the arbitrary acts of the mother country, and some years before the Boston tea party the British armed sloop Liberty, stationed here to exact an odious tax, was burned in the harbor. During the revolution 8,000 British and Hessian troops were quartered on the town, and its commercial interests never recovered from the injury which they inflicted. They destroyed 480 houses, robbed the library, then the finest except one in America, burned the shipping, cut down all the groves and orchards for fuel, and carried off the town records. Before this period Newport had been a favorite resort of men of science and letters, and was noted for the opulence and refinement of its inhabitants. Bishop (then Dean) Berkeley resided here 2½ years, and built a house which is still standing. It was here that he composed his celebrated work, the "Minute Philosopher." Commodore O. H. Perry was born near Newport, and is buried there, with a monument to his memory.

NEWPORT, a city of Campbell co., Ky., on the Ohio river, just above the mouth of the Licking, and opposite Cincinnati, 70 m. N. N. E. from Frankfort; pop. in 1860, 10,047. It is built on an elevated plain commanding a fine view of Cincinnati, with which it communicates by a steam ferry; and a splendid suspension bridge over the Licking river connects it with Covington. The villages of Jamestown and Brooklyn are in the immediate vicinity, and contain many elegant residences of the wealthy citizens. There are several rolling mills, iron foundries, an academy, a U. S. arsenal, a bank, and various manufactories.

NEWPORT. I. A municipal and parliamentary borough and market town of Monmouthshire, England, situated on the right bank of the river Usk, about 5 m. from its mouth, and 20 m. S. W. from Monmouth; pop. in 1851, 19,842. It is largely engaged in ship building, and has several iron foundries, nail works, and manufactories of anchors, chain cables, &c. There is a dock capable of admitting vessels of large size. The number of vessels belonging to the port in 1856 was 92, tonnage 16,280. In the same year there cleared from the port 7,826 sailing vessels, tonnage 686,461, and 274 steamers, tonnage 20,087. The town is connected with Gloucester, Cardiff, and Pontypool by railway, and with the last of these places by the Monmouthshire canal. Of the castle of Newport, which is

supposed to have been built by the earl of Gloucester, a son of Henry I., only a square tower and a part of the great hall now remain, and are at present occupied as a brewery. The borough unites with Monmouth and Usk in sending one member to parliament. In 1839 it was the scene of the chartist insurrection for which John Frost and others were found guilty of high treason, and transported for life. II. A municipal and parliamentary borough of Hampshire, England, in the isle of Wight, on the left bank of the river Medina, which is navigable for small vessels, 18 m. S. S. E. from Southampton; pop. in 1851, 8,047. Lace and agricultural implements are manufactured. The borough returns two members to parliament.

NEWPORT, CHRISTOPHER, one of the founders of the colony at Jamestown, Va. He commanded the 8 vessels which carried out in 1606 the first settlers of that colony, and was one of the council for governing the province appointed by the king. After visiting with Capt. John Smith and others the "emperor of the country," Powhatan, he returned to England in June, 1607. He came back the next year with supplies and 120 emigrants, chiefly goldsmiths and gentlemen, "packed hither," says Smith, "by their friends to escape ill destinies." As their object was gold, "there was no talk, no hope, no work, but dig gold, wash gold, refine gold, load gold;" and some yellow mica having been discovered near the present site of Richmond, Newport filled his vessels with it under the impression that it was gold, and carried it to England. He subsequently came back to Virginia in the fleet conveying Lord Delaware and the new charter to the colony, but was wrecked in the Bermudas, where they built a vessel with which they reached their destination. Newport's reputation as a sailor had been acquired in expeditions against the Spaniards. By Smith he is described as "empty, idle, timid, and ostentatious."

NEWPORT, GEORGE, an English naturalist and physiologist, born in Canterbury, July 6, 1803, died in London, April 7, 1854. He acquired by his own unaided efforts a knowledge of natural history, and was appointed curator of the museum of natural history at Canterbury. He subsequently embraced the medical profession, but does not appear to have practised it. He wrote valuable essays on physiology, entomology, and botany, which were chiefly published in the "Transactions" of the royal, the entomological, and the Linnæan societies. During his latter years he enjoyed a pension of £100 from government.

NEWRY, a parliamentary borough and river port of Ireland, on the borders of the counties of Down and Armagh, on the Newry water and canal and the Dublin and Belfast junction railway, 82 m. S. S. W. from Belfast, and 63 m. N. from Dublin; pop. in 1851, 18,191. There are 2 churches of the established religion, 2 places of worship for Methodists, 8 for Presbyterians, and 2 for Roman Catholics. The chief

manufactures are linen, cotton, iron, beer, and cordage; and there are numerous mills, distilleries, and potteries. The town exports large quantities of provisions. Its principal trade is with Liverpool and Glasgow, but it has also some foreign commerce. The river, which is here crossed by 6 bridges, admits vessels of 600 tons to the town and of 1,000 tons 6 m. below. In 1856 the number of vessels registered at the port was 114, tonnage 6,648. The entrances for that year (mostly coastwise) were 824 sailing vessels, tonnage 57,386, and 254 steamers, tonnage 42,115; the clearances were 287 sailing vessels, tonnage 19,474, and 250 steamers, tonnage 42,945.

NEWSPAPERS, printed sheets published at stated intervals, chiefly for the purpose of conveying intelligence on current events. Newspapers were preceded in antiquity by the *Acta Diurna* of the Romans, which were daily, official, written reports of public occurrences; and in modern Europe by periodical publications in manuscript, for which the stirring events in the 15th and 16th centuries created a demand in Germany, Italy, and other countries. Of the origin of newspapers in England, Alexander Andrews says, in his "History of British Journalism" (London, 1859): "First we have the written news letter furnished to the wealthy aristocracy; then, as the craving for information spread, the ballad of news sung or recited; then the news pamphlet, more prosaically arranged; then the periodical sheet of news; and lastly the newspaper." The first regular series of weekly newspapers hitherto discovered was entitled the "Weekly Newes from Italy, Germania, &c." (1622), the "English Mercurie of 1588," long regarded as the first printed English newspaper, having been exposed as a forgery in 1839 and again in 1850 by Mr. Thomas Watts, one of the librarians of the British museum. Prominently connected with most of the early weekly sheets, which appeared under the name of "Weekly Newes," "Times Newes," "Newes," &c., was Nathaniel Butter, who is regarded as the father of the regular newspaper press. The first attempt at parliamentary reporting was made in 1641; the first advertisement was inserted as early as 1648, and the first paper exclusively devoted to advertisements and shipping intelligence appeared in 1657. The news given in the papers treated chiefly of foreign affairs. Home politics were scarcely discussed till after the abolition of the star chamber in 1641. Various partisan sheets were published during the civil war, chiefly under the name of "Mercuries," and counting among their most eminent editors Nedham, Birkenhead, Digby, and Heylin, the last regarded as the ablest of them all. Many of the papers were notorious for their eccentricity and coarseness, and still more for their bitterness. After the restoration the censorship of the newspapers became more stringent. A semi-official organ, edited by Sir Roger L'Estrange, who was the licenser of the press,

and held for some time a kind of monopoly of journalism, was supplanted in 1665 by the "Oxford Gazette," published during the temporary removal of the court to that city on the outbreak of the plague. On the return of the royal family to the metropolis (1666) it appeared as the "London Gazette," and, as the official organ of the government, was placed under the control of the under secretary of state. The press was for a long time subjected to many persecutions, and the licensing act was not abolished until after the accession of William and Mary. In the mean time the first commercial newspaper, the "City Mercury," was published in 1675; the first literary paper, the "Mercurius Librarius," in 1680; the first sporting paper, the "Jockey's Intelligencer," in 1688; and the first medical paper in 1686. From that year to 1692, 26 new journals sprang into existence, including the first bearing the title of a reform paper, the "Mercurius Reformatus;" the first publication in the style of "Notes and Queries," the "Athenian Mercury;" the first ladies' paper, the "Ladies' Mercury;" the first agricultural and an increasing number of literary journals. Daily newspapers did not make their appearance until the 18th century. The first daily morning newspaper was the "Daily Courant" (1702), consisting of but one page of two columns, and containing 5 paragraphs translated from foreign journals. The leading London weekly journals at that time were mostly sold for a penny; supplements with the latest news commanded an extra price. Home affairs were then little discussed; foreign news supplied the staple of newspaper information, and correspondents were employed in the principal cities of Europe. In 1726 appeared the first number of the "Craftsman," which obtained for a time a circulation of nearly 12,000 copies. In 1780 no fewer than 200 half-sheets per month were issued in London alone, beside a number of daily and weekly journals. The aggregate number of copies of newspapers sold in England in 1757 was about 7,000,000; in 1760, 9,000,000; and in 1767 upward of 10,000,000. The "North Briton," edited by Wilkes, who played a part so conspicuous in consolidating the liberty of the press, first appeared in 1762. The "Englishman," established in the same year, attracted attention in 1766 on account of several of Burke's contributions. The letters of Junius began to appear in 1767 in the "Public Advertiser," and contributed powerfully to raise the political importance of the daily press. The leading daily journals of London in the latter part of the 18th century were the "Morning Chronicle" (founded in 1769), the "Morning Post" (1772), the "Morning Herald" (1781), the "Times" (1785), and the "Morning Advertiser" (1794). The "Times," destined subsequently to eclipse all the other English journals, originally appeared under the name of the "Daily Universal Register." It was printed and published by John Walter of Printing House

square, who, in the impression of Jan. 1, 1788, added to the original name of his journal that of the "Times." Its circulation at the beginning of this century was only 1,000 copies a day, while that of several others was in the neighborhood of 4,000. The "Morning Chronicle" and "Morning Post" enjoyed during that period great literary and political importance. Coleridge, Southey, Lamb, Wordsworth, and Mackintosh (the brother-in-law of the editor, Mr. Stuart, afterward editor of the "Courier"), particularly contributed to raise the "Morning Post" to eminence; but the weight of talent still rested in 1812 with the "Morning Chronicle," whose editor, Mr. J. Perry, counted Fox and Sheridan among his active personal friends, and many youthful aspirants to literary fame among his contributors. In 1813 there were 56 journals circulating in London, of which 8 were published every morning, 7 every evening (the first evening paper having been established as early as 1778), 7 every other evening, 16 every Sunday (the first Sunday paper had appeared in 1788), and 18 weekly on other days. The "Courier" was then considered the best informed daily journal, and the newsmen went through the streets blowing their horns and announcing the "great news," "glorious news," "got a shilling for the 2d edition of the Courier." The "Times" was in the mean time fighting its way into the front rank of journalism. Its remarkable success was ascribed to a firm attitude toward the government and a freedom from party ties; to an efficient system in securing the earliest transmission of news; to a constant care in improving the mechanical resources of the paper, and in securing the best available talent; and above all to the application of steam power to its printing press in 1814. On the morning of Nov. 29, 1814, the readers of the "Times" were informed that "the journal of this day presents to the public the practical result of the greatest improvement connected with printing since the discovery of the art itself." The restoration of peace did not diminish the number of newspapers in the United Kingdom, which in 1815 amounted to 254, viz.: 55 in London (15 daily), 122 in other parts of England and Wales, 26 in Scotland, and 49 in Ireland; and Cobbett's weekly "Political Register," established at the beginning of the century, was sold in 1817 to the extent of 50,000 copies per week. The cessation of the war, however, favored a revival of the representation of literature and art in the press. The "Examiner" paid even more attention than ever to literature, and a series of essays, written by Hazlitt in conjunction with Leigh Hunt for that journal, were published in 1817 under the title of the "Round Table." Mr. Barnes, whose talent was, next to the enterprise of Mr. Walter (the son of the original founder), one of the chief instruments in building up the fortune of the "Times," was called to the editorial chair of that journal at about the same time. In 1822

Thomas Moore was invited by Barnes to write leading articles, but declined the proposal; and Southey is also said to have declined the editorship of the "Times," with a salary of £2,000. The growth of English journalism, although most perceptible in the "Times," soon pervaded all classes of newspapers. On Jan. 29, 1829, the "Times" came out on a double sheet, composed of 8 pages of 48 columns. The reform excitement greatly increased the sale of the "Times" and of other journals, and nearly 13,000,000 copies of newspapers passed through the post office in 1830. In 1832 there was one newspaper to every 55,000 of the population, against one to 90,000 in 1821, and one to 110,000 in 1782. The editors of various unstamped newspapers were prosecuted during the discussion on the reform bill. The most violent of them was the editor of the "Poor Man's Guardian," who called William IV. and his ministers "William Guelph and his minions." The "True Sun," edited by the Rev. Mr. Fox, subsequently M. P. for Oldham, now counted Laman Blanchard and Leigh Hunt among its writers, and Charles Dickens among its parliamentary reporters. Douglas Jerrold's and Thackeray's newspaper connections also date from this period. In 1833 the number of journals published in the United Kingdom was about 400, and of copies passing through the post offices of Great Britain and Ireland nearly 42,000,000.—A new stimulus was given to newspaper enterprise in 1836 by the reduction of the stamp duty from 4 pence to a penny, causing in the first year of the full operation of the new act an increase of 8,000,000 in the stamps issued, and of 61 in the number of newspapers, which a year before the reduction was 397, and a year afterward 458. Fourteen of the new journals were established in London alone, including an ultra-liberal morning newspaper called "The Constitutional" (in place of the old "Public Ledger"), of which Laman Blanchard was the editor, Mr. Thornton Hunt the sub-editor, Douglas Jerrold the dramatic critic, and Thackeray the Paris correspondent. But it was soon discontinued, together with many of the others, while the "Public Ledger" was revived as a price-current. A socialist organ was published by Robert Owen, the "New Moral World," and a Chartist organ by Feargus O'Connor, the "Northern Star." The "Economist," celebrated for its collections of financial and commercial statistics and disquisitions, was established in 1837 by Mr. John Wilson (died in 1860), whose ability, first manifested in the conduct of this journal, raised him to the secretaryship of the treasury. The "Illustrated London News" was founded in 1842 by Mr. Herbert Ingram, who remained its principal proprietor until his death. He perished in a steamboat accident on Lake Michigan in 1860. The stamps on newspapers in the United Kingdom increased from 65,000,000 in 1843 to 71,000,000 in 1844. The railway mania produced in London many newspapers devoted to railway matters, their number amounting to

about 80 in 1845, but only 8 of them (the "Railway Times," "Railway Journal," and "Railway Record") survived the crisis of 1846. The "Daily News" was established in 1846, under the editorship of Charles Dickens, who published in it his "Sketches from Italy," but soon yielded his place to Mr. Charles Wentworth Dilke, who established in connection with it the "Express" evening journal. The "Daily News" soon attained a circulation second only to that of the "Times," but has since declined. The ordinary daily circulation of the "Times" rose from 23,000 in 1846 to 29,000 in 1848, and to 36,000 in 1852; and the number is largely increased, and sometimes nearly doubled, on the occurrence of any event of great public interest. In 1854, during the Crimean war, the average daily circulation of the "Times" was 51,648, about double the aggregate of all the other daily morning journals, which was only 26,268. The number of newspaper stamps issued in 1854 in the United Kingdom was about 120,000,000. A powerful impulse was given to the press in 1855 by the total abolition of the stamp duty as a tax, making it optional with the publishers to use the stamp as a means of paying postage on such copies of their impressions as were to be sent through the mails. The following were the most widely circulated newspapers in the United Kingdom at that period:

London daily papers.—Times, 16,000,000; Morning Advertiser, 2,400,000; Daily News, 1,500,000; Morning Herald, 1,160,000.

London weekly papers.—News of the World, 5,570,000; Illustrated London News, 5,630,000; Lloyd's Weekly Newspaper, 5,570,000; Weekly Times, 3,900,000; Reynolds's Weekly Newspaper, 2,500,000; Weekly Despatch, 2,000,000; Bell's Life in London, 1,160,000.

English country papers.—Liverpool Mercury, 912,000; Leeds Mercury, 785,000; Stamford Mercury, 689,000; Birmingham Journal, 650,000; Manchester Examiner, 636,000; Staffordshire Advertiser, 425,000; Leeds Times, 421,000. *Welsh papers.*—Yr Amseran, 237,700; Monmouthshire Merlin, 110,000.

Scottish papers.—Edinburgh: North British Advertiser, 808,000; Scotsman, 858,000. Glasgow: Saturday Post, 727,000; North British Mail, 565,000; Herald, 541,000. Aberdeen: Journal, 200,000.

Irish papers.—Dublin: Telegraph, 959,000; Daily Express, 748,600; Saunders's News Letter, 756,000; Freeman's Journal, 490,000. Belfast: Northern Whig, 262,000; Daily Mercury, 210,000. Cork: Constitution, 205,000.

After the abolition of the stamp duty, the 5-penny papers, including recently the "Times," reduced their price to 4d., the 6-penny weekly papers to 5d., and the 3-penny papers (which were established on the abolition of the 4-penny tax in 1836) to 2d.; while a great number of penny weekly and daily papers have sprung up in the United Kingdom, particularly in London. The principal daily penny papers in London, consisting each of 8 pages, are the "Standard," the "Daily Telegraph," and the "Morning Star," the two last issuing evening penny papers or 2d editions under the name of "Evening Telegraph" and "Evening Star." Some of these penny papers have an immense circulation, and the "Standard" has asserted that on one occasion it printed 100,000 copies. The sale of the two editions of the "Star" for some time ranged between 12,000 and 13,000, and is now (1861)

about \$0,000. There are 10 or 12 local papers in various parts of London which enjoy a considerable circulation, as the "City Press," the "Clerkenwell News," the "Holborn Times," &c. Beside the "Times," the leading full-priced daily journals are the "Morning Advertiser," "Morning Chronicle," "Morning Herald," "Morning Post," and "Public Ledger," each consisting of 8 pages (price 4d.), and the "Daily News" (price 3d.). Mr. Thornton Hunt, who was for some time managing editor of the "Daily News," states that its staff consists of a chief editor, at 18 guineas a week; sub-editor, 12 guineas; second sub-editor, 10 guineas; foreign sub-editor, 8 guineas; writers, about 4 guineas a day, £25; 16 parliamentary reporters, one at 7 guineas, and the others at 5 guineas per week, £87 7s. This estimate is somewhat above the real mark, as are the salaries said to be paid to foreign correspondents. Each paper of any standing must have an establishment at Paris. The head of this, who bears the title of correspondent, is paid 10 guineas a week; a reporter, 8 guineas; office expenses and cost of Paris papers, 5 guineas a week. The agent at Boulogne, who transmits the despatches, has 1 guinea; and the expense of postage is also considerable. A Madrid correspondent is also required at 4 guineas; one at Rome, 4 guineas; Naples or Turin, 8 guineas; Lisbon, 8 guineas; Berlin, 5 guineas; beside correspondents at many other places, who are paid according to the importance of their posts. Then there must be a correspondent at every important seaport in the kingdom, whose duty is to forward any news arriving there, with all possible promptness. A large part of the papers is occupied by reports of the proceedings in the courts, and the corps of reporters for this purpose is large and costly. Public meetings also have to be reported, either by members of the parliamentary corps, or by reporters specially engaged. A scientific man is employed to correct the reports of medical evidence and judicial investigations, where chemistry, botany, or physiology is involved. The city editor has 7 guineas a week for his daily money article; 2 market reporters have each 1 guinea, and 7 other markets are reported at a less rate. The salaries paid for theatrical, musical, and other articles on art, are comparatively small, and vary considerably. There must also be subscriptions to a variety of special publications, and a great number of foreign, colonial, and provincial papers must be had, either by exchange or subscription, amounting say to 150 a day, which are read and their news made up by the sub-editors. The paper must also have friends who will bring intelligence from the various government offices. The news at the clubs, especially the Reform and the Carlton, must be had, and paid for. The expense of sending reporters and correspondents to distant meetings and inquests, and of getting their despatches, is also heavy; sometimes a special railway engine being employed, at a cost of £25

or £30. Railway parcels of news cost from £5 to £7 a week. The overland mail costs about £4,000 a year; but by sharing among 4 papers it is reduced to £20 a week each. The electric telegraph is expensive; but though the charges are high, it is not so costly to the papers as in America, for the reason that it is less used. The expenses of the printing and publication offices also make a serious item. The aggregate weekly expenses Mr. Hunt sets down at £520. The full-priced evening papers are the "Globe," the "Evening Herald," and the "Sun" (4d.). The "Express" and "Evening Journal," branches of the "Daily News" and "Morning Herald," sell for 2d.; and next come the penny evening papers. The "London Gazette" appears twice, and the "St. James Chronicle," "Record," and "Evening Mail" thrice a week. Of weekly papers there are in London upward of 140; but although not all political, they are all more or less newspapers. They include "Punch" and the most celebrated weekly literary organs, as the "Athenæum," "Saturday Review," "Spectator," "Press," &c.; and many papers devoted to special branches of science and art and of occupations and classes of society, as the "Builder," "Bell's Life in London" (sporting), the "Lancet," and many religious papers. Among the weekly papers which reach the highest circulation are the "Illustrated London News," "News of the World," and "Illustrated Times." The "Weekly Despatch" contains an immense quantity of reading matter, and each single number of it weighs 8½ oz. It has suffered from the competition of low-priced papers, but is still in a prosperous condition, owing to its abundance of advertisements, for which it charges higher prices than any other weekly paper excepting the "Illustrated London News." Most of the cheap weeklies are ultra liberal in politics. Their joint circulation is between 400,000 and 500,000 weekly. The total number of newspapers, daily and weekly, in the United Kingdom, was in 1860 upward of 800 (in round numbers, 600 in England, 100 in Scotland, and 100 in Ireland), and about 70,000,000 copies pass through the post office annually, irrespective of a great number sent in parcels by railway and circulated privately. "The Times" continues, in the midst of so many political and social changes, at the head of this vast organization of English journalism. Beside being the leading organ of public opinion in England, it is the chief medium of advertisements. The daily issue of the "Times" is estimated in 1861 at between 50,000 and 60,000. —FRENCH NEWSPAPERS date their origin from the publication of the *Mercurius François* (1605–1645), a kind of historical compilation. Their more immediate prototype, however, was the *Gazette* issued by Théophraste Renaudot in 1631, and continued under the name of *Gazette des recueils* and *Gazette de France* till about 1789, appearing generally once, and for some time twice a week; and in the latter part of its existence, when beside political news it con-

tained advertisements and financial accounts, it appeared daily. A poetical newspaper, which chiefly treated of local gossip and scandal, was published by Loret for about 15 years during the second half of the 17th century, having been first called into life by the desire of Mlle. de Longueville, afterward duchess of Nemours, to know what was going on in Paris. The *Mercur galant* (1672), a species of literary journal, was succeeded by the *Nouveau Mercure* and *Mercur de France*, which last prolonged its existence until 1815. In 1758 Mme. de Pompadour induced Marmontel, after the death of the previous editor, his friend Boissy, to conduct the *Mercur*, and D'Alembert and other eminent men are believed to have written for it. The *Journal étranger*, edited by the abbé Arnaud and Fréroid, and having among its contributors Rousseau, Grimm, and Prévost, existed till 1763, when Arnaud became one of the editors of the *Gazette de France* at a salary of 5,000 francs a year, his coadjutor Suard receiving the same amount. The *Moniteur*, the official organ of the government, was founded in 1760, and treated of moral and political subjects; while some of its contemporaries, especially the notorious *Nouvelles à la main*, contained, beside political news, a budget of scandalous intelligence. From the latter end of the 17th century to the middle of the 18th, many weekly and monthly journals were published in Paris, chiefly of a literary and scientific character, with which the most eminent men of France were connected. The first daily political newspaper was the *Journal de Paris, ou Poste du soir* ("Evening Post"), published in 1777, which maintained itself till 1825. The first political editor who attracted general attention was Linguet, who was connected from 1774 till 1788 with the *Journal de politique et de littérature*, better known under the title of *Journal de Bruxelles*, although it was issued in Paris. Another famous French newspaper of that period was the *Courrier de l'Europe*, published in London (1776-'89) twice a week for 6d. a number, and on the staff of which were Morande, Brissot de Warville, and the count de Montlosier. The revolution gave a powerful impulse to French journalism, and Mirabeau's *Courrier de Provence* (1789) became the precursor of thousands of different newspapers. "In the space of a few months," says Louis Blanc, "France was inundated with printed sheets of every tone and description—weekly, monthly, quarterly; royalist, radical, moderate, and frantic; distilling poison and emitting abuse, disseminating error, encouraging calumny, proclaiming facts, echoing every expression of passionate anger, irradiating every awakening idea." This saturnalia of revolutionary journalism found its climax in Marat's *Ami du peuple*, and ended with the 18th Brumaire, after which all journals excepting 18 were suppressed by the first consul, and under the empire only 5 were permitted to appear, viz.: the *Moni-*

teur, *Gazette de France*, *Journal de Paris*, *Journal des débats* (under the temporary name of *Journal de l'empire*), and *Petites affiches*. The condition of the press did not much improve after the restoration. The censorship was replaced in 1825 by securities to be furnished by each proprietor of a Parisian journal to the extent of 200,000 francs, and somewhat less in the provinces. The increase of the stamp duty from 5 to 10 centimes caused the price of the leading journals to be raised from 72 to 80 francs a year. The *Journal des débats* was originally founded in 1789 by Barrère and Louvet, passed in 1800 into the hands of Louis François Bertin the elder, and has since remained the property of the Bertin family. It was from the beginning conspicuous for the support of law and order and of existing authorities. After the restoration, however, it advocated a moderate liberalism in politics. Geoffroy became early attached to its literary department, and the *feuilletons* (a department of journalism peculiar to the continent of Europe) of the *Débats* have maintained to this day their celebrity. The scientific and learned department of the *Débats* has also enjoyed since 1818 a high reputation. One of its early contributors was Royer-Colard. In literature the *Débats* was the first to hail the advent of the romantic school. Among the other prominent journals during the latter part of the restoration was the *Globe*, which counted among its contributors Guizot, Cousin, Jouffroy, and the duke de Broglie, and afterward Rémusat, St. Marc Girardin, Carnot, and other scholars and writers of a younger generation. Many of its writers were brought into political prominence by the revolution of 1830, after which the *Globe* continued to appear for a few years as an organ of St. Simonism. The *Constitutionnel*, established in the early period of the restoration, was constant in its opposition to the elder Bourbons, and reflected in a great measure the views of aspiring and influential politicians of the higher middle class and of the military and civil aristocracy created by Napoleon. Thiers and Mignet wrote largely for this journal until toward the end of the restoration, when they found a more energetic outlet for their liberal opinions in the *National*; and shortly after the July revolution the *Constitutionnel* lost its political influence. The *National* gained importance about 1828 through the influence of Louis Philippe, Talleyrand, Lafitte, and other opponents of the elder branch of the Bourbons; and its first editorial staff comprised Thiers, Mignet, and Carrel. It contributed powerfully to the overthrow of the government of Charles X., soon after which it became, under the sole editorship of Carrel, equally opposed to that of his successor. Carrel was succeeded in the editorial chair by Bastide, and the latter by Armand Marrast; and the *National* took as prominent a part in the overthrow of Louis Philippe as it had in that of Charles X. The foundation in 1835 of the *Presse*, by Émile de Girardin, at 40 francs a year, half the price

of the leading journals, called the cheap press into existence. A powerful means of the success of the *Presse* and of the *Siècle*, which also reduced its price to 40 francs, was the publication of novels in their *feuilletons*, for which the services of Eugène Sue, Alexandre Dumas, and other celebrated writers were enlisted at extravagant prices. The fortunes of the *Constitutionnel* were also revived under the editorship of Dr. Véron, by the reduction of its price, and by the publication in its *feuilletons* of *Le Juif errant*, for which he paid Eugène Sue 100,000 francs. M. de Ste. Beuve was for a long time its literary critic. Under the direction of Véron, the *Constitutionnel* increased its circulation to upward of 20,000; and the general influence of the cheap press, and its handmaid the *feuilleton*, increased the aggregate of subscribers from 70,000 in 1835, when the number of the principal daily journals in Paris was 20, to 180,000 in 1845, when there were 26. The *Siècle* became the favorite paper of the lower middle classes, and reached in 1846 a circulation of upward of 40,000. Within 8 months after the revolution of 1848, about 400 new journals sprang into existence, many of which were of an ultra socialistic or democratic character. The principal organ of the moderate republicans was still the *National*, and of the more radical party the *Réforme*, founded by Cavaignac and edited by Flocon. After the bloody days of June, 1848, the newspapers were again placed under the necessity of depositing security and paying stamp duty, and many journals of considerable circulation were thereby obliged to stop. The estimated daily circulation of newspapers in Paris in 1850 was, of republican organs, 129,000; Orleanist and legitimist, 83,000; Napoleonist, 65,000; total, 277,000. The *coup d'état* of Dec. 2, 1851, terminated the existence of the celebrated *National*, as well as of many other liberal organs. Among the principal journals which have since been published in Paris, the following 10 commanded in 1855 an aggregate circulation of 161,000: the *Presse*, 41,000; *Siècle*, 36,000; *Constitutionnel*, 26,000; *Pays*, 16,000; *Patrie*, 15,000; *Journal des débats*, 9,000; *Univers*, 6,000; *Assemblée nationale*, 5,000; *Union*, 4,000; and *Gazette de France*, 3,000. The *Constitutionnel*, which was believed to have favored the *coup d'état* under the inspiration of Achille Fould, has passed as well as the *Pays* into the hands of the bankers Mirès since 1852. The *Presse*, with which since 1857 M. de Girardin has had no connection, still shares with the *Siècle* the leading position among the Parisian journals as far as the number of subscribers is concerned. The *Journal des débats* still continues to be the most intellectual and dignified exponent of French journalism. Nearly one half of the total number of periodical publications in France are issued in the metropolis. The number of Parisian journals which treat of politics and public economy, and are consequently under bonds to the government

and liable to a stamp duty of 6 centimes, is estimated in 1861 at about 40, and the non-political publications at nearly 600. The following are the principal political daily journals of Paris, arranged in alphabetical order: *Charivari* (humorous), *Constitutionnel*, *Débat*, *Gazette de France*, *Messager*, *Monde* (ultramontane, successor of the *Univers*, suppressed in 1860), *Moniteur universel* (official government organ), *Patrie*, *Pays*, *Presse*, *Siècle*, *Opinion nationale*, and *Union* (uniting the former journals, *France quotidienne*, and *Écho Français*). "Galvani's Messenger," published daily in English, and giving copious extracts from the journals of London as well as of Paris, was established in 1815. The journals devoted to dress and fashion number about 50, those to medical science and treatment nearly 80, and those to industry upward of 100. Almost all branches of industry and trade have their special organs, as *La lumière*, devoted to photography; *L'innovateur*, relating to shoe and boot making; *Le moniteur de l'épicerie*, groceries; *Le garde-meuble*, furniture; while a large number of journals are exclusively devoted to advertisements. *Figaro* is a satirical semi-weekly paper. The principal illustrated newspapers are the *Illustration*, *Le monde illustré*, *L'univers illustré*, and *Le journal pour tous*, the aggregate circulation of which is about 150,000. The total number of daily and periodical journals published in France in 1861 is about 1,400, nearly 1,100 being devoted to art, science, literature, industry, commerce, and agriculture, and the remainder to political subjects and public economy; the former are exempt from giving bonds and from the stamp duties, while the latter must furnish securities to the government to the extent of 50,000 francs for all journals which appear oftener than twice a week, and of 80,000 francs for all periodical publications issued twice a week or at longer intervals. This is the general regulation in the departments of the Seine, Seine-et-Oise, Seine-et-Marne, and Rhone, so as to include the press of Paris and Lyons. The stamp duty is 6 centimes for each paper in the departments of Seine and Seine-et-Oise (Paris and Versailles), and 8 centimes in the other departments. Foreign newspapers are subjected to the same regulations. The journals published in the seaports of France are better known abroad than the other provincial papers, and contain much shipping and commercial information. This is particularly the case with the *Sémaphore de Marseille*, which circulates extensively in the Mediterranean and Levantine ports, and the *Journal du Havre*, which is well known in adjoining countries. The journals published at Lyons possess more political importance than any of the other provincial French journals, during periods when the press is free, and when political excitement runs high; this is owing to the prominent part which Lyons has always taken in revolutionary eras, and to its importance as the principal man-

ufacturing city of France. There are however well conducted journals in Bordeaux, Toulouse, Grenoble, Avignon, Montpellier, Nantes, Orleans, Rouen, Lille, Metz, Strasbourg, and in all the principal cities and towns of France.—Italian newspapers are traced to the early *gazzettes* of Venice of the 16th century, many volumes of which in manuscript are preserved in the Magliabecchian library, while one printed copy dated 1570 is in the British museum. In modern times the principal newspapers consisted at first only of those serving as official organs of the respective authorities, as the *Diario di Roma* and *Gazzetta di Napoli*. The *Voco della verità*, published in Modena (1831), was conspicuous for its advocacy of ultra conservative principles; and the *Antologia*, published about the same period in Florence, was equally conspicuous for its support of ultra liberal tendencies, and counted among its contributors Mazzini and other young patriots. The total number of Italian newspapers in 1836 amounted to 171, and in 1845 to 205. After the accession of Pope Pius IX. in 1847, Italy produced an enormous crop of new journals, chiefly of a revolutionary character, which were discontinued after the reaction in 1849; and with the exception of Sardinia, the Italian press was again put under restraint until 1859-'60, when a new career opened for Italian journalism. Sardinian newspapers have been free since 1848. Among the principal daily journals of Turin are the *Gazzetta Piemontese*, the official organ of the government; the *Opinione*, which supports the administration; the *Diritto*, the exponent of the most advanced and liberal party of Sardinia, edited by Valerio; the *Unione*, independent of party, but national in sentiment; and the *Gazzetta del popolo* (with 7,000 subscribers), the smallest and cheapest of all the newspapers, and the most influential with the people. Among other daily journals are the *Indipendente*, *Espero*, *Staffetta*, and the *Fischietto*, which last is a kind of "Punch." The principal journals of Genoa are the *Gazzetta di Genova*, the official organ; the *Corriere mercantile*, the representative of the government party; and the *Italia del popolo*, the organ of the republican party. There are also newspapers in most of the other Sardinian cities and small towns.—Spanish newspapers were preceded by periodical publications of extraordinary news, which were often printed or recited in verse, and offered for sale chiefly by blind persons; hence they were called *romances de ciegos*. The first regular newspaper was the court journal, *Diario de Madrid*, established about the middle of the 18th century. The press soon rose to a certain degree of importance, and exercised considerable influence during the war of independence, and especially after the establishment of the liberty of the press in 1834, when nearly 20 political journals sprang into existence in Madrid alone, more than 40 being published there in 1844, the *Heraldo* (moderado organ) commanding the largest

circulation (7,000 daily). Satirical and humorous papers have played an important part in the history of Spanish journalism, and many of the ablest writers are engaged in the conduct of literary, scientific, artistic, and religious journals, the subscription list of one of the latter (*El Catolico*) having comprised at times about 14,000. The number of daily journals published at the beginning of 1861 in Madrid was about 80, the most important of which are the *Clamor publico* and *Espana*.—Portuguese newspapers are confined to the organ of government, the *Diario do governo*, and some half dozen other journals published in Lisbon, and to a corresponding number in Oporto and other cities.—German newspapers were preceded by periodical publications of news, a specimen of the oldest of which, dated in 1495, is preserved in the university library of Leipsic. The first regular series of weekly journals appeared at Frankfort-on-the-Main, the *Frankfurter Oberpostamt-Zeitung*, which is still in existence as a daily newspaper, having been established there in 1616 under the auspices of the postmaster, after the model of a journal which had been founded in 1615 by the bookseller Emmel. This was followed by newspapers in all the principal cities of Germany. Among the most widely circulated journals of the 18th century was *Der Hamburgische Correspondent*, founded in 1714; and at the close of the century appeared the Augsburg *Allgemeine Zeitung*, which has since become the leading journal of Germany. Among the eminent men connected with the editing of newspapers at the beginning of the 19th century were Kotzebue (*Russisch-Deutsches Volksblatt*), Niebuhr (*Der Preussische Correspondent*), and Görres (*Der Rheinische Merkur*). The French revolution of 1830 called into existence several radical journals, as Siebenpfeiffer's *Westbote*, Wirth's *Deutsche Tribune*, and *Der Freisinnige* by Rotteck and Welcker; but most of them were suppressed in 1833. Among the ablest journals published between that period and the revolution of 1848 was the *Rheinische Zeitung*, established at Cologne in 1841, where it continued until 1850. The number of newspapers published in Germany at the time of the revolution (1848-'9) has not since materially diminished, and is estimated at the beginning of 1861 at about 1,400. The following are the principal newspapers of the chief cities of Germany: in Augsburg, the above mentioned *Allgemeine Zeitung*; in Berlin, the *Vossische Zeitung* (circulation about 15,000), the favorite paper of the middle classes; the *Spenerische Zeitung* (about 6,000), established originally by order of Frederick II., generally conservative and semi-reactionary; the *Neue Preussische Zeitung* (about 7,000), the organ of the high tory or feudal party; the *Volkzeitung* (24,000), a small daily democratic sheet of great influence as an organ of the working classes; the *Nationalzeitung* (about 7,500), democratic, one of the best German papers, and having next to the Augsburg *Allgemeine Zeitung* the best for-

sign correspondence; in Cologne, the *Kölnische Zeitung* (22,000), moderately liberal, edited with great ability, and strongly anti-Austrian; in Bremen, the *Weser-Zeitung*, democratic, and conducted with much spirit and ability; in Leipzig, the *Deutsche allgemeine Zeitung*, published by Brockhaus, edited with great talent, and possessing excellent foreign correspondence; in Hamburg, the *Börsenhalle*, *Hamburger Nachrichten*, and *Correspondent*, all very old and solid papers, chiefly commercial, and in the main liberal, although not accustomed to express decided opinions; in Frankfort-on-the-Main, the *Frankfurter Journal* and the *Ober-Postamt-Zeitung*, journals of little ability, but often containing semi-official information of importance; in Vienna, the *Wiener Zeitung*, the official organ of the government; the *Oesterreichische Zeitung*, *Donau-Zeitung*, *Wanderer*, *Ost-deutsche Post*, and *Presse*, generally containing excellent intelligence from the East, but in other respects of little importance; in Stettin, the *Ostsee-Zeitung*, an organ of free trade; and in Hanover, the *Zeitung für Norddeutschland*.—Russian newspapers are indebted for their origin to Peter the Great, who took a personal part in the establishment of the first Russian journal, published at Moscow in 1708. Journals appearing once or twice a week, and devoted to general and special news, are published in almost every chief city of the different Russian provinces; but the two principal seats of Russian journalism are St. Petersburg and Moscow. The daily journals of St. Petersburg may be divided into two classes, those which express on many occasions the opinions of the government, and those which are independent. There is no journal in Russia, however, which corresponds exactly to the French *Moniteur*. The "Gazette of the Senate" is official in regard to the publication of laws, ukases, and other regulations of a strictly administrative character. The *Journal de St. Pétersbourg*, published in French, was under former reigns, and is still generally considered, an organ of the department of foreign affairs. Another daily journal of the same name is now published in Russian, and a third in German. During the reign of Nicholas the "Northern Bee" had a considerable influence as the organ of the then all-powerful secret police, by which it was subsidized; but since the accession of the present emperor, it has been on the wane. The *Invalide Russe*, connected to some extent with the establishment for invalid soldiers, has a semi-official character, particularly in military information and statistics. The "Police Gazette" of St. Petersburg relates chiefly to police regulations. Among the other daily journals are the "Son of the Fatherland," the "St. Petersburg News," and the "St. Petersburg Commercial News," which last is published both in Russian and German. The prominent daily journals of Moscow are: the "Russian Messenger," the "Moscow News," the "Moscow Gazette," and the "Police Ga-

zette." In the Baltic provinces, the cities in which are peopled chiefly by persons of German descent, there are a few daily journals published in German, particularly in Riga. The journals of Finland are published in Swedish, and those of Poland and Lithuania in Polish. The principal of the latter are the "Warsaw Courier," "Daily Gazette," and "Morning Gazette," all published in Warsaw. In Kasan a journal is published in Tartar, and in Astrakhan one in Kalmuck. Odessa, on account of the cosmopolitan character of the population and of her commercial relations, has daily journals in French and Italian, and the "Odessa Messenger" enjoys some reputation. Since the adoption of a more liberal policy by Alexander II. new daily journals have sprung into existence in St. Petersburg and Moscow and other parts of the empire. Of Polish journals published in non-Russian provinces, the Cracow "Time" (*Czas*) is the most important; other principal places of publication are Posen and Lemberg. A Hebrew newspaper appears at Lyck in East Prussia, chiefly for the benefit of the Jewish population of the neighboring Polish and Lithuanian provinces, under the title of *Hammagid* ("The Reporter").—The first regular series of Hungarian newspapers was published in Latin in 1721, and the first in the vernacular tongue appeared in 1781 in Presburg. The principal Hungarian journals shortly before the revolution of 1848-'9 were the *Jelenkor* ("Present Age"), *Világ* ("Light"), *Budapesti híradó* ("Buda-Pesth Intelligencer," edited by Count Emil Dessewffy), *Pesti hírlap* ("Pesth Journal," edited by Kossuth), and the *Pesther Zeitung*, in German. Among the most celebrated journals which sprang up during the revolution were the *Közlöny* ("Organ"), the revolutionary *Moniteur*, and *Kossuth hírlapja* ("Kossuth's Journal"), edited by Bajza. Among the principal newspapers which have appeared in Hungary since the revolution are the *Budapesti napló* ("Buda-Pesth Diary"), *Vasárnapi újság* ("Sunday News"), edited by Pakh, and the *Pesther Lloyd*, in German. The movements of 1860 gave rise to a large number of new journals, all of a liberal character. The press of Bohemia, Transylvania, Croatia, and neighboring countries, having relapsed after its temporary activity during the revolutionary excitement of 1848-'9 into insignificance, also assumed a new importance at the close of 1860.—The first Turkish newspaper appeared in French in 1795, but the actual founder of journalism in Turkey was Alexandre Blacque, who established at Smyrna in 1825 the *Spectateur d'Orient*, which, under its subsequent title of *Courrier de Smyrne*, exerted considerable influence during the Greek revolution. The official journal of the government has appeared in French since 1831 under the title of *Moniteur Ottoman*, and in Turkish since 1832 under that of *Taquimi vagdi*. The leading Constantinople journals in 1861 are the *Journal de Constantinople* in French, and the *Djeridei ha-*

vadis in Turkish; beside which there are several other papers in French, Italian, modern Greek, and Armenian, published in various parts of the Ottoman empire, chiefly at Constantinople, Smyrna, Beyrout, Alexandria, and Cairo. A modern Syrian newspaper has been published by missionary enterprise since 1850 at Ooroomiah. The Armenians display more journalistic ability than most other oriental peoples, and have in 1861 over 80 daily and periodical journals, some of which are devoted to science and literature, published chiefly in Constantinople and Smyrna; Armenian journals have existed at various periods in Vienna, Venice, Transcaucasia, Calcutta, Madras, and Singapore, some of which are still in existence.—The origin of Greek newspapers dates from the establishment of national independence, and several appeared simultaneously in 1824 in different cities. The centre of Greek journalism is Athens. The number of periodicals published in Greece in 1861 is more than 100. Those best known abroad are the *Ελπίς* ("Hope") and *Αἰών* ("Age"), published in Athens, as well as the *Spéctateur d'Orient*, a semi-monthly journal published there in French since 1852. There are journals published at Nauplia, Patras, Syra, and in the Ionian islands; there are several publications in English and Italian as well as in Greek. A Greek newspaper was established in 1860 in London, and is actively supported there by Greek merchants and by English scholars.—Newspapers were established in Belgium before they were known in Great Britain, France, or Germany. The earliest appears to have been the *Nieuwe Tydinghen*, published at Antwerp by Abraham Verhoeven in 1605. No copy of this journal anterior to 1619 is now known to exist, and it is somewhat uncertain whether it was from the beginning a regular periodical. It was followed by the *Gazette extraordinaris Port-Tydinghen*, which was published between 1637 and 1644, and was the foundation of the *Gazette van Antwerpen*, which continued till 1827. At Brussels there were at least two newspapers in existence between 1637 and 1645. The *Annales politiques* of that city was a famous journal of the last century, and the Austrian government subscribed for 1,200 copies of it annually. It was so popular that a pirated edition was regularly printed and circulated. The most noted of the Belgian journals at the present day are the *Moniteur Belge*, the official paper, and the *Indépendance Belge*, an organ of the liberal party, both established at Brussels in 1831; the latter has about 9,000 subscribers. The independent newspapers of largest circulation are the *Echo de Bruxelles* and the *Journal de Belgique*, both published at Brussels. Holland has numerous newspapers, but none of much political importance. The principal ones are the *Allgemeene Handelsblad* of Amsterdam; the *Courant* of Haarlem; and the *Staats Courant* and the *Journal de la Haye*, both published at the Hague. Switzerland in 1849 had 77 German

newspapers, but of the number of those in the French language we have no account.—The earliest newspaper in Sweden was the *Ordinarie Port-Tidende*, established in 1643; but the journals had little political influence till 1830, when the *Argus* appeared at Stockholm. Since then the *Fäderneslandet* and the *Aftonbladet* have been the principal journals of the capital, the former conservative, the latter liberal, with at one time 5,000 subscribers. There is a newspaper published in every considerable town of the kingdom, and the total number in 1850 was 118. The Christiania *Intelligentmedler*, founded in 1768, is the oldest newspaper in Norway. *Der Constitutionelle* at Bergen is the organ of the government; and the *Morgenblad*, established at the same place in 1819, is the journal of the popular party. The oldest newspaper of Denmark is the *Berlingske Tidende*, which was first published in 1749 in the German language, though it now appears in Danish. Until 1830 Copenhagen had but two journals, and those of little influence. In 1849 the number of political papers in the kingdom was 86.—In China, a species of newspaper has existed at Peking for centuries under the title of *King Chau*, or court transcripts, which is commonly called by Europeans the "Peking Gazette." It is compiled from the papers presented before the general council of the empire, and constitutes the principal medium available to the people for ascertaining what is going on in the country. Every morning ample extracts from the papers decided upon or examined by the emperor, including his own orders and rescripts, are placarded upon boards in a court of the palace, and form the materials for the annals of government and the history of the empire. Couriers are despatched to all parts of China bearing copies of these papers to the high provincial officers. Anybody is permitted to print these documents without note or charge, and to sell them to the people. This "Gazette" is very generally read and talked about by the gentry and educated people in the cities. In the provinces thousands of persons find employment in copying and abridging it for those who cannot afford to buy the complete edition. In 1827 an English weekly newspaper, the "Canton Register," was established at Canton; and in 1836 a similar journal, the "Canton Press," made its appearance. At present the "North China Mail" at Shanghai, and the "China Mail" at Hong Kong, are the principal English newspapers in that quarter. In the island of Penang the "Prince of Wales Island Gazette" was founded in 1805, suspended for some years, and revived in 1838. At Singapore, the "Singapore Chronicle" was established in 1828; at the same place in 1860 there were two English newspapers, the "Free Press" and the "Straits Times," both with small circulation.—In India, a newspaper called "Hickings Gazette" was established at Calcutta in Jan. 1781; and in 1795 the Bengal *Hurkuru* made its appearance and

still continues, the oldest of the Indian newspapers. It became a daily in April, 1819. Until 1835, however, the press in India was restrained either by a censorship or by the right assumed by the East India company of deporting to Europe obnoxious editors, of whom the most notable examples were those of the American William Duane, editor of the "World" at Calcutta, who was transported to England in 1794, for an inflammatory address to the army, and afterward returned to America and became an influential editor and politician; and of the Englishman James Silk Buckingham, editor of the "Calcutta Journal," who was sent home in 1838. A law drafted by Macaulay, and enacted by Sir Charles Metcalfe as governor-general in 1835, removed all arbitrary restrictions upon the press. On the outbreak of the sepoy mutiny in 1857, an act was passed prohibiting the use of the press except under a license from the government; this act, however, was by its terms limited to one year from date. The leading English journals now in existence in Hindostan are the "Friend of India" at Serampore, the "Englishman" at Calcutta, the "Athenæum" and "Spectator" at Madras, the "Herald" at Bangalore, the "Times," "Telegraph," and "Gazette" at Bombay, the "Gazette" at Delhi, the "Observer" at Poonah, and the "Chronicle" at Lahore. These are all of limited circulation compared with the newspapers of Europe and America, none except the "Friend of India" exceeding 1,000 copies. At Calcutta and at some other cities there are newspapers in the native languages; in 1846 there were 8 of these at Calcutta alone.—The first newspaper in Australia was the "Sydney Gazette and New South Wales Advertiser," founded in 1803 by George Howe. At present (1861) a great number exist in the various colonies, of which the principal dailies are: at Melbourne, the "Argus," with a circulation of 28,000, the "Age," and the "Herald," which is the government paper; at Sydney, the "Herald" and the "Empire," with each a circulation of about 7,000. In New Zealand in 1858 there were 14 English newspapers, and one in the native or Maori language. There are several published in Tasmania or Van Diemen's Land, at Hobarton and Launceston, and also several in the colony of the Cape of Good Hope. The first newspaper in the latter colony was the "South African Commercial Advertiser," established in 1824.—In Spanish America, the first newspaper was founded in Chili in 1812; and in 1855 the total number of periodicals in Mexico, Central and South America, was 192, distributed as follows:

Mexico.....	80	Bolivia.....	2
Central America.....	3	Chili.....	14
Havana.....	7	Buenos Ayres.....	6
Porto Rico.....	8	La Plata.....	4
St. Domingo.....	4	Paraguay.....	2
New Granada.....	48	Montevideo.....	4
Venezuela.....	3	Brazil.....	83
Ecuador.....	3		
Peru.....	27	Total.....	192

Four of these periodicals were published in English, 5 in French, 1 in German, 29 in Portuguese, and the rest in Spanish. The population among whom they circulated may be estimated at about 30,000,000. In Mexico the oldest newspaper is *El siglo XIX.*, which is published daily and supports liberal principles. The newspapers of Central America and of St. Domingo or the Dominican republic are official in character, and have a very limited circulation. Those of Havana and Porto Rico are restrained by the government from political discussions, and their contents are chiefly commercial or literary. Of the 82 newspapers of Brazil, 7 are published in Rio Janeiro, 6 in Pernambuco, and 2 in Bahia; one is in French and one in German. The principal daily newspapers of Rio Janeiro are *El jornal do commercio*, *Diario do Rio*, and *Correio mercantil*. The Brazilian press is respectable and well conducted, and pays due attention to public affairs. In Chili, there are 2 daily newspapers in Valparaiso, 2 in Santiago, and 2 in Copiapo, of which the most important is *El Mercurio* at Valparaiso, which is ably conducted and has a circulation of 2,000 copies. The chief newspapers of Buenos Ayres are *El nacional*, *El orden*, *La cronica*, and an English journal, the "British Packet." The only newspapers of Peru that deserve notice are *El comercio* and *El heraldo*, both dailies of considerable circulation. The press of New Granada is the freest, the most active, and most numerous of any of the Spanish American republics. In Bogota, the capital, there are 10 newspapers, of which one is official, one religious, one literary, and the others political, 2 being conservative and 5 liberal. Those which have the largest circulation are *El porvenir*, *El Neo-Granadino*, and *El tiempo*, all of which are liberal.—In the present British American colonies the credit of establishing the earliest newspaper belongs to the island of Barbados, where Samuel Keimer founded the "Barbados Gazette" in 1731. Thirty-one years afterward, in 1762, appeared the "Barbados Mercury," which continued till 1845. In the other British West India islands newspapers were introduced as follows: Grenada, 1742; Antigua, 1748; St. Kitt's, 1748; Dominica, 1765; St. Vincent, 1784. In July of the latter year the "Bermuda Gazette" was founded. In Canada, the "Quebec Gazette" appeared in 1765, and the "Montreal Gazette" in 1775. In Nova Scotia, the "Halifax Gazette" appeared in 1751, but was not firmly established till 1760. In New Brunswick, 2 or 3 newspapers were published at St. John's in 1782.—The first newspaper in the United States was issued at Boston, Sept. 25, 1690. It immediately attracted the attention of the colonial legislature, which declared that its publication was contrary to law, and that it contained "reflections of a very high nature." The authorities probably prohibited the further publication, for a second number does not seem to

have been issued, and only one copy of No. 1 is known to be in existence, which is in the state paper office at London, and is a small sheet of 4 quarto pages, one of them blank. Its contents record passing occurrences, foreign and domestic. Richard Pierce was the printer and Benjamin Harris the publisher. In the same year Gov. Fletcher of New York caused a "London Gazette," containing intelligence of an engagement with the French, to be reprinted. On Monday, April 24, 1704, appeared the first number of the "Boston News Letter," a half sheet of paper 12 inches by 8, with two columns on each page. It was published and edited apparently by John Campbell, postmaster of Boston, a Scotchman and a bookseller. This journal continued to be issued weekly until 1776. It was followed by the "Boston Gazette," begun Dec. 21, 1719; and on the next day the "American Weekly Mercurie" was issued from the printing office of William Bradford at Philadelphia. On Aug. 18, 1721, James Franklin, elder brother of Benjamin Franklin, established at Boston the "New England Courant," which soon became involved in a violent controversy with the Rev. Increase Mather and other ministers on the subject of inoculation, which the clergy advocated, while the "Courant" denounced and ridiculed it. It also attacked the magistrates, and was unusually free in its remarks on public affairs. In 1722 the legislature interfered and issued an order forbidding James Franklin "to print or publish the 'New England Courant' or any other pamphlet or paper of the like nature, except it be first supervised by the secretary of this province;" a committee of the house having reported "that the tendency of said paper is to mock religion, and bring it into contempt, that the Holy Scriptures are therein profanely abused, that the reverend and faithful ministers of the gospel are injuriously reflected on, his majesty's government affronted, and the peace and good order of his majesty's subjects of this province disturbed by the said 'Courant.'" James Franklin's name was consequently taken from the paper, and that of Benjamin substituted. The latter was at the time but 16 years of age, and was an apprentice in the printing office. It was in the columns of the "Courant" that he began his literary career, and at this period he was one of the most frequent and pungent of its writers. Four years after the first publication of the "Courant," on Oct. 16, 1726, William Bradford, the founder of the "Mercurie" at Philadelphia, began the publication of the "New York Gazette," the first newspaper issued in that city. In 1764 there were 4 newspapers published in Boston, 2 in New York, 2 in Philadelphia, and the "Virginia Gazette" at Williamsburg, which was first issued in 1736 by William Parks. From 1764 to 1776 the number of journals increased considerably. In the latter year 7 were published in Massachusetts, one in New Hampshire, 2 in Rhode Island, 4 in Connecticut, 4 in

New York, 9 in Pennsylvania, 2 each in Maryland, Virginia, and North Carolina, 3 in South Carolina, and one in Georgia—in all, 37. These were all weeklies, with the exception of the "Advertiser" of Philadelphia, which was issued twice a week. In 1800 the number of newspapers in the United States had increased to 200, of which several were dailies, the first daily having been the "Pennsylvania Packet, or the General Advertiser," called afterward the "Daily Advertiser," which continued to be issued daily from 1784 till 1837. During the revolutionary struggle the principal journal in Boston was the "Gazette," which was established in April, 1755, and was the main organ of the patriots. It was published by Edes and Gill, and was at first a crown half sheet printed in two pages folio, but about 1760 it was enlarged and printed on a whole demy sheet. Its office of publication became the habitual resort of the most distinguished political writers on the American side, among them James Otis, John Hancock, Joseph Warren, Thomas Cushing, Josiah Quincy, jr., and John and Samuel Adams. Every measure of the government was examined and criticized in its columns by these able politicians with freedom and severity, and with a prodigious effect on the popular mind. "No press in the country," says Buckingham, "exerted a more powerful influence over the feelings, opinions, and conduct of the people." It was in this journal that John Adams wrote under the signature of Novanglus his celebrated series of papers in defence of the colonial cause, the first of which appeared in Jan. 1775, and they were continued every week till April 19 of the same year, when the outbreak of hostilities at Lexington and Concord rendered further argument needless. On the same side in politics was the "Massachusetts Spy," edited by the intrepid Isaiah Thomas, the historian of American printing, who founded the paper March 7, 1771, and removed it to Worcester in 1775, where it is still published. In New York, during the revolution, Rivington's "Royal Gazette," established in 1773, attained a circulation in its first year of 8,600, and was a zealous and powerful supporter of the royal cause. It was discontinued soon after the peace of 1783. In 1797 was established the "Commercial Advertiser," now the oldest of New York newspapers; and in 1801 the "Evening Post," which was founded by William Coleman, a lawyer from Massachusetts, and has always been remarkable for the ability of its conductors, among whom in the past was William Leggett, and at the present time (1861) are William C. Bryant and Parke Godwin. Mr. Bryant's connection with the "Post" began in 1826. About the same time that the "Evening Post" was established in New York, another journal of high character and influence, the "National Intelligencer," was founded at Washington by Samuel Harrison Smith. With this paper Mr. Joseph Gales became connected in 1807, and

continued its editor till his death in 1860. In 1812 he took into partnership his brother-in-law, Mr. William W. Seaton, by whom the journal is still edited. In Jan. 1818, it was issued as a daily. From 1800 to 1810 the number and circulation of American newspapers largely increased. By the census of the latter year it appeared that the number of journals was 359, of which 27 were dailies, and the total annual issue was 22,321,000 copies. In 1824 there were 11 daily newspapers in Philadelphia and 12 in New York, with a circulation varying from 1,000 to 4,000 copies. In 1828 the whole number had increased to 852, with a yearly issue of 68,117,796 copies. In 1830 the number was estimated at 1,000, one of which, the "Christian Advocate and Journal," a weekly Methodist paper, had in 1831 a circulation of 25,000 copies. The census of 1840 returned 1,631 newspapers, with a yearly issue of 195,838,673 copies; and in 1850 the number had reached to 2,800, with an annual circulation of 426,409,978 copies, or an average of 21.81 copies to each person in the population, and of 12.9 journals to every 100,000 inhabitants. The number of daily newspapers in 1850 was 254, with an average circulation of 3,200 copies each. No official statement of the number of journals in 1860 has yet been published, but there is reason to believe that the total does not much exceed that of 1850. The number of dailies in the large cities has been diminished by the absorption of the weaker ones by the stronger. In 1833 a "penny paper" called "The Sun" was established in New York by Benjamin H. Day. It was about 10 inches square, and being sold for one cent, grew rapidly into a circulation of 60,000 copies. The size was increased, and it is now a large and respectable journal, the only one of many rivals which has maintained itself as a penny paper. In 1835 Mr. James Gordon Bennett began the publication of the "New York Herald," at first as a penny paper, but afterward raised the price to two cents. Its circulation on Jan. 1, 1861, as stated by its publisher, was 93,840, and its average daily circulation during the month of January 85,308. On April 10, 1841, the "Tribune" was begun by Mr. Horace Greeley, and in Jan. 1861, had reached a circulation for the daily edition of 53,500, for the semi-weekly of 24,000, and for the weekly of 205,500, beside a special edition for California of 2,500. The "New York Times" was established in 1850 by Mr. Henry J. Raymond, and has a circulation of 50,000 daily, 25,000 weekly, and 12,000 semi-weekly. The total circulation of the New York dailies now exceeds 300,000 a day, while in 1835 it was not more than 10,000. The New York dailies formed a combination in 1855 and established the "Associated Press" company for collecting and distributing to the newspapers the latest news from all quarters by telegraph, at an annual expense of \$300,000. Some of these papers, however, expend for extra despatches as much as \$50,000 a year. Some of

the weekly papers, as "Harper's Weekly," "Frank Leslie's Illustrated Newspaper," and the "New York Ledger" of Robert Bonner, have an immense circulation, that of the last having at times exceeded 400,000 a week. The religious newspapers, of which the earliest was the "Boston Recorder" established in 1815, are published once a week, and their circulation is very large. The chief of these published in New York are the "Observer," the organ of the Old School Presbyterian denomination; the "Evangelist," New School Presbyterian; the "Independent," Congregationalist; the "Churchman," Episcopal; the "Advocate and Journal," Methodist; the "Examiner," Baptist; and the "Christian Inquirer," Unitarian. In most of the large cities of the Union German newspapers are published, some of which have an extensive circulation. In New York a French daily newspaper, the *Courrier des États Unis*, has long been maintained, and there are several French newspapers in New Orleans. There are also Welsh, Spanish, and Dutch journals. In St. Louis a Croatian newspaper has been published, and a Chinese one in San Francisco.

NEWSTEAD ABBEY, the family seat of Lord Byron, situated on the verge of Sherwood forest, 8½ m. W. from Nottingham. The building was originally a priory of black canons, founded in 1170 by Henry II., and at the dissolution of the monasteries was granted by Henry VIII. to Sir John Byron. It was then a fine specimen of the early Anglo-Gothic order of architecture, unsurpassed in elegance of composition and delicacy of execution, and "stood embosomed in a happy valley," the slopes of which were covered by the broad oaks of Sherwood forest. The new possessor converted a portion of the building into a dwelling; and his successors have from time to time altered, embellished, or added to it, until it presents a singular mingling of opposite styles of architecture, the restorations generally savoring "more of the baron than the monk." The 5th Lord Byron, great-uncle of the poet, and a stern and desperate character, pulled down a large part of the house, cut down extensive plantations, and in general did all he could to injure the estate, from some cause of irritation against his son and heir, who however died before him. The dilapidated appearance of the building upon the accession of George Gordon Byron, the 6th lord, is described in his lines beginning:

Through thy battlements, Newstead, the hollow winds
whistle;
Thou, the hall of my fathers, art gone to decay.

In 1817 Byron parted with Newstead to Col. Thomas Wildman, an old schoolfellow, for £180,000. The latter subsequently spent over £200,000 on the reparation of the property, which upon his demise in 1859 was put up at auction, the reserved price being £180,000. As the highest bid was but £121,000, the estate was bought in by Col. Wildman's representatives, in whose possession it now

remains. The most conspicuous feature of the abbey at the present day is the majestic front of the old church, adorned with lofty pinnacles and rich carvings. The refectory and cloisters are in excellent preservation, and "an exquisite small chapel" in the Gothic style is still used for religious purposes. In front of the building is a small lake fed by sedgy streams; the neighboring hills have lost much of their woodlands, and many are now clad with heather only. The place underwent great improvements after it passed into the hands of Col. Wildman, who preserved whatever relics of the poet he found there; and it is now probably in a better condition than at any time since it lost its monastic character.

NEWT, a name given in Great Britain to the tritons or aquatic salamanders, distinguished from the efts by the more granulated surface of the body. (See TARTOX.)

NEWTON, the name of counties in 5 of the United States. I. A central co. of Ga., bounded S. W. by South river, and intersected by Yellow and Ulcofauhachee rivers, all three uniting at its S. extremity to form the Ocmulgee; area, about 400 sq. m.; pop. in 1859, 14,241, of whom 6,234 were slaves. It has an undulating surface and a soil very fertile near the streams. The productions in 1850 were 463,130 bushels of Indian corn, 104,202 of sweet potatoes, 60,315 of oats, and 6,938 bales of cotton. There were 3 saw mills, 7 grist mills, 1 woollen and 1 cotton factory, 30 churches, and 478 pupils attending public schools. The Georgia railroad passes through the capital, Covington. II. A central co. of Miss., drained by the head branches of the Chickasawha river; area, about 550 sq. m.; pop. in 1850, 4,465 of whom 1,032 were slaves. The productions in 1850 were 165,186 bushels of Indian corn, 58,047 of sweet potatoes, 12,861 of oats, 1,474 bales of cotton, and 32,330 lbs. of rice. Capital, Decatur. III. A S. E. co. of Texas, separated from Louisiana by the Sabine river and drained by its branches; area, about 1,000 sq. m.; pop. in 1858, 2,578, of whom 755 were slaves. The surface is undulating toward the S. and somewhat hilly in the N. The soil of the bottom lands is highly productive, but much of the upland is poor and sandy. The productions in 1850 were 34,135 bushels of Indian corn, 19,890 of sweet potatoes, 152 bales of cotton, 14 hhds. of sugar, 23,570 lbs. of rice, and 10,218 of butter. Capital, Newton. IV. A N. W. co. of Ark., drained by the Buffalo fork of White river and its head branches; area, 900 sq. m.; pop. in 1854, 2,550, of whom 81 were slaves. It has a diversified surface, much of it still covered with forests, and a generally fertile soil. The productions in 1854 were 114,489 bushels of Indian corn, 7,510 of oats, and 3,965 of wheat. In 1850 there were 8 churches, and 180 pupils attending public schools. Capital, Jasper. V. A S. W. co. of Mo., bordering on Kansas and the Indian territory, drained by branches of the Neosho

river; area estimated at 750 sq. m.; pop. in 1856, 6,720, of whom 288 were slaves. The productions in 1850 were 192,210 bushels of Indian corn, 18,416 of wheat, 81,318 of oats, 7,062 lbs. of wool, and 43,011 of butter. There were 2 churches, and 278 pupils attending public schools. Capital, Neosho.

NEWTON, a township of Middlesex co., Mass., on a curve of the Charles river, which bounds it N., W., and S., and on the Boston and Worcester railroad, 8 m. from Boston; pop. in 1855, 6,768. The river has here two falls, supplying extensive water power, and at each fall there is a manufacturing village, the one called Newton Upper Falls and the other Newton Lower Falls. The other villages are Newton Corner, Newtonville, West Newton, Auburndale, and Newton Centre. The last is the seat of the Newton theological institution, founded by the Baptists in 1826; and the town contains several other educational institutions of considerable reputation. In 1855 there were 5 paper mills, 1 cotton mill producing to the value of \$100,000 yearly, and various other manufactories. In 1856 there were 12 churches, viz.: 3 Baptist, 6 Congregational, 2 Episcopal, and 1 Methodist.

NEWTON, GILBERT STUART, an English painter, born in Halifax, Nova Scotia, Nov. 2, 1795, died in Chelsea, England, Aug. 8, 1835. Upon the death of his father he removed in 1808 with his mother to Boston, of which city she was a native, and was instructed in painting by his maternal uncle, Gilbert Stuart. About 1816 he accompanied an elder brother who was engaged in commerce to Italy; and after studying a while at Florence and elsewhere, he repaired in 1817 to London and became a student in the royal academy. Here he formed an intimacy with Charles R. Leslie, then rising into eminence, and subsequently with Washington Irving, who, speaking of the career of the two artists, says: "Their advancement in skill and reputation, ever counselling, cheering, and honoring each other, had something in it peculiarly generous and praiseworthy." He early adopted a style founded on that of Watteau, but possessing more distinctive character and expression, and first attracted notice by his "Forsaken" and "Lover's Quarrel," from Molière's *Dépit amoureux*, which were engraved for the "Literary Souvenir" of 1826. Other works, distinguished alike by their humor and exquisite coloring, are "Shylock and Jessica," "Yorick and the Grisette," "The Abbot Boniface," "A Poet reading his Verses to an impatient Gallant," and "Macheath." In a different vein from these, but not less excellent, were his "Lear attended by Cordelia and the Physician," "The Vicar of Wakefield restoring Olivia to her Mother" (of which Leslie said: "I know nothing in the art more exquisitely conceived than the figure of Olivia"), and "Abelard in his Study," his last picture exhibited in the academy, of which he was elected a member in

1683. Most of these pictures have been well engraved. In 1682 he revisited the United States, and while there was married to a lady of Boston. Shortly after his return in 1683 he exhibited symptoms of mental aberration, which settled into confirmed insanity, and the last two years of his life were passed in a lunatic asylum at Chelsea. Many pleasant notices of him occur in the "Autobiographical Recollections" of Leslie, who says, in reference to the unfavorable impression which his friend sometimes made: "Newton, like Constantine, was misunderstood by those who did not know him thoroughly. I knew enough of him and of his actions to know that his heart was noble and his mind a pure one." As an artist he was distinguished, according to Irving, by "a coloring almost unrivalled, and a liveliness of fancy, a quickness of conception, and a facility and grace of execution, that spread a magic charm over his productions."

NEWTON, SIR ISAAC, an English philosopher, born in Woolsthorpe, Lincolnshire, Dec. 25, 1642, died in Kensington, a suburb of London, March 20, 1727. He was a posthumous and only child, and born, like Kepler, prematurely. He was descended, according to his own account, from Sir John Newton of Westby in Lincolnshire, and according to another from a Scotch family in East Lothian. When he was 3 years of age, his mother, having married again, gave him to the charge of his maternal grandmother. He went to school at Skillington and Stoke till his 12th year, when he was sent to the free school at Grantham, 6 miles from his native hamlet, taught by a Mr. Stokes. He ranked low in his classes till a quarrel with the boy who stood next above him roused his pride, when he applied himself with such resolution to his books that he at length stood at the head of the whole school. He was usually less interested in the sports of his schoolmates than in constructing little mechanical contrivances, in which he showed marked facility of imitation and invention. He was early fond of drawing, and covered the walls of the room where he lodged with excellent charcoal sketches of birds, beasts, men, ships, and mathematical figures. His apartment was also furnished with pictures drawn and framed by himself; and he was an adept at verse-making. Already during his residence at Grantham he was interested in the motions of the heavenly bodies. From several years' observations, he arranged a set of pins or gnomons upon the adjacent houses so as to mark the time of day by their shadows. The arrangement served as a sort of town clock, and was known as "Isaac's dial." On the outside wall of his house at Woolsthorpe there is still shown a sun dial which he must have carved there. There were formerly two, but the stone on which the other was cut was removed in 1644 and presented to the royal society. In 1656 his mother, now again a widow, took him from school to help in the management of the farm at Woolsthorpe, in-

tending him for a rustic life; but such was his passion for study, that he found little leisure to look after the economical concerns of the manor. His mother had the wisdom not to thwart his bent, and sent him back to Grantham, where, by the advice of his uncle, the Rev. W. Ayscough, he was fitted to enter Trinity college, Cambridge, in 1661. It does not appear that he showed a marked preëminence in the studies of the university; but this is owing, no doubt, to his indifference to public honors, and his love of studious seclusion, which are conspicuous throughout his life. He extended his studies beyond the prescribed routine in several directions. In the winter of the year in which he was elected scholar (1664), or earlier, he invented his binomial theorem, to which he had been led by investigations into the problem of the quadrature of the circle, and directed his attention to the subject of circles or halos around the moon, of which he subsequently gave the theory in his treatise on optics. In 1665 he took the degree of B.A., and probably in the same year invented fluxions.—At this period the thoughts of philosophers were strongly directed to the telescope. Huyghens had constructed instruments which revealed the rings and satellites of Saturn. Descartes had explained the theory of refraction, and had pointed out how glasses could be ground of such a shape as to unite parallel rays of light in a focus. Still these glasses had the great defect of giving a confused image, which was thought to be owing to imperfect manufacture, and Newton applied himself to grinding them with more accuracy. But he seems to have suspected that the defect lay deeper than the inaccuracy of the lens, and thereupon began to experiment with a ray of light. He soon came to the important conclusion "that light was not homogeneous, but composed of rays, some of which were more refrangible than others." This showed him that the defect in the lens of the refracting telescope was inherent and not accidental. He accordingly abandoned his attempts to improve that instrument, and devoted himself to the construction of a reflecting telescope, which James Gregory of Aberdeen, in view of the defects of the refracting medium, had already invented. While engaged on this the plague forced Newton to retire to Woolsthorpe (1666), and it was more than two years before he proceeded further in his researches. It was during his retreat at Woolsthorpe—whether in this or the previous year is uncertain—that he first conceived the identity of gravity with the force which holds the planets to their orbits, and made his first test calculations; but, starting with a false basis of facts, he failed to verify the happy conjecture (see GRAVITATION); and it was not till 1679 that we find him again at work upon the problem. On the cessation of the plague he returned to Cambridge, was made junior fellow in Oct. 1667, and senior fellow in March, 1668, and was graduated M.A. in July of the same year. In the autumn of 1668

he completed a reflecting telescope 6 inches in length, magnifying 40 times, which enabled him to see Jupiter's satellites and the phases of Venus. This was the first reflecting telescope ever directed to the heavens, for Gregory had never completed the instrument which he had invented. Compared with the much earlier refractors of Hevelius and Huyghens, however, this was a small and ill-made instrument. In consequence of interruptions, Newton did not resume his labors in the construction of reflectors till the autumn of 1671, when he made another, which was sent up in December "for his majesty's perusal." It is carefully preserved in the library of the royal society of London. Constructing telescopes, however, was rather incidental to Newton's labors than the object of them, and he never resumed it again. His mind appears to have been much occupied at this time and for many years afterward with "chemical studies and practices." His celebrated letter (1669) of advice to Mr. Aston, who was about to set out for a tour of the continent, reveals a strong belief in the doctrines of alchemy; and he certainly pursued his experiments to a late period of his life in the hope of effecting some valuable transmutations. "About 6 weeks at spring and 6 at y^e fall," says Humphrey Newton, who was his amanuensis during 1684-'9, "fire in his laboratory scarcely went out. . . . He made very little use of his chymicals, y^e crucibles excepted, in which he fused his metals."—In 1669 he succeeded Dr. Barrow in the Lucasian chair of mathematics at Cambridge, and during that and the next year spent considerable time in writing notes for a Latin translation of Kinckhuysen's algebra. At the same time the fluxionary calculus occupied his thoughts. In 1669-'72 he delivered a course of lectures on optics in the university, and from time to time communicated to the royal society the results of his researches on light and colors. The reception of the new doctrine of the compound nature of light was very stormy, and involved Newton in a long and acrimonious controversy both at home and abroad. Of his disputants, Dr. Hooke was the most intractable, the bitterest, and perhaps, excepting Huyghens, the ablest. The course of the controversy is instructive. Newton considered light to consist of material particles. Hooke believed it to result from a series of undulations of an elastic medium pervading all bodies. With this theory, which Huyghens maintained in common with Hooke, Newton's alleged discovery seemed incompatible, and was accordingly strenuously resisted. On the other side we see Newton himself rejecting Huyghens's beautiful law of double refraction in Iceland spar, "founded on the finest experimental analysis of the phenomena," because it was presented as a corollary of the undulatory theory. Hooke in the one case, and Newton in the other, failed alike to see, or refused to admit, that the principle in question was true or false independently of what light

is, or how it is propagated. It is remarkable that Newton should have missed, in the course of his optical experiments and the controversy which followed, the discovery of the different dispersive powers of different bodies. The opinion that all bodies produce spectra of equal length under the same angle of refraction, though "unsupported by experiments," observes Brewster, "and not even sustained by any theoretical views, seems to have been impressed upon his mind with all the force of an axiom; and when, under the influence of this blind conviction, he pronounced the improvement of the refracting telescope to be desperate, he checked for a long time the progress of this branch of science, and furnished to future philosophers a lesson which cannot be too deeply studied." From 1671 to 1676 his optical researches and the disputes in which they involved him seem to have occupied most of his time. How distasteful these disputes were to him may be gathered from a letter he wrote to Leibnitz, dated Dec. 9, 1675, in which he says: "I was so persecuted with discussions arising out of my theory of light, that I blamed my own imprudence for parting with so substantial a blessing as my quiet to run after a shadow." Nearly a year later he writes: "I see I have made myself a slave to philosophy." Once free of controversy, "I will bid adieu to philosophy eternally, excepting what I do for my private satisfaction, or leave to come out after me." He appears at this time to have thought of studying law, for he found "mathematical speculations at least dry if not somewhat barren." He had already in 1670 written: "I see not what there is desirable in public esteem, were I able to acquire and maintain it. It would perhaps increase my acquaintance, the thing which I chiefly study to decline." In Jan. 1672, he was elected fellow of the royal society; but offered his resignation in March, 1673, on the ground of being unable to attend the meetings, in consequence of the distance of his residence. He had a prospect at this time of pecuniary trouble from the loss, in due course of things, of his fellowship in the university, by his being appointed to the Lucasian chair; and it is likely that this prospect had something to do with his disposition to resign, for we find the society nearly two years later excusing him with others from the payment of the usual due of one shilling a week. Baily says, however: "It seems to have been no uncommon event for the society, in the early years of its existence, to remit the arrears of members, either on application from the members themselves, or on account of some other circumstances with which we are now unacquainted." The crown, however, came to his relief in 1675, by issuing a patent allowing the Lucasian professor to hold a fellowship without being obliged to go into orders. An interesting document in Newton's handwriting, entitled "A Scheme for establishing the Royal Society," has been brought to light by Sir

David Brewster. He probably drew it up at this time. His desire, it seems, was to convert the royal society into an institution like the academy of sciences in Paris. In Dec. 1675, he sent to the society his "Hypothesis explaining the Properties of Light," reprinted in the "Philosophical Magazine," Sept. 1846; and his "Explanation of the Colors of Thin Plates and of Natural Bodies," which Brewster says "is perhaps the loftiest of all his speculations." The phenomena of colors he ascribes to a supposed property of light which he calls "fits of easy reflection and transmission." The theory is that every particle of light, from its first discharge from a luminous body, possesses, at equally distant intervals, dispositions to be reflected from and transmitted through the surfaces of bodies upon which it is incident. This appears to have been his last communication to the society on optical subjects. His disputes with Hooke led him to resolve not to publish his optical discoveries during the lifetime of his rival; accordingly it was not till 1704, the year after Hooke's death, that his great work on "Optics" appeared. In this work he omits to give Hooke credit for certain observations, which in an hour of friendly intercourse, in his beautiful letter to him of Feb. 5, 1675-6, he had thus handsomely acknowledged: "If I have seen further than others, it is by standing on the shoulders of giants" (Descartes, Hooke, and others). In the preface he says: "Part of the ensuing discourse about light was written at the desire of some gentlemen of the royal society in 1675, . . . and the rest was added about 12 years after to complete the theory, except the 8d book and the last proposition of the 2d, which were since put together out of scattered papers." From 1673 to 1688 he delivered at the university, as Lucasian professor, lectures on arithmetic and algebra. These Mr. Whiston published in Latin in 1707, against Newton's wishes, it is said, on account of their being an unfinished work. A second edition was published in 1712 with improvements by the author, and they were translated into English soon after by Mr. Raphson. Maclaurin's algebra appears to have been drawn up as an annotation of this. Presentation copies of his optical and algebraical lectures, the latter in his own handwriting, are in the library of Cambridge university. In 1676 we find him publicly interesting himself in the raising of fruit trees. He edited the 8d Cambridge edition of Varenus's geography (1681).—In 1679 Newton's attention was recalled to the subject of universal gravitation by a letter from Hooke. This philosopher "had illustrated as early as 1666," observes Mr. Grant in his "History of Physical Astronomy," "by means of a beautiful experiment, the motion of a body revolving in an ellipse under the influence of a force directed continually to the centre. And in his letter to Newton on the occasion above referred to, he declared that if gravity decreased according to the reciprocal of the square of the distance, the

path of a projectile would be an ellipse having the centre of the earth in the focus." Newton had hitherto confined his researches to bodies revolving in circular orbits. He now addressed himself to the vastly more difficult problem of orbits of variable curvature, and demonstrated the mathematical necessity of the 3 laws of Kepler as applied to the motion of a body projected in free space, and acted upon continually by a force directed toward the focus. We shall see presently how Halley's failure to solve this very problem led to the composition of the *Principia*. Notwithstanding the satisfactory nature of these researches, Newton could not consider the law of gravitation established so long as the serious discrepancy found in his calculations upon the moon remained unaccounted for. The explanation was soon to be furnished. In 1682, hearing of a new measurement of a degree of the meridian by Picard, the French astronomer, which differed materially from the commonly received estimate, he was led to go over the calculation again on the basis of the new measure. The result, this time, was in exact agreement with observation. The foundation being thus firmly laid, he proceeded to build up a complete demonstration of the laws of the celestial motions. He perceived that the earth, by its axial rotation and the mutual attraction of the particles of matter composing its mass, must be flattened at the poles, and he determined the amount of this flattening. He showed that the spheroidal figure of the earth, combined with its diurnal motion, would cause the weights of bodies at the surface to vary in different latitudes; and this result of pure theory explained a singular fact first noticed by Richer, the French astronomer, who had found in 1672 that a clock regulated to mean time of Paris lost 2m. 28s. daily at Cayenne, within 5° of the equator. This led him to an explanation of the precession of the equinoxes. Kepler and others before him had spoken of an attraction of the waters of the earth by the moon. Newton explained the tides. He saw that the masses of the planetary bodies could be determined by observing the effects of their mutual attraction, and that from this cause their several motions would be disturbed. Thus he was conducted to an elucidation of the intricate subject of the moon's motions, which had long been a stumbling-block to astronomers. He deduced theoretically the two lunar inequalities known as the variation and the annual equation, and also the progression of the apogee and the regression of the nodes, though it was reserved for the mathematicians of the next century to complete the lunar theory. It is not known that he made any public announcement of his discoveries before Feb. 1685, when he sent to the royal society a paper containing his early researches on centripetal forces; nor indeed does it appear that up to this time he had developed his thoughts beyond the substance of this brief essay. Halley had endeavored in 1684 to calculate the law of

the solar force directed to the planets moving in elliptical orbits, this force being subject to continual variation. Failing, he had applied to his friends in London for assistance. Sir Christopher Wren plainly told him he had given much thought to the problem, but could make no impression upon it. Hooke asserted that he had solved it, but refused to furnish his demonstration. Halley then consulted Newton, and, finding to his delight that he had gone over the whole ground, induced him to communicate to the royal society the paper already alluded to. In April, 1685, he had entered seriously upon the composition of the *Principia*. Mr. Rigaud, in his "Historical Essay on the first Publication of the *Principia*" (Oxford, 1888, p. 25), has remarked in reference to this fact, that the *Principia* was not a protracted compilation from memoranda which might have been written down under the impression of different trains of thought. It had the advantage of being composed by one continued effort, during which the mutual bearing of all the several parts was vividly presented to the author's mind. Pemberton, in his preface to his "View of Sir Isaac Newton's Philosophy," states that the *Principia* was composed in the space of a year and a half. While engaged in writing the 2d and 3d books (April, 1687), he was called from his seclusion to act as one of the delegates appointed to defend the university against the attacks of King James II. upon its privileges. His Lucasian lectures at this time were not attractive to the students. According to the testimony of his amanuensis, Humphrey Newton: "So few went to hear, and fewer that understood him, that oftentimes he did in a manner, for want of hearers, read to the walls." On the presentation of Newton's paper to the royal society, Hooke raised a violent reclamation relative to the asserted discovery of the law of gravitation. He had as early as 1666 arrived at very accurate notions of centripetal forces. He had published in 1674 a work entitled "An Attempt to prove the Motion of Earth from Observations," in which, as Mr. Grant observes, he describes the general nature of gravity with remarkable clearness and accuracy. (There is a Latin translation of this work, printed in 1679.) But he had not attempted to compute the law of the variation of the force at different distances from the centre, which, as applied to the elliptical orbits of the planets, was the very problem which had baffled Halley and Wren, and which Newton had solved. The pretensions of Hooke called forth from Newton a long and interesting letter, dated June 20, 1686, in which he recounts the progress of his researches, and intimates his resolution to suppress the 3d book of his work rather than have his peace of mind disturbed by a controversy with envious rivals. By Halley's persuasion, however, Newton consented to let the whole appear, and as a compromise prefaced the scholium to the 4th proposition of the 1st book with the remark that Wren, Hooke, and

Halley had all found, by means of the relation between the periodic times and the distances, that the force which retains the celestial bodies in their orbits varies according to the inverse square of the distance. In April, 1686, the 1st book of the *Principia* was exhibited at the royal society, and in June Halley undertook the publication of it at his own expense, although it involved him in considerable pecuniary risk. About midsummer of the next year the work appeared from the press. The number of copies printed is not known. The original price seems to have been 10s. It is divided into 3 books. The 1st treats of motion in free space; the 2d treats chiefly of resisted motion; and the 3d deduces from these the system of the world. There is a copy of the original edition (4to.) in the Astor library, New York. It bears the following title page: *Philosophiæ Naturalis Principia Mathematica. Imprimatur Julii 5, 1686. Londini, 1687.* The doctrines of the *Principia*, like all discoveries which tend to overthrow cherished opinions, were hotly combated for many years. The philosophy of Descartes, which the Newtonian theories at length supplanted, was predominant throughout Europe; and such was the disfavor which the Newtonian philosophy met with everywhere on the continent, that, according to the remark of Voltaire, Newton had not at the time of his death above 20 followers out of England, though the *Principia* had then been 40 years before the world. "The language of the French mathematicians," observes the author of the "History of the Inductive Sciences," "is Cartesian for almost half a century after the publication of the *Principia* of Newton." "The profound and intricate reasoning which Newton was compelled to adopt," says Mr. Grant, "formed a serious impediment to the early dissemination of his doctrines." The British universities, however, early introduced the Newtonian philosophy as a subject of study. The university of St. Andrew's in Scotland took the lead in 1690, followed by Cambridge in 1699, and by Oxford in 1704. Dr. Bentley made the new principles the basis of a theological argument in the Boyle lectures preached in London in 1692-'8. After the publication of the *Principia*, Newton was content to extend and develop the principles of his philosophy without advancing into any new fields of science; and even these developments appear to have been based for the most part on experiments and observations previously made. He was elected to represent the university in parliament in 1689, and again in 1701; and though he was rejected in 1705, those who opposed him acknowledged him to be "the glory of the university," but considered that he was sent to "tempt them from their duty by the great and just veneration they had for him." In the spring of 1689, during his residence in London, in attendance at parliament, he became acquainted with John Locke, who in the year of the publication of the *Principia*

had completed his "Essay on the Human Understanding." A firm friendship grew up between these great men, unbroken till the death of Locke in 1704. During the sitting of parliament Newton was called from London to attend the death-bed of his mother (1689). In the summer of the same year he made the acquaintance of Huyghens, who was on a visit to London. In 1690 Locke and others of his friends tried in vain to procure for him a lucrative employment under government. Their failure touched him keenly. On the dissolution of parliament he resumed his philosophical and mathematical studies at Cambridge. After this his health became much impaired. In Dec. 1692, and Jan. and Feb. 1693, he wrote the four celebrated letters to Dr. Bentley on the existence of a Deity. Biot, in his memoir of Newton, published in the *Biographie universelle* in 1822, brings to light a MS. of Huyghens, which is employed to prove that Newton was suffering under derangement of mind at this time. Though the low state of his health gives color to Biot's startling statement, the argument does not appear to be sufficient. He was greatly affected about the beginning of 1692 by the loss of valuable MSS., which were consumed in his study by the upsetting of a candle while he was away at chapel. "Every one," remarks Mr. Abraham Pryme, who was a student in the university at the time, "thought he would have run mad; he was so troubled thereat, that he was not himself for a month after." The notable story of his little dog Diamond having occasioned the mischief, and of Newton's remarkable equanimity on seeing what had happened, Brewster considers a fiction. During this and the following year his health continued poor, and he certainly fell into a state of melancholy, though there is no direct evidence that his reason was unseated. A rumor went abroad however to that effect, and we find Leibnitz congratulating Huyghens, in a letter of June 22, 1694, on Newton's recovery. In a letter to Pepys, dated Sept. 18, 1693, and one to Locke about the same time, there are evidences of loss of judgment. Pepys at any rate says of his letter, it was "so surprising to me for the inconsistency of every part of it as to put me into great disorder by it, lest it should arise from that which of all mankind I should least dread from him and most lament for—I mean a discomposure in head or mind, or both." A fortnight after this letter was written, Newton told a common friend "that he had writ a very odd letter to Pepys at which he was much concerned," adding "that it was in a distemper that much seized his head, and that kept him awake for above 5 nights together." Not many days after his painful letter to Locke was written he wrote again with child-like simplicity and tenderness, asking to be forgiven for thinking ill of him, and subscribing himself: "Your most humble and unfortunate servant." The tone of Locke's noble reply to this (Oct. 5,

1693) plainly shows that he did not attribute his friend's mistakes to mental alienation.—About this time began the celebrated quarrel between Newton and Flamsteed, the astronomer royal, which was only terminated by Flamsteed's death (1719). They had been on terms of cordial intimacy till 1696, when a coolness began to spring up. Newton was engaged on his lunar theory, and required observations of the moon's places. Flamsteed, who at his own expense had put himself in possession of the proper instruments, was the only one who could furnish the observations. They were supplied, though not as promptly as Newton wished. Complaint followed, with little outbreaks of temper on both sides. Newton was at the summit of his fame, and Flamsteed saw the vast importance of his own labors, then unappreciated, but since fully allowed. Halley, devoted to Newton, doubtless jealous of Flamsteed, and wishing to supplant him, embittered the difference, if indeed it was not primarily his instigation that kept the quarrel alive. There seems to have been on both sides a cordial animosity, which neither Newton's habitual forbearance, equanimity, and love of peace, nor Flamsteed's sincere piety, could prevent from bursting out afresh on every occasion. The quarrel culminated in the publication, under Halley's name, of Flamsteed's celestial observations, which Halley had mutilated. This act, for which no sufficient excuse has been adduced, roused Flamsteed's indignation; and at a subsequent meeting of the parties, when Flamsteed declared that he had been robbed of his labors, Newton was provoked into the use of unseemly epithets toward him, "of which 'puppy' was the least." Three fourths of the edition afterward falling into Flamsteed's possession, he burned it, "as a sacrifice to heavenly truth." When we consider the extraordinary homage which was everywhere rendered to Newton, it is not surprising that he should have resented Flamsteed's refusal to pay him deference; nor, when we consider Flamsteed's hot temper, and the wrongs or supposed wrongs under which he smarted, can we blame him for want of respect toward his illustrious contemporary.—Through the patronage of Charles Montague, chancellor of the exchequer, and afterward earl of Halifax, Newton received in 1695 the appointment of warden of the mint, worth between £500 and £600 a year; and in 1699 he was promoted to the mastership of the mint, worth £1,200 to £1,500, which office he held during the rest of his life. In this situation his chemical knowledge was of great use; and in effecting the recoinage which was completed toward the close of 1699, his services were so highly appreciated that the chancellor of the exchequer declared that he could not have carried it on without his assistance. On his promotion he appointed Mr. Whiston to be his deputy at Cambridge, with the full profits of the place; and in 1701 he resigned the chair. In 1699 he was elected foreign associate of the

academy of sciences at Paris. He was chosen president of the royal society in 1708, and annually reelected during his life. In 1705 he was knighted by Queen Anne. In 1713 he communicated a paper to the royal society on the different kinds of years in use among the nations of antiquity; it was published in the "Gentleman's Magazine" for Jan. 1755, and the original is in the British museum. In 1717 he prepared two reports on the state of the coinage, which were laid before the houses of parliament. They were followed by a proclamation in Dec. 1717, reducing the value of guineas from 21s. 6d. to 21s.—In 1705 began the famous dispute with Leibnitz. Newton and Leibnitz, it is now clear, were both original inventors of the infinitesimal analysis, Newton being the earlier. Leibnitz, however, published his method in 1684, while Newton's did not appear till 20 years later. The geometry of the former spread rapidly over Europe; he was considered as the sole inventor, and Newton, in the first edition of the *Principia*, acknowledged his claims as an independent inventor. In 1699 a remark was dropped in the royal society casting suspicion upon the originality of Leibnitz's discovery. Leibnitz replied in the *Leipsic Journal* without asperity, asserting his claim. On Jan. 1, 1705, the same publication criticized with marked severity Newton's "Quadrature of Curves," then lately published, in which the method of fluxions was for the first time announced to the world, asserting in effect that the fluxionary method was not an original discovery. Newton and his friends were justly indignant, and Keill, an astronomer, undertook his defence, but was betrayed into doing similar injustice to Leibnitz, charging him in effect with having borrowed his calculus from hints thrown out by Newton. Leibnitz appealed to the royal society, which appointed a commission in the premises. Their report, which vindicates Newton's claims, forms what is called the *Commercium Epistolicum* (1712); for the contents of which, as also of a 2d edition with a review entitled *Recessio* (1722), Newton was himself fully responsible. In a new edition, edited by MM. Biot and Lefort (Paris, 4to., 1856), this report is shown to be in many points unfair. In 1718 John Bernoulli entered the quarrel with the declaration: "There is no reason to believe that the fluxionary calculus was invented before the differential." An issue so manifestly false shows not only the spirit of the continental party, but also, since Leibnitz allowed at least the statement to pass uncorrected, what must have been their provocation. The dissension continued without abatement up to Leibnitz's death (1716). Nor did Newton stop there. He published soon after what Biot characterizes as a "bitter refutation." In the 1st edition of the *Principia* (book ii., scholium to lemma 2) justice was done to Leibnitz's claim. In the 8d edition (1725) another scholium is substituted, in which Leibnitz's name is not mentioned.—

During his residence at Cambridge Newton was in the habit, as he expresses it, "of refreshing himself with history and chronology when he was weary with other studies." Hence grew up a system of chronology, which, however, was very imperfect and only existed in separate papers till the princess of Wales (afterward queen consort of George II.), who enjoyed the privilege of his conversation during the latter part of his life, requested a copy of it for her private use. The MS. after some years was printed in Paris (1725) surreptitiously, and involved Newton in an annoying controversy, in consequence of which he was induced to prepare a larger work which was interrupted by his death. It appeared toward the end of 1727, under the title, "The Chronology of Ancient Kingdoms amended, to which is prefixed a Short Chronicle from the first Memory of Things in Europe to the Conquest of Persia by Alexander the Great." His system was based on the astronomical observations of the ancients.—Previous to 1692 Newton was known by the appellation of an "excellent divine." It is therefore probable that his posthumous papers on religious subjects were composed in the prime of life, at Cambridge. His "Observations on the Prophecies of Daniel and the Apocalypse of St. John" appeared in London in 1733 (4to.). His "Historical Account of two Notable Corruptions of Scripture," mainly composed prior to 1690, but finished in that year, was first published in London in 1754, under the erroneous title of "Two Letters from Sir Isaac Newton to M. Le Clerc." In some catalogues of Newton's works another edition is mentioned, entitled "Two Letters to Mr. Clarke, late Divinity Professor of the Remonstrants in Holland" (1734). It appears to have been first published entire in Horsley's edition of Newton's works, under the title, "Historical Account of two Notable Corruptions of Scripture, in a Letter to a Friend." That friend was probably Locke. In this work he considers the two noted texts, 1 John v. 7, and 1 Tim. iii. 16. The former he attempts to prove spurious, and the latter he considers a false reading. There is no doubt that Newton was hostile to the doctrine of the Trinity. Indeed, the publication of several of his private papers in Sir D. Brewster's memoir places the fact of his entertaining Arian opinions beyond question. About the beginning of 1691 Locke contemplated going to Holland, and Newton sent him the above tract in strict confidence, requesting him to take it with him and procure its translation and publication in French, anonymously, as is evident; the object being apparently to ascertain the judgment of biblical critics before bringing it out under his own name in English. Locke abandoned his intention of visiting Holland, but sent the MS. to his friend Le Clerc in that country, who kept it in his possession till January of the next year, when he informed Locke that he was about to publish it in Latin. Newton, hearing of this became alarmed at the risk of detection,

and stopped the publication. At his death he left many MSS. on religious subjects, which have never been published. Beside a Latin dissertation on the sacred cubit of the Jews, printed in 1787 among the miscellaneous works of Mr. John Greaves, Newton's only other published religious writings are the four celebrated letters addressed to Dr. Bentley, first printed in 1756. They are directed against atheism, and aim to show that matter could never have arrayed itself in its present forms without a divine power being impressed upon it. Except a short tract on the nature of acids, his only chemical paper is one printed in the "Philosophical Transactions" for March and April, 1701 (pp. 824-829), under the title of *Scala Graduum Caloris*. It contains a comparative scale of temperatures, from that of melting ice to that of a small kitchen coal fire. To the 2d English edition of the "Optics" are appended a number of queries, the 18th and 24th of which contain his opinions in favor of the existence of an elastic ether diffused through all space, "much subtler than air." In Mr. Turner's "Collections for the History of Grantham" is given "a remarkable and curious conversation between Sir Isaac and Mr. Conduitt," his nephew-in-law, in which he speculates about planetary bodies having issued from the sun, and returning again at length to replenish its fires.—During the last 20 years of his life, which he spent in London, the charge of his domestic concerns devolved upon his niece, Mrs. Catharine Conduitt. For 2 or 3 years prior to 1725 he had been a good deal troubled with a disorder of the bladder, accompanied with cough and gout. In January of that year he was seized with violent cough and inflammation of the lungs, in consequence of which he removed his residence to Kensington, where his health improved. From this time the duties of his office at the mint were discharged by Mr. Conduitt. On Feb. 28, 1727, he went to London to preside at a meeting of the royal society, and became greatly fatigued. His old complaint returned with increased violence, and soon proved fatal. He was buried with great pomp in Westminster abbey, and his relatives devoted £500 for the purpose of a monument, which was erected in 1731. Though he had accumulated a personal estate worth at his death £32,000, he does not appear to have lived narrowly. Brewster states that he lived in London "in very handsome style, and kept his carriage with an establishment of 8 male and 3 female servants. . . . His generosity and charity had no bounds, and he used to remark that they who gave away nothing till they died, never gave at all." To his relatives in particular he was lavish. He was of medium stature, and in the latter part of his life inclined to corpulency. In old age he had a fine head of hair, as white as silver, without any baldness. He never wore spectacles, and it is stated never lost more than one tooth to the day of his death. Bishop At-

terbury, speaking of the last 20 years of his life, says: "He had something languid in his look and manner, which did not raise any great expectation in those who did not know him." "He spoke very little in company," observes Mr. Thomas Hearne, "so that his conversation was not agreeable." Though impatient of opposition and stupidity, he appears to have had no overweening opinion of himself. Alluding to his discoveries in a letter to Dr. Bentley, he says: "If I have done the public any service this way, it is due to nothing but industry and patient thought." When asked how he arrived at his discoveries, he replied: "I keep the subject constantly before me, and wait till the first dawns open slowly by little and little into a full and clear light." Thus was produced the *Principia*, to which Laplace assigns "a preëminence above all the other productions of the human intellect." The house in which Newton was born was purchased in 1858 by Miss Charlwood of Grantham, to be pulled down, that a scientific college might be erected on its site. His statue was inaugurated at Grantham, Sept. 21, 1858. His dwelling house, with an observatory which he built on the top, still remains in St. Martin's street, London, and is a place of scientific pilgrimage.—Beside the 1st edition of the *Principia* above noticed, a 2d was published at Cambridge in 1713, under the superintendence of Cotes, whose correspondence with Newton at the time has been published (London, 1850), under the editorship of Mr. Edleston. A 3d edition appeared in London in 1726 (4to.), edited by Pemberton; a 4th in 1729 (3 vols. 8vo., London), Englished by Motte; and a 5th in 1780 (2 vols. 8vo., London). Several editions have been published on the continent, the most famous of which is the Jesuits' edition (4 vols. 4to., Geneva, 1789-'42), republished in Glasgow under the editorship of Wright (4 vols. 8vo., 1822). A Latin translation of the "Optics," by Dr. Clarke, appeared in 1706 (4to., London), for which Newton presented the translator with £500. Many other editions have been published. Of the "Universal Arithmetic" there are several editions, both English and continental. The "Optical Lectures" appeared in London in 1728; "Fluxions," in English, with a commentary, in 1736. His principal works were collected and published by Bishop Horaley (5 vols. 4to., London, 1779-'85). His communications to the royal society are comprised in vols. vii. to xi. of the "Transactions."—See Sir David Brewster's "Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton" (2 vols. 8vo., 1855), and the other works cited.

NEWTON, JOHN, an English clergyman, born in London in July, 1725, died there, Dec. 21, 1807. After attending school at Stratford in Essex from his 8th to his 10th year, he accompanied his father, who was master of a ship, on a voyage to the Mediterranean, and subsequently made several trips. In his 19th year

he was seized by a press gang and taken on board the Harwich man-of-war, where however, through the influence of his father, he was made a midshipman. While the ship lay at Plymouth he deserted, but was soon caught, flogged, and degraded, and afterward treated with such severity that he willingly exchanged into an African trader off Madeira. This ship he left at Sierra Leone, and hired himself out as a laborer to a slave trader in the island of Benancoes; and there he remained till 1747. In this year an English captain arrived at Sierra Leone, commissioned by his father to bring him back; but nothing but the recollection of Mary Catlett, a Kentish girl to whom he had become attached before he left England, induced him to return. On the homeward voyage the perils to which he was subjected revived the religious impressions which he had early received from his mother. In 1750 he married Miss Catlett. Shortly afterward he commanded a Liverpool slave ship, was engaged in that business 4 years, and confesses that, during all the time he was in it, "he never had the least scruples as to its lawfulness." But growing disgusted with the occupation, he succeeded in obtaining, in Aug. 1755, the situation of surveyor of the port of Liverpool. While in Africa he had studied Euclid, and during his voyages had taught himself Latin; and he now devoted his time to acquiring the Greek and Hebrew. He engaged zealously in the religious movement originated by Wesley and Whitefield, and in 1758 applied to the archbishop of York for holy orders, but was refused on the ground of irregularity. In April, 1764, however, he was ordained by the bishop of Lincoln and appointed curate of Olney in Buckinghamshire, and shortly afterward was induced to publish an autobiography, entitled "An Authentic Narrative of some Remarkable and Interesting Particulars in the Life of the Rev. John Newton." At Olney he remained nearly 16 years, forming a very close friendship with the poet Cowper, in conjunction with whom he wrote the "Olney Hymns." In 1779 he was presented with the rectory of the united parishes of St. Mary Woolnoth and St. Mary Woolchurch Haw, Lombard street, London, where he remained till his death, preaching three times a week even when more than 80 years old. To all entreaties to stop, he replied: "What! shall the old African blasphemer stop while he can speak?" In doctrinal opinions he was a Calvinist, and was a prominent leader in the so called evangelical party in the church of England. Among his works may be mentioned a volume of "Six Discourses" (1760); a series of "Letters on Religion" (1762), under the signatures of Omicron and Vigil; "Cardiphonia;" and a "Review of Ecclesiastical History" (8vo., 1770), beside numerous sermons and tracts. A collected edition of his works was published in 1816 (6 vols. 8vo., London). His life was written by the Rev. Richard Cecil (London, 1808).

NEWTON, ROBERT, D.D., a Scottish clergyman, born Sept. 8, 1780, died April 30, 1854. In early life he joined the Wesleyan church and became a preacher. In 1808 he was appointed to the Glasgow circuit, where he attended the lectures in the university on divinity and philosophy. He was selected by the Rev. Joseph Benson, president of the conference, to deliver a series of sermons before that body at its annual meeting, and fulfilled the appointment to the entire satisfaction of the conference. In 1812 he became known in London as a speaker at public meetings, particularly in behalf of the British and foreign Bible society. From London he was removed to Wakefield, and thence to Liverpool. He was appointed secretary of the conference, and subsequently president. At the centenary conference held in Liverpool in 1839, he was appointed delegate to the general conference of the Methodist Episcopal church of the United States. His first sermon in America was delivered in New York, April 26, 1840; and during the whole time of his stay he attracted large crowds to his ministry. His first appointment in Baltimore, where the general conference was held, created such an excitement that long before the hour of service the church was crowded to excess, and the streets around were filled with people anxious to hear him. Finding no church large enough to contain his audience, permission was granted him to preach in Monument square, where he was listened to by 15,000 people. He subsequently preached in the hall of the house of representatives at Washington. One of his most effective addresses was delivered in the Tabernacle, New York, at the anniversary meeting of the American Bible society in 1840.

NEWTON, THOMAS, an English prelate, born in Lichfield, Jan. 1, 1704, died in 1782. He was graduated at Trinity college, Cambridge, took orders in 1729, received the curacy of St. George's, Hanover square, London, and afterward that of Grosvenor chapel, and in 1744 was presented by the earl of Bath to the rectory of St. Mary-le-Bow. He was chosen in 1747 lecturer of St. George's, Hanover square. In 1761 he became bishop of Bristol, and in 1768 dean of St. Paul's. In 1749-'52 he published the first critical edition of Milton's "Poetical Works" with variorum notes (3 vols. 4to.). His "Dissertations on the Prophecies" (8 vols. 8vo., 1754-'8) became very popular, and were translated into German and Danish. A collected edition of his writings appeared in 1782 (8 vols. 4to., London).

NEY, MICHEL, duke of Elchingen and prince of the Moskva, a French marshal, born in Sarrelouis, Jan. 10, 1769, executed in Paris, Dec. 7, 1815. The son of a cooper, he was first an errand boy or under clerk in a notary's office; but enlisting in the army at the age of 18, he was soon promoted, and when the revolution of 1789 broke out was sub-lieutenant in a regiment of hussars. In 1794 he was a captain in

the army of the Sambre and Meuse under Jourdan, where he attracted the attention of Kléber, who caused him to be promoted, and sent him on several expeditions which proved successful and procured him the surname of *l'infatigable*. During the campaign of 1796 he distinguished himself in the battles of Altenkirchen, Würzburg, and Forchheim. In 1797, under Hoche, who had been placed at the head of the army of the Rhine, he was made a brigadier-general for his gallantry in an engagement on the Rednitz, and by a brilliant charge contributed to the victory of Neuwied (April 18). A few days later, during a skirmish at Diernsdorf, his impetuosity led to his being taken prisoner, but he was forthwith exchanged. In 1799 he was placed in command of a brigade in the army of the Rhine under Bernadotte, and at the head of 150 men surprised Mentz, for which he was rewarded with the rank of general of division. He now served under Masséna, whom he accompanied in the valley of the Danube; and when that general concentrated his forces on the banks of the Limat to withstand the attack of the combined Austrians and Russians under Suwaroff, Ney, at the head of a separate corps, kept the archduke Charles at bay, and thus indirectly contributed to the victory of Zürich, by which France was preserved from invasion. He approved of the *coup d'état* of the 18th Brumaire. Under Moreau he participated in most of the engagements that marked the spring campaign of 1800 in Germany, and during the winter was engaged in the celebrated victory of Hohenlinden (Dec. 3), which brought Austria to terms. During the peace which followed he married, by Bonaparte's advice, Mlle. Auguié, a schoolmate and bosom friend of Hortense Beauharnais. He was appointed inspector-general of cavalry and minister plenipotentiary to Switzerland, and in 1803 was placed in command of the 6th corps at the camp of Boulogne, where the French army was preparing for the invasion of England. He was still there when, on Napoleon's accession to the empire, he received, as "a reward for his long series of heroic deeds," the title of marshal. On the renewal of hostilities in 1805, he led one of the corps of the great army which, under command of the emperor himself, crossed the Rhine to subdue Austria. He displayed his wonted energy, particularly at Elchingen, where he not only evinced great generalship, but "fought as bravely as any private," and received the title of duke of Elchingen. He forced Mack into Ulm by his skillful manœuvres, penetrated into the Tyrol, routed the archduke John, took possession of that province, and seconded the operations which resulted in the decisive victory of Austerlitz. The Prussian campaign (1806-'7) afforded new opportunities for the display of his unrivalled gallantry; he was instrumental in the victory of Jena, forced Magdeburg to capitulate, was the first to face the Russians when they entered the city, rescued his colleague Bernadotte

at Mohrungen, defeated the Prussians under Lestocq, held his ground in the dreadful but undecided contest at Eylau, and finally determined the triumph of the French army at Friedland. Here he was in command of the right wing, which bore the brunt of the battle and stormed the town. Napoleon, as he watched him passing unterrified through a shower of balls, exclaimed: "That man is a lion;" and henceforth the army styled him *le brave des braves*. Being sent to the Peninsula in 1808, he took possession of the Asturias and Galicia, attacked Portugal with some success, and, when the French army under Masséna was compelled to fall back, protected its retreat with great skill. He was nevertheless recalled to France, Napoleon's confidence in his sincerity being somewhat shaken; and for nearly two years he lived in a kind of disgrace. But his services were wanted for the Russian war in 1812, and he was reinstated in his command. He defeated the Russians at Krasnoi, shared in the capture of Smolensk, and bore himself so heroically at the battle of Borodino that to the title of duke of Elchingen Napoleon added that of prince of the Moskva. He remained exposed during the whole day to the fire of the enemy, and while he occasionally ordered his soldiers to stoop or lie down in order to avoid the discharges of artillery, he himself stood immovably erect. But it was during the disastrous retreat that he proved, as Napoleon said, that "his soul was tempered with steel." For several days he had been separated from the army and was thought to be lost, when, at the head of his dreadfully reduced corps, he reappeared, having defeated all the Russian troops that obstructed his way. When Napoleon left the army, and Murat himself fled as if in despair, Ney showed an iron will supported by iron strength; he saved all that could be saved in this terrible wreck. On his arrival at Hanau, regardless of past fatigues and sufferings, he worked day and night to organize the new army which was to make another stand against the combined forces of Europe. He figured conspicuously at Lützen, Bautzen, Dresden, and Leipzig; and when the French army evacuated Germany, he commanded the rear guard. France was now invaded (1814); he fought to the last against the advancing enemy, in the battles of Brienne, Montmirail, Craonne, and Châlons-sur-Marne. But though he fulfilled his duty as a soldier in this last crisis, he found himself quite bewildered when launched on the sea of politics. He was among the foremost to insist upon Napoleon's abdication, and is even charged with having acted in the rudest manner toward the fallen emperor. On his deposition being declared, April 11, 1815, Ney flew to Louis XVIII., who welcomed him in the most flattering terms and overwhelmed him with distinctions; he made him a peer of France, grand officer of the order of St. Louis, chief of nearly the whole French cavalry, and commander of the 6th military district, the

head-quarters of which was at Besançon. On hearing of Napoleon's landing at Cannes, he repaired to his post, after promising under oath to Louis XVIII. that he would bring him the fugitive from Elba a "prisoner in an iron cage." He no doubt intended to keep his word; but when he heard of the enthusiastic reception of Napoleon at Lyons, when he saw his old companions flocking around the emperor, when his own troops called anxiously upon him to lead them to their chief, he could not resist the contagion, seconded perhaps by the impulse of his own feelings; he proclaimed Napoleon the only legitimate sovereign of France, and hastened to join him at Auxerre. He returned with him to Paris, which they entered March 20, 1815. In less than 8 months afterward they were marching to Belgium, Ney leading the right wing of the French army. He fought (June 18) all day long at Quatre-Bras; and in the battle of Waterloo in his terrible attack upon La Haie-Sainte, he displayed an energy, a boldness, and a disregard of his own life, worthy of his most brilliant days. He had no fewer than 5 horses killed under him. But in the sitting of the chamber of peers, June 22, he openly declared that every thing was lost, that the enemy could come in whenever they pleased, and that the only means of saving the country was to open negotiations. This, at such a time, was little short of treason. He was not employed by the provisional government; and the king, on his return, issued against him and several others, on July 14, a decree of proscription. Ney had vainly hoped that his life would be protected by the terms of the capitulation of Paris. He at first escaped to Anvergne, but was discovered and arrested in October, brought to Paris, and arraigned before a court martial, consisting of Marshals Moncey, Angereau, Masséna, and Jourdan. These old brothers in arms eagerly availed themselves of a legal technicality to declare their incompetency to judge him; and the case was consequently transferred to the court of peers. Here the majority consisted of his political or personal enemies, so that, notwithstanding the able defence of his counsel, Dupin and Berryer, he was sentenced to death on Dec. 6. He now resumed all his self-possession and firmness. On the following morning, after taking a short and touching farewell of his wife and sons, he was marched to the end of the Luxembourg garden; there, placing himself in front of the troops who were to shoot him, throwing his hat away, and pressing his right hand to his heart, he cried: "*Vive la France!* Fellow soldiers, fire here!" He was killed instantly. This execution, which was warranted by no political necessity, deeply wounded the popular feeling; and Armand Carrel echoed the voice of the nation, when, some years later, in the chamber of peers, where he himself had been arraigned, he declared that the death of Ney was an

abominable assassination. Ney was buried on the 8th in the cemetery of Père Lachaise. His *Mémoires* (2 vols. 8vo., 1838) were published by his widow and sons, and Dumoulin has given a full account of his trial (*Histoire complète du procès du Maréchal Ney*, 2 vols. 8vo., 1815). Attempts were subsequently made at various times to have the sentence reversed by the chamber of peers; but they failed. It was however cancelled by public opinion, and a bronze statue was erected to him in 1854 on the spot where he was executed. Ney left 4 sons, Joseph Napoléon, Michel, Eugène, and Edgar.—JOSEPH NAPOLÉON, prince of the Moskva, born May 8, 1808, died July 26, 1857. He married in 1838 the daughter of Jacques Laffitte, the banker, was appointed aide-de-camp to the duke of Orleans after the revolution of 1830, and was promoted to a peerage in 1831, but did not take his seat in the chamber until 1841, after solemnly protesting against his father's condemnation. In 1848 he sided with the democratic party, and was a member of the club which sent a "democratic foreign legion" of 1,800 men to aid in the revolution of Baden. He was elected a member of the legislative assembly by the departments of Moselle and Eure-et-Loir in 1849, and attached himself to the party of the prince president. He was one of the first senators created under the empire. After having been colonel of lancers and dragoons, he was appointed brigadier-general in 1853; but he was better known as a patron of arts, literature, and the turf, than as a soldier, having for some time before his death withdrawn from active service. He composed an opera called *Régine*, contributed to the *Revue des deux mondes*, and was one of the original members of the French jockey club. His only daughter is the wife of Count Persigny, French minister at London.—NAPOLÉON HENRI EDGAR, born in Paris, March 20, 1812, was one of the officers of the prince president; and it was to him that the latter addressed the famous letter (April 18, 1849) on the French expedition to Rome, which caused such a sensation in the legislative assembly. In 1852 he became adjutant and first huntsman of the emperor, in 1855 commandant of the legion of honor, and in 1856 brigadier-general; and at the end of 1857, after the death of his brother, the emperor conferred on him the title of prince of the Moskva.

NGAMI, a lake in S. Africa, about 70 m. in circumference, with its centre in lat. 20° 40' S. and long. 22° 40' E. It is of an elongated form, contracting about the middle; its breadth nowhere exceeds 9 m. The N. shore is sandy, low, and barren for about a mile, beyond which the country is well wooded. The opposite shore is elevated, fringed with belts of reeds and bushes, and only accessible in a few places where cattle have broken through. The lake rises and falls 2 or 3 feet, but it is not known whether this is caused by the wind acting on the surface of the water, or by the

moon's attraction. The lake is fed by the Tioghe river at its N. W. extremity. This stream, whose source is unknown, is about 40 yards broad, but very deep when at its highest stage. It overflows in June, July, and August, and sometimes later. The Zouga, a broad and sluggish river, issues from the E. extremity of the lake; its width at the outlet is 200 yards. It is stated by the natives that it communicates with the Tioghe by a branch which at certain seasons of the year forces the waters of the Zouga back into the lake. The latter stream, after an E. course of about 800 m., appears to be lost in a vast marsh; but it is thought by some that, like several other African rivers, it continues its course subterraneously, and ultimately finds its way to the sea. Exaggerated reports concerning Lake Ngami reached travellers in S. Africa about the beginning of the 19th century. It was first visited by Livingstone in 1849, and since that time several other Europeans have seen it, among whom was the Swedish traveller Charles John Andersson.—See Andersson's "Lake Ngami" (London and New York, 1856).

NIAGARA, a N. W. co. of N. Y., bounded N. by Lake Ontario and W. by the Niagara river; area, 558 sq. m.; pop. in 1855, 48,282. It is watered by Tonawanda creek on the S. border, and Four, Six, Twelve, and Eighteen Mile creeks (named from their distances from the mouth of Niagara river), Fish, Golden Hill, Cayuga, and other creeks, several of which afford excellent water power. The surface is generally level or slightly undulating, and the soil with some exceptions fertile. The productions in 1855 were 595,297 bushels of wheat, 358,398 of oats, 79,593 of barley, 509,505 of Indian corn, 275,448 of potatoes, 255,997 of apples, 41,117 tons of hay, 1,088,307 lbs. of butter, and 71,443 of cheese. There were 81 brass and copper foundries, 4 furnaces, 24 coach and wagon manufactories, 17 flour mills, 41 saw mills, 4 tanneries, 3 daily and 5 weekly newspapers, 92 churches, and 17,725 pupils attending schools. The county is traversed by the Erie canal, and the Rochester, Lockport, and Niagara Falls, the Buffalo and Lockport branch, the Buffalo and Niagara Falls, and the Canandaigua and Niagara Falls branch railroads. Capital, Lockport.

NIAGARA, a river 88 m. long, forming part of the boundary between the United States and Canada West, and connecting Lake Erie with Lake Ontario. It is the outlet of the former lake, and the channel by which all the waters of the 4 great upper lakes flow toward the gulf of St. Lawrence. In their short passage from Lake Erie to Lake Ontario there is a total descent of 384 feet, leaving the lower lake still 281 feet above the sea. The interruption to the navigation occasioned by the rapid descent of the Niagara river is overcome on the Canadian side by the Welland canal (see CANAL, vol. iv. p. 844); and on the American side the communication between tide water

and the upper lakes was first effected by the Erie canal. From the N. E. extremity of Lake Erie the Niagara river flows in a northerly direction with a swift current for the first 2 m., and then more gently with a widening current, which divides as a portion passes on each side of Grand island. As these unite below the island, the stream spreads out to 2 or 3 m. in width, and appears like a quiet lake studded with small low islands. About 16 m. from Lake Erie the current grows narrow and begins to descend with great velocity. This is the commencement of the rapids, which continue for about a mile, the waters rolling in great swells as they rush swiftly down among the rocks, accomplishing in this distance a fall of 52 feet. The rapids terminate below in a great cataract, the precipitous descent of which is 164 feet on the American side and 150 on the Canadian. At this point the river, making a curve from W. to N., spreads out to an extreme width of about 4,750 feet. Goat island, which extends down to the brink of the cataract, occupies about one fourth of this space, leaving the river on the American side about 1,100 feet wide, and on the Canadian side about double this width. The line along the verge of the Canadian fall is much longer than the breadth of this portion of the river, by reason of its horse-shoe form, the curve extending up the central part of the current. The waters sweeping down the rapids are carried with great velocity over the edge of the precipice, and form a grand curve as they fall clear of the rocky wall into the deep boiling pool at the base. The space between this sheet of water and the wall widens near the bottom, the strata being there of a loose shaly character, and consequently hollowed out by the continual action of the spray. A cave is thus formed behind the fall, into which on the Canadian side persons can enter and pass by a rough and slippery path toward Goat island. Among the great cataracts of the globe that of Niagara stands preëminent for the enormous volume of water that is carried over so high a precipice. In the mountainous regions of the earth numerous falls are known that descend from far greater heights; but the sublimity of Niagara is in the vast power displayed by a mighty current descending impetuously, first by rushing down the long inclined plane of the rapids, and finally plunging in one unbroken vertical sheet into the deep abyss below. The only outlet of the lakes, whose area exceeds that of all the other lakes upon the globe, its current experiences comparatively little change.—In the vicinity of the falls the scenery presents no features in keeping with the sublimity of the great cataract itself. The river flows from Lake Erie to the head of the rapids through a level and monotonous region; and below the falls the country continues of the same character, interrupted only by the precipitous chasm or gorge excavated by the river to the depth of 150 feet or more below the general

surface. The sound of the fall varies greatly with the condition of the atmosphere and the wind. Much of the time it is heard but a little distance off, and again it rolls over the land to the shores of Lake Ontario, and across its waters even to Toronto, 46 m. distant. At the edge of the abyss it is heard in full force, a deep monotonous rumbling like that which a thousand great mills might create with their machinery. In the deep chasm below the fall the current, contracted in width to less than 1,000 feet, is tossed tumultuously about, and forms great whirlpools and eddies as it is borne along its rapidly descending bed. Dangerous as it appears, the river is here crossed by small boats; and a little steamboat, called the *Maid of the Mist*, navigates this portion of the river, taking passengers up nearly to the foot of the falls. On each side of the gorge the walls rise almost perpendicularly from the talus of fragments piled up along their base, and access to and from the summit is had only by means of stairways constructed at several points. For 7 m. below the falls the narrow gorge continues, varying in width from 200 to 400 yards. The river then emerges at Lewiston into a lower district, having descended 104 feet from the foot of the cataract. Several objects of interest are met with in this portion of its course. Within 2 m. of the falls is the wire suspension bridge, thrown across the gorge at the height of 258 feet above the water, and supported by towers upon each bank, the centres of which are 800 feet apart. The current itself is here about 350 feet wide. The bridge was constructed in 1855 by Mr. Roebling for the passage of railway trains, and 28 feet below the railway it also sustains a carriage and foot track. From this bridge a fine though distant view is had of the falls. Three miles below the falls the river, bending toward the Canadian side and contracted to a width of about 220 feet, rushes violently into a deep depression in the steep cliff on that side, from which it emerges, turning back almost at a right angle into the American side, still very narrow, but flowing with a gentle current. The remarkable depression in the western bank presents the appearance of having been hollowed out by a great eddy or whirl of the waters, and it is known as "the whirlpool." But the river now flows sluggishly through it, and its slow course in the very narrow chasm below is no doubt occasioned by the great depth to which its bed is excavated in the soft strata at this point. The depression proves to be a portion of the bed of an ancient channel, now filled with diluvium, but traceable over the surface, and supposed to connect with another gorge that cuts the high terrace at St. David's, 4 m. W. of Queenston. The surface of the country, which at the foot of Lake Erie is low, scarcely rising above the level of its waters, gradually becomes more elevated toward the N., till near Lewiston it is 88 feet higher than Lake Erie. The course of the Niagara river is thus in the direction of

the ascent of this inclined plane, and must originally have been induced by a depression in the surface. Beyond this there occurs a sudden descent toward Lake Ontario of 250 feet, down to the plateau upon which stands on the American side of the river the village of Lewiston, and on the Canadian that of Queenston. The high land forms a bold terrace looking out upon Lake Ontario, from which it is 7 m. distant, and from its foot the surface descends so gently to the lake that the fall, amounting to 120 feet, is hardly perceptible. The fall made by the river in this lowest portion of its course is only 4 feet; and as this does not impede navigation, Lewiston and Queenston are both ports connecting with Lake Ontario.—The gorge through which the Niagara river flows below the falls, amounting at the terrace to about 366 feet in depth, bears striking evidence to the casual observer of having been excavated by the river itself, and this impression is fully confirmed on a closer examination of the geological features about the falls and the gorge below. Moreover, in the short period, hardly reaching back into the last century, during which observations other than those of passing travellers have been made and preserved, changes have taken place by the falling down of masses of rock, the effect of which has been to cause a slight recession of the cataract, and extend the gorge to the same amount upward toward Lake Erie. Thus in 1818 great fragments descended at the American fall, and again in 1828 at the Horse Shoe fall, in each instance the country being shaken by the concussion as if from an earthquake. The impression of the older residents has been that the line of the falls has receded 50 yards in 40 years; but this is based upon no exact measurements, and until the careful trigonometrical survey made in 1842 under direction of Prof. James Hall, for the state geological survey, no marks nor monuments had been fixed, by which the rate of recession could be ascertained. The results of this survey, with the map of the falls, are presented in the state geological report of Prof. Hall. In the same report is a fac-simile of a view of the falls by Father Hennepin, made in the year 1678, and first published in his descriptive work of the country at Utrecht in 1697, and in London the succeeding year. This sketch and the accompanying description are interesting, as they both present a striking feature in the falls which has now entirely disappeared. This is a third fall from the Canadian side toward the east, across the line of the main fall, and caused by a great rock that turned the divided current in this direction. In 1750 the falls were visited by Kalm, a Swedish naturalist, whose description and view were published in the "*Gentleman's Magazine*" in 1751. He alludes to the rock having fallen down a few years previous, and indicates the spot in his sketch. From such evidences it is certain that changes are and have been taking place, the effect of which in long

periods of time would have excavated the great gorge, and in time to come would carry it further up the stream toward Lake Erie. But the rate at which these changes take place cannot be determined with accuracy. The popular estimate of 50 yards recession in 40 years is regarded by those who have given most attention to this subject as greatly exaggerated. Lyell considers that a foot a year is a much more probable conjecture. From the variable nature of the strata over which the river flows, the circumstances that affect the rapidity of the cutting action differ all along its course. At the present site of the falls sheets of a hard limestone rock, of the formation known as the Niagara limestone, cover the surface of the country, and form the edge of the cataract to the depth of between 80 and 90 feet. Under this, extending to the foot of the fall, are the shaly layers of the same formation. All these strata slope downward against the current of the river at the rate of about 25 feet in a mile; and in the rapids above the fall the uppermost layers of the Niagara limestone succeed, one stratum above another, till about 50 feet more is added to the thickness of the formation, when all disappear beneath the outcropping edges of the next series above, which is that of the shales and marls of the Onondaga salt group. In the other direction, toward Lake Ontario, these strata gradually rise to higher levels, till along the great terrace the capping is of the lower 20 feet of the Niagara limestone, below which the shaly strata form the next 80 feet of the steep slope; and next appears a succession of calcareous layers, shales, and sandstones, belonging successively to the Clinton and Medina formations. Through these piles of strata the river has worked its way back, receding probably most rapidly where, as in its present position, the lower portion of the cutting was composed of soft beds, which being hollowed out let down the harder strata above; and less rapidly where the strata near the base were hard sandstones, such as occur in some of the lower groups. The effect of continued recession must be to gradually diminish the height of the falls, both by the rising of the bed of the river at their base and by the slope of the massive limestone to a lower level. The thin-bedded limestones above being swept off, the succeeding shales and marls of the Onondaga salt group must immediately follow, and the falls may then become almost stationary, when their base is at the base of the massive sandstone and their upper line is as now over its upper edge. This, as shown by Prof. Hall, is likely to be the case after a further recession of about 3 m., and the height of the fall must then be reduced to about 80 feet.—Beside the facts referred to above, bearing upon the erosive action of the current, there is conclusive geological evidence that the river has flowed for a distance of full 4 m. below the cataract at a level more than 40 feet above its present position at the head of the falls and this within the present geological

period. On both sides of the river, and especially on Goat island, are beds of sand, gravel, and clay, evidently deposited by running water, containing great numbers of fresh water shells of the same genera and species as those now living in the river and deposited along its banks, such as the *unio*, *cyclus*, *limnea*, *planorbis*, *valvata*, and *melania*. These strata reach to the height of 40 feet above the top of the fall, and are met with in occasional patches at the same level near the edges of the precipice for 4 m. below. They show that the waters must have spread over a wide area and been kept back by some high barrier between the whirlpool and Lewiston. This was probably little if any short of the high terrace itself. Among the fossil remains in these deposits, a mammoth's tooth was discovered 11 feet below the surface. The boulder or drift formation underlies the fluvial strata, thus referring their formation to the latest geological period.—The most complete accounts of Niagara falls are contained in the report of Prof. Hall already referred to, and in vol. i. of "Travels in North America," by Sir Charles Lyell.

NIASSA. See NYASSA.

NIBELUNGEN-LIED, or NIBELUNGEN-NOCH, an old German epic poem, embodying several cycles of heroic traditions. The author of the latest recension of the poem is entirely unknown, and its date is assigned by Bunsen to about A. D. 1200. The legends which it contains form a large part of the German *Heldensagen*, and are found with various modifications in other Teutonic and Scandinavian poems. In Worms, it records, reigned King Günther over the Burgundians, having two brothers, Giselher and Gernot, and a sister, Chriemhild, the world's wonder, of whose rare grace and beauty a description is given. She forswears marriage in consequence of a dream; but the gallant Siegfried, the Achilles of both Scandinavian and Teutonic legends, who had slain a dragon, vanquished the ancient fabulous royal race of the Nibelungen, and taken away their immense treasures of gold and gems, comes to Worms to woo her for his bride. He is welcomed, triumphs over all the knights of Burgundy who venture to meet him, wins her heart by his valor, though she sees him only from a grated window, but had begun to despair of success when Günther hears of the beautiful and redoubtable Bruneild, queen of Iseiland, and resolves to stake his fortune as her suitor. The condition was that he should engage in 3 combats with her, and if vanquished be put to death. Siegfried accompanies and aids him, being promised the hand of Chriemhild if he should be successful. The united heroes reach their destination after a voyage of 12 days. Bruneild appears in the lists with a shield of beaten gold, so heavy that 4 of her chamberlains can scarcely bear it. Günther is in despair, when the touch and voice of an invisible person by his side gives him courage for the fight. The same person seizes his arm, hurls

the spear, and flings the stone, till the martial maid confesses herself vanquished, and bids her vassals do homage to Günther as their lord. Siegfried, the real winner of the contest, who had been made invisible by his magic cap, receives for his reward the hand of Chriemhild, and the two marriages are celebrated amid the utmost pomp and rejoicing. Dissension ensues between the queen and her sister-in-law; Siegfried contrives to obtain the girdle of the former, and to present it to the latter, who afterward tells the whole tale of her husband's valor, and charges her rival with love for him and infidelity. The latter vows revenge, and secures the aid of the fierce and covetous Hagen, who sought the gold and gems of the Nibelungen, and who skilfully draws from Chriemhild the secret of the spot where alone Siegfried was mortal, and soon after treacherously and fatally plunges a lance between his shoulders in a royal chase. After this Chriemhild lived in melancholy at Worms for 18 years, Hagen having sunk all her Nibelungen treasure somewhere in the Rhine. Then Etzel (Attila), king of the Huns, seeks her in marriage, and she consents, in order that she may avenge the death of Siegfried. After 7 years of repose in Hungary she persuades Etzel to invite Günther and his heroes to visit him. They accept, and go with a retinue of 10,000 men, though Hagen forebodes disaster, and though evil omens abound. At the castle of Rüdiger, ambassador of the king, they are hospitably entertained, and Gieselher is betrothed to the host's daughter, who according to the custom greets the guests with a kiss, but falls back shuddering from Hagen. Provided with gifts, they advance into mighty Etzel's land, who receives them with honor; but the queen greets Hagen coldly, who is consequently too suspicious and watchful to be assassinated secretly. A tumult at length ensues, which results in a dreadful battle in which many of the heroes on both sides are slain, and Etzel and Chriemhild are barely rescued from the hall in which the Burgundians were raving with Berserkir rage. The hall is then vainly assailed by 20,000 Huns. Günther seeks a reconciliation, but rejects the proffered terms requiring the surrender of Hagen, and the queen orders the edifice to be set on fire. Six hundred only survive the conflagration by penetrating deep into the walls. The contest is renewed by Rüdiger, and numerous heroes are so nearly matched that they slay each other, until at last of all the Burgundians only Günther and Hagen remain, who are delivered in bonds to Chriemhild. She demands of the latter where the Nibelungen treasure is concealed, but he refuses to betray it so long as one of his lords lives. The head of Günther is struck off, but Hagen still declares that he alone of men knows the secret, and that he will not reveal it. She then grasps the sword of Siegfried, and beheads him by a blow, but the Hunnish warrior Hildebrand disdains to see a hero fall beneath a woman's hand, and slays the queen;

and Etzel and Dietrich survive alone to lament the dead.—Notwithstanding the horrors and improbabilities of the poem, the action of which extends over a period of 80 years, it abounds in passages of remarkable beauty and power. The origin of the traditions embodied in it is usually attributed to the Scandinavians. They are contained in the Edda, the Brynhilda, Gudrun, and Sigurd of which are only the personages of the Nibelungen-Lied in more gigantic outlines. But they probably existed from an early period among the ancient Germans, and both the sagas and the lays may have been but different versions of the same tradition. In both the hero kills a dragon and renders himself invulnerable; in both he becomes master of a priceless treasure. Brynhilda appears in both: in the Nibelungen as a mortal woman endowed with supernatural strength; in the Edda as a Valkyre watching over the fate of battles, plunged into a magic sleep by Odin, released from the spell by Sigurd, by whom she is loved and forgotten. The spirit of the Edda is fiercer and more savage than that of the Nibelungen, and wholly pagan, while the latter is marked by the milder influence of Christian chivalry. A striking discrepancy exists between the Attila of history and Latin tradition and the Attila of the northern lays. In the latter, though "the scourge of God" does not become a Christian, he is endowed with every Christian virtue, and even shows an inclination to be converted. The *Klage*, or lament, which forms an appendix to the Nibelungen, is a species of epilogue in which the disasters of the story are reviewed. In its most remarkable passage Chriemhild receives divine pardon, because the motive which had led her to the guilt of blood had been reverence for truth. This is the key to the character of the whole poem, the pervading sentiment of which is truthfulness and sincerity. In the Volsunga Saga the whole interest is concentrated in the unhappy and terrible passion of Brynhilda; the genius of the North finds in her Amazonian heroism its deepest and fairest expression; but the charm of the Nibelungen is its simplicity and truth.—The researches concerning the origin of the poem make it probable that at different times and places 5 groups of traditional legends came into existence, relating respectively to Siegfried and Brunehild, Günther and his sisters, Hagen, Dietrich, and Etzel. These were related to and modified by each other, until they made one cycle of popular songs. The form of the principal of these songs was much changed in the latter part of the 12th century in consequence of the prevalent culture of poetry during the Swabian period, and wandering minstrels gave to them more and more of a rhapsodical and epical character. Early in the 18th century in Austria a noble poet, acquainted with the best courtly productions of the time, combined the multifarious songs and rhapsodies into a regular epical whole, exhibiting a masterly genius

in his conception of the plan and in the skill with which he reduced innumerable characters and events to an essential though not formal unity. It seems to have been less popular in the middle ages than other romances, being disliked by the clergy on account of its heathenish character, and by the courtly poets on account of its rudeness. It is substantially the work of an age anterior to Christianity, civilization, and the more refined customs of chivalry. The remodelling of the work has been twice attempted within a few years, but the form which it had previously assumed was not superseded. Holtzmann describes 27 manuscripts of the poem, 10 of which are complete. They are divided into two groups, the elder bearing the title of *Nibelungen-Lied* and the more modern that of *Nibelungen-Not*, both however of essentially the same contents. The oldest manuscript extant belongs to the 18th century, and more than 20 are older than the 16th. It was not, like Wolfram's *Parzival*, one of the early printed books, was known in the 16th century only to a few historians, and was almost forgotten in the 17th century. Bodmer was the first to revive an interest in it by publishing fragments under the title of *Christenheides Rache* (1751). The first complete edition was produced by C. H. Müller (1782). The romantic school of Germany raised it to the highest honor. Von der Hagen was the first to thoroughly treat it, and published it with a glossary (1807). Lachmann distinguished 8 versions in the different manuscripts, the oldest of which he separated into 20 distinct epical songs, and published a critical edition (1836). The principal other versions have since been printed. The contents of the poem were meantime investigated by Grimm, Lachmann, Götting, Mone, Spaun, and others. The best translations into modern German are by Simrock (1827) and Pfitzer (1842-'8). There are English translations by Birch (1848), and Lettsam (1850).

NIBOYET, EUGÉNIE, a French authoress and social reformer, born about 1804. She commenced her literary career by translating the works of Mrs. Barbauld, Miss Edgeworth, and Mrs. L. M. Child. She afterward wrote educational books, such as *Dieu manifesté par les œuvres de la création* (4 vols. 18mo., 1842), which received a prize from the society of Christian morals, and several novels, among which were *Les deux frères* (1839), and *Cathérine II.* (1847). In the meanwhile she became a prominent advocate of prison reform, contributed to the establishment of a philanthropic bank, and in 1844 founded a socialist newspaper, *La paix des deux mondes*, in which questions relating to industry, trade, science, and literature were freely discussed. On the breaking out of the revolution of 1848, she came forward to advocate the rights of women, opened a woman's club, and issued a periodical entitled *La voix des femmes*. The club was closed by the police, and her journal changed its name to that of *L'avenir*. It was soon dis-

continued, and Mme. Niboyet retired to private life. Since then her only appearance before the public has been as the writer of a preface to a novel entitled *Les amours d'un poète*, by her son, Paulin Niboyet.

NICANDER, a Greek poet and grammarian, who probably flourished in the middle of the 2d century B. C. He was a native of Claros in Ionia, and succeeded his father as priest in the temple of Apollo. He was a voluminous author, but none of his works have come down to us except two poetical treatises, one on venomous animals, the other on poisons and their antidotes. The earliest edition is that of Venice (1499); the best that of J. G. Schneider (Halle, 1792; Leipsic, 1816).

NICARAGUA, a republic of Central America, formerly a province of the royal audiencia of Guatemala, lying between lat. 10° 45' and 15° N., long. 88° 20' and 87° 30' W.; area (including the Mosquito shore), about 50,000 sq. m. It is bounded E. by the Caribbean sea, from Cape Gracias á Dios at the mouth of the Rio Wanks or Segovia, southward to the port of San Juan, at the mouth of the river of the same name; N. by the republic of Honduras, from which it is separated, for most of its course, by the Rio Wanks; W. by the Pacific ocean. The dividing line between the republic and Costa Rica on the S. was for a long time a subject of dispute, but was settled by convention between the two states, April 15, 1858, as follows: starting from Punta de Castilla, or Punta Arenas, on the S. shore of the harbor of San Juan, and thence following the right bank of the river San Juan to within 8 m. of the old fort known as Castillo Viejo; at this point the line falls back 2 m. from the river, preserving that distance from the stream to the point whence it issues from Lake Nicaragua, following along the southern shore of that lake, at an equal distance inland, until it strikes the river Sapoa, flowing into the lake, and thence due W. to the bay of Salinas, on the Pacific. A claim to a considerable part of the territory thus defined, embracing the entire Atlantic coast, and extending indefinitely inland, was set up some years ago by Great Britain, on behalf of the "king of the Mosquitos;" but by a convention bearing date Aug. 28, 1860, Great Britain finally gave up her pretensions, and the "Mosquito Shore" has accordingly devolved under the sovereignty of Nicaragua.—Politically, Nicaragua is divided into 5 departments, as follows:

Departments.	Population.	Capitals.
Meridional, or Rivas	20,000	Rivas.
Oriental, or Granada	25,000	Granada.
Occidental, or Leon	20,000	Leon.
Septentrional, or Segovia	12,000	Segovia.
Matagalpa	40,000	Matagalpa.
Total	237,000	

The population here given is the result arrived at, in round numbers, by a census attempted in 1846. It was only partially successful, as a

large part of the people supposed that it was preliminary to some military conscription or tax levy. Making due allowances for deficiencies in the census of that year, and for increase since, we may estimate the actual population of the state, in round numbers, at 800,000, divided approximately as follows: whites, 80,000; negroes, 18,000; Indians, 86,000; mixed, 156,000; total, 800,000. The capital is Managua. In the census above referred to, the following were given as the approximate populations of the principal towns of the state: Acoyapa, 500; Chichigalpa, 2,800; Chinandega, 11,000; Chinandega Viejo, 3,000; Granada, 10,000; Leon, including Subtiaba, 80,000; Managua, 12,000; Masaya, 15,000; Matagalpa, 2,000; Nagarote, 1,800; Nicaragua, 8,000; Posultega, 900; Pueblo Nuevo, 2,900; Realejo, 1,000; Segovia, 8,000; Somotillo, 2,000; Sonci, 2,500; Telica, 1,000; Villa Nueva, 1,000. The females greatly exceed the males in number. In the department Occidental, according to the census, the proportion was as three to two. It is difficult to account for this disparity, except by supposing it to have been the result of the civil wars which, for some years previously, had afflicted that portion of the state. It should nevertheless be observed, that throughout all parts of Central America there is a considerable preponderance of females over males. Most of the people of Nicaragua live in towns or villages, many of them going 2, 4, and 6 miles daily to labor in their fields, starting before day and returning at night. Their plantations, *haciendas*, *hattos*, *huertas*, *ranchos*, and *chacras*, are scattered pretty equally over the country, and are often reached by paths so obscure as almost wholly to escape the notice of travellers, who, passing through what appears to be a continuous forest from one town to another, are liable to fall into the error of supposing the country to be almost wholly without inhabitants.—Placed on a narrow isthmus between the two oceans, its ports opening to Europe on one hand and to Asia on the other, midway between the northern and southern continents of America, Nicaragua seems to realize the ancient idea of the geographical centre of the world. These geographical advantages are rendered especially interesting and important from the interior features of the country, which are supposed to afford facilities for water communication between the seas, superior to those of any other part of the continent. These features are principally determined by two ranges of mountains which traverse the state in a direction nearly due N. W. and S. E. One of these, which may be called the volcanic or Pacific coast range, starts in the high lands of Quesaltenango in Guatemala, and, extending through San Salvador and Nicaragua, terminates in the great mountain group or nucleus of Costa Rica. It follows the general direction of the coast, sometimes rising in lofty volcanic cones, but generally sustaining the character of a high ridge, subsiding in

places into low hills and plains of slight elevation. It preserves a nearly uniform distance from the sea of from 10 to 20 m., and consequently there are no considerable streams falling from it into the Pacific. It seems to have been the principal line of volcanic action, and in Nicaragua is marked by the volcanoes of Cosseguina, El Viejo, Santa Clara, Telica, Arusco, Las Pilas, Orotá, Momotombo, Masaya, Mombacho, Ometepe, and Madeira, and by numerous extinct craters, surrounded by vast beds of lava and deposits of scoria. The second, or principal mountain range, the great backbone of the continent and the true Cordilleras, enters the state from Honduras, in the department of Nueva Segovia, and extends due S. E. until it strikes the San Juan river at a point about 50 m. above its mouth. It sends out numerous spurs or dependent ranges toward the Atlantic, between which flow down the many considerable streams that intersect what is called the Mosquito shore. Between these two ranges of mountains is formed a great interior basin, not far from 800 m. long by 100 m. wide, in the centre of which are the broad and beautiful lakes of Nicaragua and Managua, the characteristic and most important physical features of the country. These lakes receive the waters which flow down from the mountains on either hand, and discharge them through a single outlet, the river San Juan flowing through a narrow break in the Cordilleras into the Atlantic. Some of the streams falling into these lakes from the north are of considerable size, and furnish a supply of water, in excess of evaporation, which could not be sensibly affected by drains for artificial purposes. Lake Nicaragua, the ancient Cocibolca, is the largest body of water in Central America. On its S. shore, near the head of the lake, stands the ancient city of Granada, lately the rival of Leon, and once the most important commercial town in the republic. Flowing into the lake, at its extreme S. extremity, nearly at the same point where the Rio San Juan (the ancient El Desaguadero) commences its course, is the considerable Rio Frio, which has its origin near the base of the great volcano of Cartago, in Costa Rica. It flows through an unexplored region, inhabited by an unconquered and savage tribe of Indians, called Guatusos, of whose ferocity the most extraordinary stories are related. (See GUATUSOS.) The N. shore of the lake, called Chontales, is undulating, abounding in broad savannas, well adapted for grazing and supporting large herds of cattle. The water of the lake in most places shoals very gradually, and it is only at a few points that vessels of considerable size can approach the shore. Still, its general depth, for all purposes of navigation, is ample, except near its outlet, where for some miles it does not exceed 5 or 10 feet. There are points, however, where the depth of water is not less than 40 fathoms. As already observed, the sole outlet of the great Nicaragua basin, and of the

lakes which occupy it, is the river San Juan, debouching into the Caribbean sea at the port of San Juan, or Greytown. This river is a magnificent stream, but its capacities have been greatly exaggerated. It flows from the S. E. extremity of Lake Nicaragua, nearly due E. to the ocean. With its windings, it is 119 m. long. The body of water which passes through it varies greatly at different seasons of the year; it is of course greatest during what is called the "rainy season," that is to say, from May to October. Several considerable streams enter the San Juan, the largest of which are the San Carlos and Serapiqui, both rising in the high lands of Costa Rica. The streams flowing in from the N. are comparatively small, indicating that the mountains are not far distant in that direction, and that upon that side the valley is narrow. The Serapiqui is ascended by canoes to a point about 20 m. above its mouth, where commences the road, or rather mule path, to San José, the capital of Costa Rica. About one third of the way from the lake to the ocean, on the S. bank of the river, are the ruins of the old fort or castle of San Juan, captured by the English in 1780. At one time, beside this fort, another at the head of the river (San Carlos), and a third at its mouth, the Spaniards kept up no fewer than 12 military stations on its banks. The width of the river varies from 100 to 400 yards, and its depth from 2 to 20 feet. It is interrupted by 5 rapids, viz.: Rapides del Toro, del Castillo, de los Valos, del Mico, and Machuca. The Machuca rapids are the largest, and in many respects the worst in the river. For the distance of nearly half a mile the stream is spread over a wide and crooked bed, full of large rocks projecting above the surface, between which the water rushes with the greatest violence. They are considered dangerous by the native boatmen, who are only enabled to ascend them by keeping close to the N. shore, where the current is weakest, and the bed of the river least obstructed. Here the *bongos*, or native boats, are pushed up by main force. The late transit company lost a number of their small steamers on these rapids, which, without great artificial improvement, must remain an insuperable obstacle to regular steam navigation on the river. The rapids of El Castillo are short, and deserve rather the name of falls. Here the water pours over an abrupt ledge of rocks, falling 8 feet in but little more than the same number of yards. Bongos are unloaded here, and the empty boats tracked past by men stationed here for the purpose. The steamers of the transit company did not attempt to pass these rapids, the passengers and merchandise being transferred by means of a tram road to vessels above. The remaining rapids, although formidable obstacles to navigation, do not require a special description. The banks of the San Juan for 20 m. from the lake, and for about the same distance above its mouth, are low and swampy, lined with palms, canes, and a variety of long coarse grass called *gamalote*. Elsewhere

the banks are generally firm, in some places rocky, from 6 to 20 feet high, and above the reach of overflows. They are everywhere covered with a thick forest of large trees, draped all over with *lianes* or woodbines, which, with the thousand varieties of tropical plants, form dense walls of verdure on both sides of the stream. The soil of the river valley seems uniformly fertile, and capable of producing abundantly all tropical staples. Like the Atrato, the San Juan river has formed a delta at its mouth, through which it flows for 18 m., reaching the sea through several channels. The largest of these is the Colorado channel, which opens directly into the ocean; the next in size is that which bears the name of the river, and flows into the harbor of San Juan. Between the two is a smaller one called Tauro. This delta is a maze of low grounds, swamps, creeks, and lagoons, the haunt of the manatee and alligator, and the home of innumerable varieties of water fowl. The port of San Juan (Greytown) derives its principal importance from the fact that it is the only possible eastern terminus for the proposed interoceanic canal, by way of the river San Juan and the Nicaraguan lakes. It is small but well protected, and until within the past year (1859) was easy of entrance and exit. The sea has now broken through the sand bank or spit, called Punta Arenas, which forms the outer protection of the harbor, and has filled up the former entrance, so that it carries only from 7 to 9 feet of water. Vessels now find it impossible to enter, and unless the obstruction is removed by art or the operation of natural causes, the port may be considered destroyed. On the Pacific the best port of the republic is that of Realejo, formerly Poesion, which is capacious and secure, but difficult of entrance. The little bay of San Juan del Sur is small and insecure, and scarcely deserves the name of harbor. The same may be said of the so called ports of Brito and Tamaranda. A good port is said to exist on Salinas bay.—The climate of Nicaragua, except among the mountains of Chontales and Segovia, is essentially tropical, but considerably modified by a variety of circumstances. The absence of high mountains toward the Atlantic, and the broad expanse of its lakes, permit the trade winds here to sweep entirely across the continent, and to give to the country a degree of ventilation agreeable to the senses and favorable to health. The region toward the Atlantic is unquestionably warmer, more humid, and less salubrious than that of the interior, and of the country bordering on the Pacific. The Nicaragua basin proper, within which the bulk of the population is concentrated, has two distinctly marked seasons, the wet and the dry, the former of which is called summer, the latter winter. The wet season commences in May and lasts until November, during which time, but usually near its commencement and its close, rains of some days' duration occasionally occur, and showers are common. The latter do

not often happen except late in the afternoon, or during the night. They are seldom of long continuance, and often days and weeks elapse, during what is called the rainy season, without a cloud obscuring the sky. Throughout this season the verdure and the crops, which during the dry season become sere and withered, appear in full luxuriance. The temperature is very equable, differing a little according to locality, but preserving a very nearly uniform range of from 78° to 88° F., occasionally sinking to 70° in the night and rising to 90° in the afternoon. During the dry season, from November to May, the temperature is lower, the nights are positively cool, and the winds occasionally chilling. The sky is cloudless, and trifling showers fall at rare intervals. The fields become parched and dry, and the cattle are driven to the borders of the streams for pasturage, while in the towns the dust becomes almost insufferable. It penetrates everywhere, sifting through the crevices of the tiled roofs in showers, and sweeping in clouds through the unglazed windows. This season is esteemed the healthiest of the year. Its effect is practically that of a northern winter, checking and destroying that rank and ephemeral vegetation which, continually renewed where the rains are constant as at Panama, forms dense, dank jungles, the birthplaces and homes of malaria and death. For the year ending September, 1851, the thermometer at the town of Rivas gave the following results: mean highest, 86.45°; mean lowest, 71.15°; mean average for the year, 77.42°; mean range, 15.3°. The amount of rain which fell from May to November inclusive was 90.3 inches; from December to April inclusive, 7.41 inches; total for the year, 97.71 inches. None fell in February, but 26.64 inches fell in July, and 17.86 inches in October.—The natural resources of Nicaragua are great, but they have been very imperfectly developed. The portion of land brought into cultivation is relatively small, but ample for the support of its population. There is no difficulty in increasing the amount to an indefinite extent, for the forests are easily removed, and genial nature yields rich harvests to the husbandman. There are many cattle estates, particularly in Chontales, Matagalpa, and Segovia, which cover wide tracts of country; some of these have no fewer than 10,000 or 15,000 head of cattle each. The cattle are generally fine, quite equal to those of the United States. Among the staples of the state, and which are produced in great perfection, are cacao, sugar, cotton, coffee, indigo, tobacco, rice, and maize or Indian corn. The sugar cane used in the country is indigenous, softer and smaller than the Asiatic varieties, but richer in juice. Two crops, and under favorable circumstances three crops a year are taken, and the cane requires replanting but once in 12 or 14 years. Cotton of excellent quality is grown in the country, and formerly as many as 50,000 bales were exported

annually. The export has now ceased. Cacao, only equalled by that of Soconusco, on the coast of Guatemala (which was once monopolized for the use of the royal household of Spain), is cultivated in considerable quantities. It is an article of general consumption among the inhabitants, and consequently commands so high a price that it will not bear exportation, even though it could be obtained in requisite quantities. Much time and great outlay are required in getting a cacao plantation into paying operation. Few have now the requisite capital; and these few are not likely, in consequence of the distracted condition of public affairs, to venture upon any investment. Under a stable condition of things, and by the opening of a steady and adequate channel to market, the cultivation of cacao would become of the first importance. The trees give two principal crops in the year. It is sold at \$15 to \$20 per quintal, while the Guayaquil is worth but \$5 or \$6. Indigo was formerly cultivated to a considerable extent, but has of late years much fallen off; and numbers of fine indigo estates in various parts of the republic have been abandoned. The plant cultivated for the manufacture of indigo is the *jiquilite* (*indigofera disperma*), an indigenous plant, the product of which is of a very excellent quality. The export of indigo from Nicaragua once amounted to 5,000 bales of 150 lbs. each. It is impossible to say what is its present amount; probably not more than from 1,000 to 2,000 bales. Wheat and the other cereals, as well as the fruits of the temperate zone, flourish in the elevated districts of Segovia and Chontales. In short, nearly all the edibles and fruits of the tropics are produced naturally, or may be cultivated in great perfection—plantains, bananas, beans, chile, tomatoes, breadfruit, arrowroot, okra, citrons, oranges, limes, lemons, pineapples, mamays, anonas or chirimoyas, guavas, cocoanuts, and a hundred other varieties of plants and fruits. Among the commercial vegetable productions may be mentioned sarsaparilla, annatto, aloes, ipecacuanha, ginger, vanilla, cowhage, copal, gum arabic, copaiba, caoutchouc, dragon's blood, and vango or oil paint. Among the valuable trees are mahogany, logwood, Brazil and Nicaragua wood, lignum vitae, fustic, yellow sanders, pine (on the heights), dragon's blood tree, silk-cotton tree, oak, copal tree, cedar, buttonwood, iron-wood, rosewood, and calabash. Of these, Brazil wood, cedar, and mahogany are found in almost inexhaustible quantities. The cedar is a large tree, like the red cedar of the north in nothing except color and durability; in solidity and other respects it closely resembles the black walnut. Five or six cargoes of Brazil wood were exported from Realajo yearly, and a larger quantity from San Juan. A quantity of cedar plank is also exported to South America. The raising of cattle and the production of cheese are important items in the actual resources of Nicaragua. The cheese is for common consumption, and great quanti-

ties are used.—The northern districts, Segovia, Matagalpa, and Chontales, adjoin the great metalliferous mountain region of Honduras, with which they correspond in climate, and with which they are geologically connected. They are rich in gold, silver, copper, iron, and lead, the ores of which are abundant and readily worked. Under the Spanish dominion, the mines of these districts yielded large returns; but they have greatly diminished, and, unless taken up by foreign enterprise, capital, and intelligence, are likely to fall into insignificance. No data exist for estimating the present value of their produce, but it probably does not exceed \$250,000 annually. It is stated that deposits of coal resembling anthracite have been found in Chontales, but the evidence on that point is not conclusive.—The commerce of Nicaragua is in a very depressed condition, and there are no data for calculating the imports or exports of the state with any degree of accuracy. The advance which the country made in these respects during the existence of the California transit, from 1850 to 1855, has been followed by more than a corresponding decline, the consequence of domestic dissensions and foreign invasion. The revenues of the country, derived from duties on imports, are merely nominal, and the support of government rests mainly on the returns of the taxes levied on tobacco and *aguardiente* or native rum, both of which are government *estancias* or monopolies. The republic has a considerable interior debt, and its proportion of the debt of the old federation, amounting to about \$500,000, remains as yet unpaid. With boundless natural resources, agricultural and mineral, a fine climate, and an unsurpassed geographical position, Nicaragua nevertheless now stands at the foot of the list of the Central American states in all that constitutes national prosperity. Education is at an exceedingly low ebb, and although both Granada and Leon have universities, they deserve to rank but little higher than the common schools of the United States.—The constitution is thoroughly republican in its provisions. The president is elective directly by the people, for the term of 2 years, and is ineligible for 2 consecutive terms. The legislative power is vested in an assembly consisting of a senate and house of representatives; the former is composed of 2 members from each of the departments into which the republic is divided, holding their office for 4 years. The representatives are apportioned on the basis of one for every 20,000 inhabitants; they hold their offices for 2 years, and are eligible for only 2 successive terms. The acts of the assembly require a vote of two thirds of each branch, and the approval of the president. All native-born males 20 years of age are voters; and married males, and persons who have obtained a scientific degree or acquired a liberal profession, have the privileges of electors at the age of 18. All persons convicted of criminal offences, who traffic in slaves, or accept

titles or employment from other governments, forfeit their citizenship. An individual who accepts the position of personal servant to another is incapable, for the time being, of exercising his political privileges. The Roman Catholic religion is recognized by the state, but the private exercise of all others is tolerated. Liberty of speech and of the press is guaranteed, but individuals may be arraigned for their abuse. The right of petition, inviolability of domicile, and security of seal are also recognized, and placed beyond the reach of the legislative and administrative powers. The judiciary consists of a supreme court, the members of which are named by the house of representatives and confirmed by the senate, 8 in each department, who hold their offices for 4 years, but are always eligible for reelection. One in each department is designated as presiding judge, and the president judges, meeting annually in the capital, constitute a court of appeal or final resort. Measures are now (1860) on foot for a revision of this constitution, which has been several times suspended during the troubles of the past 10 years; but it is not likely that it will be materially modified in the respects here indicated.—Nicaragua was discovered in 1521 by Gil Gonzales de Avila, who reached it by way of the Pacific, embarking at Panama. He penetrated from its southern extremity, at the head of a small force, to a point near the present site of Granada, where he encountered such large bodies of opponents that he thought it prudent to retrace his steps. On his return to Spain, with considerable booty, to secure reinforcements for the reduction of the country, Pedro Arias de Avila, the wily and unscrupulous governor of Panama, resolving to anticipate him in the enterprise, sent out to that region a large force under Francisco Fernandez de Cordova, who in 1522 founded the city of Granada on Lake Nicaragua, and subsequently in the same year the city of Leon on Lake Managua. Pedro Arias became the first governor of the country, and was succeeded by Rodrigo de Contreras, his son-in-law, who was soon recalled to Spain to answer charges of cruelty to the Indians. In his absence, his son Fernandez de Contreras revolted against the authority of the crown, and, after obtaining complete possession of the country, conceived the idea of separating the audiencia of Tierra Firme (now New Granada) and Peru from the Spanish dominion. He reduced Panama, and was on his way to capture Nombre de Dios, the key of the highway to Peru, when he encountered misfortunes which ended in his death. After this event, Nicaragua, attached to the captain-generalcy or audiencia of Guatemala, remained in general peace, disturbed only by occasional visits from the buccanniers, who penetrated into it from both oceans, until the outbreak of the revolution of 1821, which resulted in its independence, in common with that of the other provinces of the au-

diencia. This result was not accomplished without a severe struggle. The bishop of the province, supported by the more zealous adherents of the church, the aristocracy, and the officers of the crown, openly resisted the popular movement. A desperate contest ensued in the city of Leon, the capital, with every circumstance of ferocity and barbarism. Street was arrayed against street, and father against son. Partisans flocked in from the surrounding towns and ranked themselves with the contending factions. The contest was prolonged with varying success for 114 days, during which the best built portions of the city were destroyed; 1,000 houses, it is said, were burned in a single night. The struggle was finally ended by the intervention of the liberals of San Salvador, and Nicaragua took its place as the second state in importance in the federal republic of Central America, to which it remained attached until the formal dissolution of the republic in 1839. In the interval it suffered much from the partisan struggles which distracted the country, and which were kept up after the separation of the states, and with alternate success, by the rival factions. On the whole, however, the state adhered to what in Central America is called the liberal as distinguished from the servile party, and supported consistently the various plans that were suggested for reorganizing the federation. In 1847-'8 it became involved in a dispute with Great Britain regarding the Mosquito shore, but more particularly the port of San Juan del Norte, its only port on the Atlantic, which was seized by the British in Dec. 1847, under pretext that it belonged to the Mosquito king. In Jan. 1848, a Nicaraguan force descended the San Juan river, dispersed the small guard left by the English, and recaptured the port. When this circumstance became known in Jamaica, two British vessels of war, the *Alarm* and *Vixen*, under command of Capt. Loch, were despatched to San Juan, which was at once evacuated by the Nicaraguans, who retired up the river to a point near the mouth of the Serapiqui river, whither they were followed by the English, and routed with great loss. Capt. Loch pressed forward to Lake Nicaragua, and from the little island of Cabi, in front of Granada, dictated the terms of a convention, whereby Nicaragua agreed not to disturb the *status quo* of San Juan, over which she has since exercised no authority, although claiming her right of sovereignty. The dispute has now (1860) been settled by a treaty with Great Britain which constitutes San Juan a free port under the sovereignty of Nicaragua. In 1855 the country became involved in a civil war, and divided into two governments; the one, professing to be liberal, having its seat in Leon, the other in Granada. An obstinate struggle ensued between the factions, which finally resulted in favor of the liberals, who had meantime called in the aid of Col. William Walker of California, support-

ed by a considerable body of foreign adventurers. The decisive blow in the contest was the surprise of the city of Granada by Walker, Oct. 13, 1855. Soon after this event, dissensions arose between the successful party and its foreign auxiliaries; whereupon Walker, now promoted to the rank of general, assumed the supreme power under the title of president. For a short time, during which he received large accessions to his forces from abroad, his position seemed secured. But an attempt to establish slavery among a population, nine tenths of whom were of mixed blood, combined with the disaffection of the party which had invited him to the country, and the hostility of the holders of the route of interoceanic transit, whose rights he had annulled, rapidly undermined his power, which was finally completely overthrown by a coalition of the other states of Central America. Walker's force, reduced to fewer than 200 men, surrendered at Rivas, May 1, 1857, since which time the state has remained in comparative quiet, only interrupted by various unsuccessful attempts of Walker and his partisans to effect a lodgment in the country. At present, with her boundary dispute with Costa Rica settled, her rights over the Mosquito shore definitively recognized, and the rancor of local partisanship much softened down under the severe teachings of her past history, there seems to be no good reason, outside of the alleged incapacity of a mixed race for self-government, why Nicaragua should not assume her rank as the first state of Central America, to which she is entitled by her geographical position and her resources.

NICARAGUA, LAKE, a large body of fresh water occupying the heart of the republic of Nicaragua. It is 120 m. long, and varies from 80 to 50 m. in width. It has an elevation at mean stage of water of 111 feet 5 inches above low tide in the Pacific, from which it is separated on the W. by a low ridge or range of hills, which subside at one point to an elevation of but 48 feet above the lake level. The strip of land intervening between the lake and ocean varies from 12 to 30 m. in width. The lake has numerous tributaries, chiefly from the N., the largest of which are the rivers Mayales and Malacoloja. The streams falling into it from the S. are few and small, with the exception of the unexplored Rio Frio. It is connected with the superior Lake Managua by a narrow arm or *estero* called *Estero de Panaloya*, communicating with a short stream, frequently dry, called Rio Tipitapa, the proper outlet of Lake Managua. The N. E. trade winds from the Caribbean sea reach the lake, and when they are strong the waves become high, and roll in with all the majesty of the ocean. At such times, the water is piled up, as it were, on the southern shore, occasionally producing overflows of the low grounds. As the trade winds are intermittent, blowing freshly in the evening, and

subsiding toward morning, the waters of the lake seem to rise and fall accordingly; and this circumstance gave birth to the notion, entertained and promulgated by the early chroniclers, that the lake had a regular tide like that of the sea. Some of them imagined, in consequence, that it communicated with the ocean by a subterranean channel. The lake has a great number of islands, some isolated, but most in picturesque clusters, greatly diversifying its surface. The largest are Ometepe, Zapatero, and Solentanami. The first named is distinguished by two high volcanoes, from which it derives its name: *ome* in the Nahuatl or Mexican language signifying two, and *tepec*, mountain; i. e., island of the two mountains. Zapatero is now without inhabitants, but has extensive ruins, monolithic idols, and other evidences of a large ancient population. The volcano of Mombacho stands on the N. W. border of the lake, boldly projecting into the water. At its foot is a cluster of volcanic islets called the Corales, several hundreds in number and of surpassing loveliness. Indeed, the entire scenery of the lake, with its singular volcanic features, joined with the tropical luxuriance of the shores and islands, is equally remarkable for its grandeur and beauty. In these respects it is probably unrivalled by any similar body of water on the continent. Considered in an economic point of view, this lake is also invested with great interest. It is unquestionably the only body of water capable of supplying the summit levels of any canal that may be constructed across this continent; and whenever the requirements of commerce shall demand such a work, this circumstance must determine its course through Lake Nicaragua. The supply of water is amply sufficient for a canal of whatever dimensions called for by the exigencies of commerce. Observations made at the outlet of the lake, at its lowest stage of water in the year 1851, showed that the discharge was 715,800 cubic feet per minute. At the highest stage it was somewhat more than double that amount.

NICARAGUA WOOD. See BRAZIL WOOD.

NICARAGUAN INTEROCEANIC CANAL.

The project of uniting the Atlantic and Pacific oceans by means of a canal through the territories of Nicaragua, with the aids afforded by the river San Juan and Lake Nicaragua, began to be entertained as soon as it was found that there existed no natural water communication between the seas. As early as 1551, the historian Gomara had indicated the 4 lines which have since been regarded as offering the greatest facilities for the purpose, viz.: at Darien, Panama, Nicaragua, and Tehuantepec. There were difficulties, he said, "and even mountains in the way; but," he added, "there are likewise hands; let only the resolve be formed to make the passage, and it can be made. If inclination be not wanting, there will be no want of means; the Indies, to which the passage is to be made, will supply them. To a king of

Spain, with the wealth of the Indies at his command, when the object is the spice trade, that which is possible is also easy." But, although occupying so large a share of the attention of all maritime nations, and furnishing a subject for numerous essays in every language in Europe, yet it was not until after the discovery of gold in California that the question of a canal assumed a practical form, or that of its feasibility was accurately determined. In 1851 a complete survey was made of the river San Juan, Lake Nicaragua, and the isthmus intervening between the lake and the Pacific, by Col. Childs, under the direction of the "Atlantic and Pacific Ship Canal Company." Until then, it had always been assumed that the river San Juan, as well as Lake Nicaragua, could easily be made navigable for ships, and that the only obstacle to be overcome was the narrow strip of land between the lake and the ocean. Hence, all the so called surveys were confined to that point. One of these was made under orders of the Spanish government, in 1781, by Don Manuel Galisteo; another, and that best known, by Mr. John Bailly, under the direction of the government of Central America, in 1838. An intermediate examination seems to have been made early in the present century, the results of which are given in Thompson's "Guatemala." The following table shows the distances, elevations, &c., on the various lines followed by these explorers:

Authorities.	Distance from lake to coast.		Greatest elevation above sea level.	
	Miles.	Feet.	Feet.	Feet.
Galisteo, 1781	17	900	273	184
Quoted by Thompson	17	880	296	154
Bailly, 1838	16	780	615	487
Childs, 1851	18	588	150	47½

As the survey of Col. Childs is the only one which can be accepted as conforming to modern engineering requirements, it will be enough to present the detailed results at which he arrived. The line proposed by him, and on which all his calculations and estimates were based, commences at the little port of Brito on the Pacific, and passes across the isthmus between the ocean and the lake, to the mouth of a small stream called the Rio Lajas, flowing into the latter; thence across Lake Nicaragua to its outlet, and down the valley of the Rio San Juan to the port of the same name on the Atlantic. The length of this line was found to be 194½ miles, as follows:

	Miles.
Western Division—Canal from the port of Brito on the Pacific, through the valleys of the Rio Grande and Rio Lajas, flowing into Lake Nicaragua	18.588
Middle Division—Through Lake Nicaragua, from the mouth of the Rio Lajas to San Carlos, at the head of the San Juan river	54.500
Eastern Division—First Section: Slack water navigation on San Juan river, from San Carlos to a point on the river nearly opposite the mouth of the Rio Sarapiquí	90.900
Second Section: Canal from point last named to port of San Juan del Norte	98.505
Total, as above	194.993

The dimensions of the canal were designed to be: depth, 17 feet; excavations in earth, 50 feet wide at bottom, 86 feet wide at 9 feet above bottom, and 118 feet wide at surface of water; excavations in rock, 50 feet wide at bottom, 77 feet wide at 9 feet above bottom, and 78½ feet wide at surface of water. The construction of the canal on this plan contemplates supplying the western division, from the lake to the sea, with water from the lake. It would, therefore, be necessary to commence the work on the lake at a point where the water is 17 feet deep at mean level. This point is opposite the mouth of the Rio Lajas, and 25 chains from the shore. From this point, for a distance of 1½ m., partly along the Rio Lajas, the excavation would be principally in earth; but beyond this, for a distance of 5½ m., which carries the line beyond the summit, ¼ of the excavations would be in trap rock; that is to say, the deepest excavation or open cut would be 64½ feet (summit, 47½ feet - depth of canal, 17 feet = 64½ feet), and involve the removal of 1,800,000 cubic yards of earth, and 3,378,000 cubic yards of rock. The excavation and construction on this 5½ m. alone was estimated to cost upward of \$6,250,000. After passing the summit, and reaching the valley of a little stream called Rio Grande, the excavation, as a general rule, would be only the depth of the canal. Col. Childs found that the lake, at ordinary high water, is 102 feet 10 inches above the Pacific at high, and 111 feet 5 inches at low tide, instead of 128 feet, as calculated by Mr. Baily. He proposed to accomplish the descent to Brito by means of 14 locks, each of 8 feet lift. The harbor of Brito, as it is called, at the point where the Rio Grande enters the sea, is in fact only a small angular indentation of the land, partially protected by a low ledge of rocks, entirely inadequate for the terminus of a great work like the proposed canal, and incapable of answering the commonest requirements of a port. To remedy this deficiency, it was proposed to construct an artificial harbor of 84 acres area, by means of moles and jetties in the sea, and extensive excavations in the land. If, as supposed, the excavations here would be in sand, it would be obviously almost impossible to secure proper foundations for the immense sea walls and piers which the work would require. If in rock, as seems most likely, the cost and labor would almost surpass computation. Assuming the excavations to be in earth and sand, Col. Childs estimated the cost of these improvements at upward of \$2,700,000. Returning now to the lake, and proceeding from 17 feet depth of water, opposite the mouth of the Rio Lajas, in the direction of the outlet of the lake at San Carlos, there is ample depth of water for vessels of all sizes for a distance of about 51 m., to a point half a mile south of the Boacas islands, where the water shoals rapidly to 14 feet; for the remaining 5½ m. to San Carlos, the depth averages only 9 feet at low, and 14 feet at high water. For this distance,

therefore, an average under-water excavation of 8 feet in depth would be required, to carry out the plan of a canal 17 feet deep. But if the lake were kept at high level, the under-water excavation would have an average of only about 8 feet. Col. Childs proposed to protect this portion of the canal by rows of piles driven on each side, and supposed that when the excavation should be completed, there would be a sufficient current between them to keep the channel clear. We come now to the division between Lake Nicaragua and the Atlantic, through or along the Rio San Juan. Col. Childs carried a line of levels from the lake at San Carlos to the port of San Juan, and found the distance between those points to be 119½ m., and the total fall from the level of high water in the lake to that of high tide in the harbor, 107½ feet. From San Carlos to a point half a mile below the Serapiqui river, a distance of 91 m., Col. Childs proposed to make the river navigable by excavating its bed, and by constructing dams, to be passed by means of locks and short canals; the remaining 28 m. to be constructed through the alluvial delta of the San Juan, inland, and independently of the river. Of the whole fall, 62½ feet is on that portion of the river which he proposed to improve by dams, and on which there were to be 8 locks, and the remaining 45 feet on the inland portion of the works, by means of 6 locks—14 locks in all, each with an average lift of nearly 8 feet. It was proposed to place the first dam, descending the river, at the Castillo rapids, 37 m. from the lake, and to turn the falls thus created by the aid of a short lateral canal. By means of this dam the river was to be raised, at that point, 21½ feet, and the level of Lake Nicaragua 5 feet above its lowest stage; or, in other words, kept at high water mark, to avoid the extensive submarine excavations which would be necessary to enable vessels to enter the river. The fall at this dam would be 16 feet. The other dams were to be 4 of 8 feet fall, one of 18½ feet, and another of 14½ feet. Between all these it was found there would be required more or less excavation in the bed of the stream, often in rock. Col. Childs also proposed to improve the harbor of San Juan by means of moles, &c., and also to construct an artificial harbor or basin, in connection with it, of 18 acres area. As regards the amount of water passing through the San Juan, it was found that at its lowest level, June 4, 1851, the discharge from the lake was 11,930 cubic feet per second. The greatest rise in the lake is 5 feet. When it stood 3.43 feet above its lowest level, the flow of water in the river, at San Carlos, was 18,059 cubic feet per second, being an increase of upward of 50 per cent. Supposing the same ratio of increase, the discharge from the lake, at extreme high water, would be upward of 23,000 cubic feet per second. The river receives large accessions from its tributaries, which, at the point of divergence of the Colorado channel, swell the flow of

water to as much as 54,880 cubic feet per second, of which 42,056 cubic feet passes through the Colorado channel, and 12,824 cubic feet into the harbor of San Juan. Since the irruption of the sea (1859) into the harbor of San Juan, it is reported that the amount of water entering it from the river has been reduced to less than one third its former volume. The cost of the work was estimated by Col. Childs as follows:

Eastern division (from port of San Juan to lake) \$18,022,975
Central division (through lake) 1,088,410
Western division (from lake to Pacific)..... 14,475,000

Total \$33,587,385
Add for contingencies 15 per cent. 4,988,065

Total estimated cost..... \$38,575,450

The charter of the company, under the auspices of which the survey was made, stipulated that the canal should be of dimensions sufficient "to admit vessels of all sizes." A canal therefore, such as that proposed, but 17 feet deep and 118 feet wide at the surface of the water, could not meet the requirements of the charter, nor be adequate to the wants of commerce. To pass freely large merchantmen and vessels of war, a canal would require to be at least 80 feet deep, with locks and other works in proportion, which would involve at least three times the amount of excavation, &c., of the work proposed above, and a corresponding augmentation of cost, or a grand total of nearly \$100,000,000. A canal so small as to render necessary the transshipment of merchandise and passengers is manifestly inferior to a railway, both as involving, in the first instance, greater cost of construction, and, in the second place, greater expense in working, with less speed.—It has been proposed to reach the Pacific from Lake Nicaragua by other lines than that surveyed by Col. Childs. The first of these, by way of the river Sapoa to the bay of Salinas, has however been found to involve a summit cut of 119 feet in rock, an up lockage from the lake of 350 feet, and a down lockage to the Pacific of 432. The summit level moreover would be without any adequate supply of water, and this and other difficulties have proved the line to be impracticable, if not impossible. Another line has also been suggested, from the extreme upper end of Lake Nicaragua, through the Estero de Panaloya into Lake Managua, and thence by canal to the port of Tamarinda or of Realejo, or behind the volcanic range of the Marabios, through the Estero Real into the bay of Fonseca. These lines from Lake Managua have never been properly surveyed, but none of them are believed, by those best acquainted with the country, to offer any insurmountable engineering difficulties. The principal objection to these is the great length to which they would prolong the line of transit, expressed in the subjoined table, as compared with that from the mouth of the Rio Lajas to the indentation of Brito:

Routes from the port of San Juan to the Pacific.	Length of the Rio San Juan.	Distance on Lake Managua.	From Lake Nicaragua to Pacific.	Between Lakes Nicaragua and Managua.	Distance on Lake Managua.	Between Lake Managua and Pacific.	Actual Canalization.	Total km
To Brito.....	119	57	18	187	194
" Tamarinda	119	120	..	4	50	16	189	309
" Realejo	119	120	..	4	50	45	198	338
" Estero Real	119	120	..	4	50	20	143	313

It is assumed, throughout this table, that the river San Juan cannot be made navigable for ships, and that a lateral canal must be made for its entire length. The length of the river, including its windings, is nearly 120 m.; but it is probable that the distance in a right line between the lake and the Atlantic does not exceed 90 m.—The concession for constructing a canal through Nicaragua has been held by a great number of individuals and companies; but none have succeeded in carrying out the provisions of their contracts, which have consequently lapsed. The first was made to Messrs. Barclay and co. of London, Sept. 18, 1824; and was followed by others in the following order: to Aaron H. Palmer of New York, June 14, 1826; to the king of Holland, July 24, 1830; to Pedro Rouchaud of Paris, 1838; to George Holdship of New Orleans, 1839; to the king of Belgium, 1844; to Louis Napoleon Bonaparte (then a prisoner at Ham) in 1846; to William Wheelwright of London, Feb. 16, 1849 (not ratified by Nicaragua); to D. T. Brown of New York, March 14, 1849 (not ratified); to the American Atlantic and Pacific ship canal company, Aug. 27, 1849; and finally, May 1, 1858, to Felix Belly of Paris. No practical operations were undertaken by any of the concessionaries, except the Atlantic and Pacific ship canal company, which however were terminated with the survey conducted by Col. Childs. For the present, the entire project of a canal through Nicaragua seems to have been abandoned.

NICCOLINI, GIOVANNI BATTISTA, an Italian poet, born in San Giuliano, near Pisa, Dec. 31, 1785. He studied at the university of Pisa, and in 1807 was made librarian and professor of history and mythology in the academy of fine arts in Florence. The grand duke Ferdinand III. afterward appointed him librarian of the palace, but he soon resigned that office to resume his functions at the academy. His first tragedy, *Polissena*, was written in 1810 for the prize offered by the Tuscan academy. He published in the following years *Ino e Temisto*, *Medea*, *Edipo*, *Matilda*, *Nabuco*, and *Antonio Fiescarini*, which were received with great favor. His "Lessons on Mythology," written in his early life, were published in 1855. The publication of his "History of the House of Swabia" has been long delayed on account of illness, but is now (1860) said to be in progress. An edition of his works was published in Florence in 1847, but does not include two of his most celebrated plays, *Arnoldo da Brescia* and *Filippo Strozzi*.

NICE (Ital. *Nizza*), a former administrative division of Sardinia, situated between lat. 43° 37' and 44° 19' N., and bounded N. and E. by Piedmont, S. E. by the Mediterranean, and W. and S. W. by the French departments of Basses-Alpes and Var; area, 1,750 sq. m.; pop. in 1857, 258,608. It is subdivided into the 3 provinces of Nice (pop. 125,220), annexed to France in 1860, Oneglia, and San Remo. It entirely surrounds on the land side the little principality of Monaco. Geographically it belongs rather to France than to Italy, being separated from Piedmont by the Maritime Alps, branches of which extending toward the sea give great diversity to its surface. The principal river is the Var, which flows S. into the Mediterranean. The wild boar and antelope are found in the forests, and game is plentiful. The country, under proper cultivation, would be fertile. The vine, olive, and other fruits flourish on the sunny plains by the sea; grain, potatoes, and beans are grown; timber is abundant in some places; and the uplands afford good pasturage. Few cattle, however, are kept, the plough is little used, and the soil is not manured. Large quantities of honey are made, and there are some simple manufactures, such as coarse woollens and netting, soap, bronze and iron castings, and paper.—Nice, a seaport town and the capital of the preceding province, is built on a narrow plain between the Alps and the Mediterranean, and on both sides of the mouth of the river Paglione, 98 m. S.W. from Turin, in lat. 43° 42' N., long. 7° 17' E.; pop. 85,000. The port is small, but capable of admitting vessels drawing 15 feet of water, and is protected by two moles, one of which is surmounted by a battery and a lighthouse. The oldest part of the town lies on the E. side of the river, where the sailors' quarter is situated. It has narrow and dirty streets, but from its centre rises a hill 800 feet high, the summit of which, formerly occupied by a castle, is now laid out in public pleasure grounds, whence a magnificent prospect can be enjoyed. Parts of the old town have moreover been considerably improved of late years, and, as well as the more modern portion on the opposite side of the Paglione, present a gay and attractive appearance. The W. division is called the "quarter of the marble cross," from a monument commemorative of the reconciliation of Charles V. and Francis I. in 1538 through the intervention of Pope Paul III. It is inhabited chiefly by English, who have here a chapel and two cemeteries. The houses are neat and encompassed by gardens; and there are two public squares, one of which is surrounded by colonnades. The public buildings are not remarkable, the chief being a cathedral of the 17th century, a national college with a botanical garden attached to it, a public library, a zoological museum, a theatre, baths, hospitals, and convents. There are manufactories of silk, cotton, paper, oil, tobacco, perfumery, soap, and leather, and a considerable trade

in those articles and in wine and fruit.—Nice is a free port, and there are steamers twice a week to and from Marseilles and Genoa. It is chiefly noted as a watering place and resort for English invalids, who frequent it in such numbers that they have produced a complete change in the aspect of that part of the town which they inhabit. As many as 5,000 or 6,000 British visitors are found here in the winter, beside a large number of Russians, Poles, French, and Germans. The climate is remarkably mild and salubrious, and the suburbs, which lie among the low hills a mile or two inland, are said to be particularly delightful. In the month of February there is at times a sharp west wind called the *bise*, but the temperature is regular; there are no sudden changes, and the atmosphere is clear and pure. The mean temperature of spring is 64°, of summer 74°, of autumn 55°, and of winter 50°. The extremes are 84° and 32°. The language of Nice is a dialect of the Provençal called the Nizzard, which may be heard in its greatest purity in the neighboring rural districts. In the town French is generally spoken, and the vernacular is much corrupted.—Nice is built near the site of the ancient Ligurian town of Nicæa, founded by the Phœceans of Marseilles; and even after both became subject to the Romans it continued to be dependent for municipal purposes upon its parent city. It seems never to have been a place of much importance, being eclipsed by the neighboring town of Cemenelium, whose ruins may still be seen at Cimiez. In the 12th century Nice was the capital of an independent county, and in 1388 became a dependency of the house of Savoy. It was besieged by the Turks in 1543, and taken by Catinat in 1691, and by the duke of Berwick in the service of Louis XIV. in 1706. Having fallen into the hands of the French in 1793, it was incorporated with the department of the Maritime Alps, but was restored to Sardinia in 1814. By the treaty between Victor Emanuel and the emperor Napoleon III., March 24, 1860, Savoy and Nice were ceded to France, subject to the consent of the inhabitants to be given by ballot. The votes were taken in Nice on April 15, and resulted in a large majority in favor of annexation to France.

NICE, or NIOCEA (now *İznik*), an ancient city of Bithynia in Asia Minor, situated on the E. shore of Lake Ascania, 44 m. S. E. from Byzantium or Constantinople. It was colonized by Bottians, who called it Ancore, and having been destroyed by the Mysians was rebuilt after the death of Alexander the Great by Antigonus, who named it Antigonea. Lysimachus changed this appellation to Nicæa in honor of his wife. It became a place of great importance, and disputed with Nicomedia the title of metropolis of Bithynia. Under the Byzantine emperors it was long a bulwark against the Arabs and Seljooks, the latter of whom conquered it in 1078, 19 years after which it was taken from

them by the soldiers of the first crusade, but it was restored at the next treaty of peace. In 1204, Constantinople having become the seat of a Latin empire, Theodore Lascaris founded an empire at Nicæa, comprehending Bithynia, Mysia, Ionia, and a part of Lydia. He was succeeded by John Ducas Vatatzes (1222-'54), Theodore II. (1254-'8), John Lascaris (1258-'9), and Michael Palæologus, who in 1261 transferred the seat of power to Constantinople. In 1830 the city surrendered to Orchan, and was incorporated with the recently founded Ottoman empire.—Nice is celebrated in ecclesiastical history as the seat of a general council of the Christian church, which was called together by the emperor Constantine in order to settle the Arian controversy. According to the Roman Catholics it was the second, and according to Protestants the first of the general councils. It met in May or June, 325, and closed in July of the same year. It was attended by 318 bishops, but it is not known who presided, as no complete record of the proceedings has been preserved. The principal authorities for the doings of the council are Athanasius, who accompanied his bishop in the capacity of archdeacon, and Eusebius, bishop of Cæsarea. Constantine himself was present, and took an active part in the transactions of the assembly. There seem to have been present at the council three parties: the adherents of Arius, who were very few in number; the Homoousians, his most direct opponents, who were also a minority of the eastern church; and a party which occupied a middle ground, and from which afterward sprang the Semi-Arians. It was the wish of these last that the controversy should be composed by the adoption of some general formula, which would still leave each party free to hold most of its own opinions. The Homoousians, however, insisted upon an unqualified condemnation of Arius, and a declaration of the belief of the church in an identity of essence between the Son and the Father. Their views finally prevailed, and the result was the adoption of the celebrated formula of faith which completely established the heterodoxy of the Arian views. This creed, however, is not the one which is now used in the Roman Catholic, Anglican, Episcopal, and Lutheran churches under the name of Nicene, though the latter embodies all its articles. The Nicene creed is an amplification of the one made at Nice, and was drawn up at Constantinople in 381. When the formula was adopted at Nice, 17 bishops at first refused to subscribe to the determination of the majority, but all of them afterward assented except two. Arius was banished into Illyricum, deposed from his office, and excommunicated. According to the Latin writers the council passed in all 20 canons, but the oriental Christians extend the number to 80. The controversy respecting the celebration of Easter was terminated, the Novatian dispute concerning the readmission of apostates to com-

munion was composed, the Meletian schism was censured, and certain questions of ecclesiastical discipline were settled. The bishops were also about to impose celibacy on the clergy by an express law, but they were dissuaded from doing so by Paphnutius, who was himself living in that state.—The second council of Nice, which is recognized as œcumenical only by the Roman Catholics, is the 8th, or according to Protestants the 7th in order of time of the church councils, having been held in 787. It assembled under the authority of Pope Adrian I. by the desire of the empress Irene, and sat from Sept. 24 to Oct. 28. The bishops declared the veneration of images and the cross to be agreeable to Sacred Scripture and reason and to the teachings of the church, and penalties were denounced against all who should maintain the opposite doctrine.

NICENE CREED. See NICE.

NICÉRON, JEAN PIERRE, a French author, born in Paris in 1685, died in 1788. He was a member of the order of Barnabites and a relative of Jean François Nicéron, the writer on optics and friend of Descartes. After teaching Latin and rhetoric for some time in provincial colleges, he devoted himself to the preparation of his *Mémoires pour servir à l'histoire des hommes illustres de la république des lettres, avec un catalogue raisonné de leurs ouvrages* (48 vols. 12mo., Paris, 1727-'45), the last 4 volumes of which were published by Père Oudin, Michault, and the abbé Goujet. The work is valuable as a source of information, but has slight literary merit.

NICHOL, JOHN PRINGLE, a Scottish astronomer, born in Montrose about 1804, died in Rothesay, Sept. 19, 1859. He was the son of a bookseller, and at the age of 16 taught school at Dun, not far from Montrose. Subsequently he studied for the ministry, and was licensed to preach, but his taste for scientific pursuits led him to give up his profession. By Lord Melbourne's ministry he was appointed professor of practical astronomy in the university of Glasgow, which station he continued to hold until his death. He was very successful as a popular lecturer on his favorite science, in which capacity he spent some time in the United States. He wrote "The Architecture of the Heavens" (8vo., 1838); "Contemplations on the Solar System" (8vo., 1844); "Thoughts on some Important Points relating to the System of the World" (8vo., Edinburgh, 1846); "Exposition and History of the Planet Neptune" (8vo., 1848); "The Stellar Universe: Views of its Arrangements, Motions, and Evolutions" (12mo., 1848); "The Planetary System, its Order and Physical Structure" (8vo., London, 1851); "Cyclopædia of the Physical Sciences" (8vo., 1857). His writings are clear and frequently eloquent.

NICHOLAS. I. A W. co. of Va., intersected by the Gauley river, a branch of the Great Kanawha, and drained by Meadow river and Buffalo creek; area, 880 sq. m.; pop. in 1850,

3,963, of whom 73 were slaves. It has a mountainous surface and a soil not generally productive. The productions in 1850 were 83,273 bushels of Indian corn, 31,877 of oats, 6,209 of wheat, 2,001 tons of hay, 2,670 lbs. of tobacco, 13,649 of wool, and 41,976 of butter. There were 20 grist mills, 5 saw mills, 2 tanneries, 9 churches, and 189 pupils attending public schools. Value of real estate in 1856, \$1,841,294, being an increase since 1850 of 69 per cent. Capital, Summerville. II. A. N. E. co., of Ky., intersected by Licking river and drained by its branches; area estimated at 800 sq. m.; pop. in 1850, 10,861, of whom 1,513 were slaves. It has a diversified surface, rugged in the N. and undulating in the S., the latter portion being very fertile. The productions in 1850 were 733,750 bushels of Indian corn, 69,834 of oats, 100,280 lbs. of tobacco, 82,268 of wool, and 161 tons of hemp. There were 19 grist mills, 7 saw mills, 3 tanneries, 13 churches, and 1,068 pupils attending public schools. The Blue Lick spring, celebrated for its mineral waters, is in this county on the banks of Licking river. The county will be traversed by the Maysville and Lexington railroad, now constructing. Capital, Carlisle.

NICHOLAS I. (NICOLAI PAVLOVICH), emperor of Russia, born in St. Petersburg, July 7, 1796, died there, March 2, 1855. He was the 8d son of Paul I. by his second wife, a daughter of the duke Eugene of Württemberg, and was educated under the direction of his mother, who was a virtuous, thoughtful, and domestic German woman. Among his tutors were Count Lambdorf, Muravieff, Adelung, and the political economist Storch. With the exception of political economy, he showed comparatively little interest in scientific attainments, but was quick in mastering foreign languages. He grew up during the time of the wars of Napoleon, which tended to increase his natural taste for military life. The fondness for the pomp of parades, the minute attention to the external appearance of the soldiers, the passion for witnessing military exercises and manœuvring, which marked the rest of his life, became manifest in his early youth; and from the peace in 1815 to his accession in 1825 he devoted himself almost exclusively to military matters, without however giving evidence of any real strategical capacity. During this part of his life he contracted a passion for drumming, and considered himself a virtuoso in this art, to the great annoyance of those around his person. Nicholas believed likewise that he had a great capacity for painting, especially battles, but never accomplished any thing respectable in that department. In 1816 he visited England and other foreign countries and the Russian provinces. On July 13, 1817, he married Charlotte of Prussia (Alexandra Feodorovna), the eldest daughter of Frederic William III.; she gave birth on April 17 (29 O. S.), 1818, to the present emperor Alexander II. About 1821 the family pact was secretly agreed upon,

by which his elder brother Constantine renounced the succession in his favor. Nicholas, however, on the news of the death of the eldest brother, the emperor Alexander I. (Dec. 1, 1825), together with the whole nation, took the oath of allegiance to Constantine, and did not assume the reins of power until the latter, who then resided at Warsaw, had publicly signified his determination not to reign. The accession of Nicholas to the throne became the signal of a formidable insurrection, in the prompt suppression of which the new emperor showed great personal courage and presence of mind, but at the same time a cold-blooded and unrelenting disposition. Capital punishment, which had been abolished by the empress Elizabeth, was revived by Nicholas for the purpose of inflicting it upon the 5 principal leaders of the insurrection. Four were publicly executed, one after another, in St. Petersburg. The 5th and last in order was the poet Rileyeff. The rope broke, and he fell to the ground still alive. The sight of his agony created such a degree of sympathy in the assembled multitude, that the governor-general sent for instruction to the emperor. The command of Nicholas was: "Take a stronger rope and proceed with the execution." The other parties to the insurrection were banished to Siberia, some for life, and others for 20 years or for shorter periods; but the sentence of none of them was ever commuted. The insurgents declared that they were prompted to their attempt by the desolate condition to which the latter part of the reign of Alexander I. had reduced the empire, by the ferocious disposition of Constantine, and by the supposed incapacity of the new emperor. Nicholas, who was present during the examination of the prisoners, hidden behind a screen, thus received a wholesome lesson; and his first endeavor was to labor for the moral and social regeneration of the country. The brilliant though dearly purchased victories of Paskewitch and Diebitch over Persia and Turkey in 1828-'9 contributed to add prestige to his government, especially as the Turkish war also saved the independence of struggling Greece, as well as that of the Danubian principalities, which were now reorganized under a Russian protectorate. The revolution of 1830-'31 in Poland, threatening at first to complicate the foreign relations of Russia, terminated in the annihilation of Polish nationality, and the absorption of that country in the empire of the czar. These events, accomplished in rapid succession, surrounded Nicholas with a halo of glory. His attempt to develop the native energies of the Russian nation, and to oppose the foreign influences which under Catharine II. and Alexander I. had hindered the progress of the national genius, constituted the origin of the so called Russian governmental Pan Slavism; and many strong and active intellects, attracted by the earnestness of his patriotic efforts, rallied at that time under his banner. He even for some

time relaxed the rigor of the censorship, combated the venality of public men, and ordered the codification of the laws. But this reformatory zeal was of short duration. His want of discrimination in the selection of his ministers, the adulations of courtiers at home and of despotic sovereigns abroad, and the temptations of power, caused him to relapse into the most rigid absolutism; and Russia soon presented again the spectacle of a vast empire ruled by the iron hand of a single man, whose power rested upon a colossal military organization pervading all branches of the administration, and upon the blind agency of servile ministers. The erection of the citadel of Warsaw and numerous other fortifications served to keep down Poland. The United Greeks, a body who acknowledged the authority of the pope while preserving the usages of the Greek church, were compelled to join the orthodox establishment; the Protestants of the Baltic provinces were persecuted; and the Jews were subjected to the most barbarous treatment. His influence on the affairs of Europe from 1830 to 1840 was not very conspicuous, although he more and more menacingly observed the growth of liberal ideas. He indirectly supported Don Carlos in Spain, but considered Dom Miguel of Portugal as a usurper. To the last he opposed the introduction of constitutions in Greece and Prussia. After the crushing of Poland he drew closer his alliance with Austria and Prussia. With England he endeavored to remain on terms of good will, though not of close amity; but he was opposed to the July monarchy in France. During the political complications in connection with the conflict between the viceroy of Egypt Mehemet Ali and the sultan, Nicholas succeeded in securing his predominance in the East by a speedy intervention against the advance of Ibrahim Pasha in 1833, and in maintaining peace with the western powers in 1840. In 1844 he paid a visit to Queen Victoria, and subsequently he visited the emperor of Austria, and in 1846 Pope Gregory XVI. The attempted Polish rising of 1846 was suppressed with little bloodshed within the limits of the Russian parts of that country. He abstained from interfering during the political excitement which preceded and followed the French revolution of 1848, except in the Danubian principalities, until his assistance was invoked by Francis Joseph against the Hungarians, whose revolution was crushed by the aid of Russian troops, Görgey surrendering his army at discretion to the Russian general Rüdiger, acting under the command of Paskewitch, at Világos, Aug. 13, 1849. In the East Nicholas followed from the beginning of his reign the traditions of his house in his wars of conquest in Persia, the Caucasus, and Turkey. The war against the Circassians and other Caucasian tribes, who found an eastern Abd el Kader in Shamy! Bey, cost numberless troops and millions of money, but was at the same time an excellent military school

for the empire. Nicholas's ambition of gaining preponderance in Turkey was constantly perceptible during his reign, and led in 1853, on occasion of the controversy about the guardianship of the holy places at Jerusalem and the protectorate over the Danubian principalities, to the rupture with England and France, which resulted in the Crimean war. In the spring of 1853 he had an interview with the emperor of Austria at Olmütz; but subsequently during the war the latter concluded a treaty with the allies (Dec. 3, 1854), occupied the Danubian principalities, and concentrated a large army in Galicia. Nicholas was left alone to fight the combined armies of France, England, Sardinia, and Turkey. The repeated defeats and losses of his formidable armies and fleets produced a deep effect upon his powerful constitution, and hastened his death, the more immediate cause of which was atrophy of the lungs. For some time previously he had been violently affected with influenza. He became worse by degrees from want of sleep and increased cough; but notwithstanding the remonstrances of his physicians (Dr. Mandt and Dr. Karell), he continued to attend to his usual occupations, and on Feb. 22 inspected some troops who were about to march into Lithuania. In the evening he was present at the prayers for the first week of Lent, but complained of being cold. From that evening he did not quit his little working room. On Feb. 23 he sent for his adjutant, Col. Tettenborn, and despatched him to Sebastopol. During the whole time he was ill, he lay on his camp bed, consisting of a casing of Russian leather filled with hay, a bolster of the same kind, with a blanket and his cloak over him. It was not till Feb. 28 that his state was looked on as decidedly serious. From that time he became rapidly worse; the physicians apprehended a paralysis of the lungs, and despaired of his recovery on the evening of March 1. He calmly received the report of the physicians in regard to his critical condition, and took the last sacraments early on the morning of March 2. He then took leave of the empress, their children and grandchildren, and blessed each one of them with a firm voice. He next sent for Counts Orloff and Adlerberg and Prince Dolgoruki, thanking them for their fidelity and bidding them farewell. Subsequently he took leave of the servants immediately about his person, on which occasion he is said to have been much affected. Last of all Madame Rohrbeck, the lady in waiting of the empress, was sent for, whom he begged never to quit her mistress. While his father confessor was speaking to him, he took the empress's hand and put it into the priest's. After this he lost his speech for a while, during which time he was engaged in prayer and crossed himself repeatedly. He subsequently regained his voice and spoke from time to time up to his decease, which took place without a struggle in the presence of the whole family at 10 minutes past noon. Among the last articulate words that

the emperor spoke to his wife were: *Dites à Frite* (the empress's brother, King Frederic William IV. of Prussia) *de rester toujours le même pour la Russie, et de ne pas oublier les paroles de papa.*—Nicholas was of a commanding presence, and the glance of his large, clear, cold, blue-greenish eyes pierced through and through. His capacity for labor and endurance was immense. He travelled day and night to inspect fortresses and review troops, and he worked at times 14 or 16 hours a day. His temperance and frugality were as remarkable as his industry; and an extra glass of wine at dinner excited him beyond measure. His habits were ostentatiously simple and dramatically soldier-like. He demanded that outward signs of awe should encounter him wherever he went, and to create a prestige was the constant object of his anxiety, whether he was walking the streets of his own capital or visiting foreign countries. The church, the army, and the secret police were the great engines of his government. He governed the holy synod by the medium of an aide-de-camp, whom he appointed as its president. In the latter part of his reign he suppressed liberal studies and systematically discouraged all liberal literature, while the universities of the empire, maintained with great ostentation, were devoted to educating men in sciences useful in war or in the administration of public affairs. He desired to abolish serfdom, but had neither the capacity nor the resolution necessary to carry out the measure. Although strenuously opposed to the liberty of the press in Russia, he is said to have daily perused the principal newspapers of England and the continent, and to have been very sensitive to their strictures upon his person or policy. Though kind to his attendants and lavish in his rewards for personal services, his disposition was cruel and tyrannical, and throughout his life he never learned to act up to the Russian proverb: "Be unyielding in punishing; be great in pardon." He was an excellent husband and father; and in his domestic virtues as well as in his religious fulfilment of his promises, he imitated the example of his mother. No Muscovite sovereign ever succeeded in inspiring his subjects with a more fanatical attachment to his person; and wherever the lofty stature and imperial port of Nicholas appeared, he was hailed as a demi-god rather than a man. His pride rose with his power, and at times he seemed possessed with hallucinations of almost superhuman greatness.—Beside his eldest son and successor, Alexander II., his children are: Maria (born 1819), widow of the duke of Leuchtenberg; Olga (1822), wife of the crown prince of Würtemberg; Constantine (1827), high admiral; Nicholas (1831), and Michael (1832). The widow of Nicholas died in St. Petersburg, Nov. 1, 1860.

NICHOLAS, SAINT, bishop of Myra, born in Panthera in Lycia, died Dec. 6, 326. He is one of the most popular saints of Catholic Europe, being invoked as the patron of sailors,

travellers, and captives, and the guardian of unmarried girls and of children. The young are universally taught to revere him, and the popular fiction which represents him as the bearer of presents to children on Christmas eve is well known. He is the Santa Claus of the Dutch. He takes rank in the Greek church immediately after the great fathers. Justinian dedicated a church to him in Constantinople about 560; he has been revered in the West since the 10th century, and became one of the favorite patron saints of Italy and northern Europe about the beginning of the 12th century. One of the most characteristic legends of him is that when a certain nobleman was about to prostitute his 8 daughters because he was too poor to give them marriage portions, St. Nicholas threw 8 purses in at his window by night, and thus enabled the daughters to be respectably married. His supposed patronage of children may be traced to the following story. During a scarcity of food he was once entertained by a man who used to steal children and serve up their limbs to be eaten by his guests. But when the dish was set before the saint he detected the fraud, and going to the tub where the remains of the children were salted down, he made over them the sign of the cross, and they rose up whole and well.

NICHOLS, ICHABOD, D.D., an American clergyman, born in Portsmouth, N. H., July 5, 1784, died in Cambridge, Mass., Jan. 2, 1859. He was graduated at Harvard college in 1802, and commenced the study of theology with the Rev. Dr. Barnard of Salem, but returned to Cambridge in 1805 as tutor in mathematics, and remained in that office for 4 years. On Jan. 7, 1809, he was ordained as associate pastor with the Rev. Dr. Deane of the first Congregational church in Portland, Me.; in 1814 he became sole pastor by the death of his senior, and continued so till 1855, when he received a colleague. After this event, still retaining his pastorate, he removed to Cambridge, where he pursued his favorite studies and literary labors, with waning health, but with undiminished vigor of mind and tenacity of purpose, till within a few days of his death. He received the degree of D.D. from Bowdoin college in 1821, and from Harvard college in 1831. He was for many years one of the trustees of Bowdoin college, and in that capacity rendered large and efficient aid to its administration by his wise counsel and judicious influence. He was early elected a member, and was for several years the vice-president of the American academy of arts and sciences. Dr. Nichols retained through life his strong predilection for mathematical science, and was conversant with the successive stages of progress in that and the cognate departments of research. He was profoundly versed in metaphysics and ethics, and was a bold and independent thinker. In his theological views he was a Unitarian of the more conservative school. In 1830 he published a work on natural theology, which con-

tains many views and illustrations peculiarly his own. He left a work nearly ready for the press, entitled "Hours with the Evangelists," which embraces an argument for the Christian revelation and miracles, directed mainly against the Straussian theory, and a series of critical and philosophical comments on the principal epochs in the life of Jesus. Of this work the first volume appeared in 1859 (8vo., Boston), and a second will be issued in the course of 1861. A volume entitled "Remembered Words from the Sermons of the Rev. I. Nichols" appeared in Boston in 1860.

NICHOLS, JOHN, an English printer and author, born in London in 1745, died in 1826. At an early age he was apprenticed to the learned printer William Bowyer, became his partner on coming of age, and succeeded to the entire business on his death in 1777. His "Biographical and Literary Anecdotes of William Bowyer, Printer, F.S.A., and of many of his Learned Friends" (4to., 1782), was recast and extended to 9 vols. 8vo. under the title of "Literary Anecdotes of the Eighteenth Century" (1812-'15), and the series further continued by himself and his son, John Bowyer Nichols, under that of "Illustrations of Literary History" (8 vols. 8vo., 1817-'58). He also wrote or edited many works on English antiquities and local history, and was from 1778 till his death the editor and publisher of the "Gentleman's Magazine," in which he was succeeded by his son. There is a memoir of him, by Alexander Chalmers, in the last volume of the "Illustrations of Literary History."—JOHN GOREN, grandson of the preceding, born in London about 1807, is likewise noted for his acquaintance with antiquarian and topographical matters, and has been for many years connected as editor or publisher with the preparation of a great number of works, including several for the Camden society. In 1849 he published a translation of Erasmus's "Pilgrimage to St. Mary of Walsingham," and edited in 1852 the "Literary Remains of J. S. Hardy." He was for many years a manager of and chief contributor to the biographical department of the "Gentleman's Magazine." Since 1856 he has edited for that periodical the "Correspondence of Sylvanus Urban," which abounds in interesting antiquarian details and in literary anecdotes and gossip. This "Correspondence" still continues (1860), and was preceded in 1856 by Mr. Nichols's "Autobiography of Sylvanus Urban," which relates the early history and reminiscences of the magazine.

NICHOLSON, ALFRED OSBORN POPE, an American journalist and senator, born in Williamson co., Tenn., Aug. 31, 1808. In 1827 he was graduated at the university of North Carolina, at Chapel Hill, and commenced the study of medicine; but he abandoned that profession for the law, and obtained license to practise in 1831. In 1832 he became editor of the "Western Mercury," a democratic newspaper published at Columbia, Tenn., which he conducted for 8

years. He was elected to the legislature of Tennessee in 1833, 1835, and 1837; and in 1839 he was nominated for congress, but declined the nomination. He served as candidate for presidential elector in 1840, on the democratic ticket. In Dec. 1840, he was appointed by Gov. Polk a U. S. senator, to fill a vacancy occasioned by the death of Felix Grundy, and served for two sessions, one of which was the extra session of 1841. In 1843 he was elected to the state senate, and the next year took an active part in the presidential canvass in favor of Mr. Polk. In Dec. 1844, he removed from Columbia to Nashville, and took charge of the "Nashville Union." At the meeting of the legislature in Oct. 1845, he was nominated for U. S. senator, but defeated. In 1846 he retired from the editorship of the "Union," and was president of the bank of Tennessee from 1846 to 1848. He was a member of the southern convention which met at Nashville in 1850, and delivered in that body an elaborate speech in favor of the "compromise measures" then before congress. In 1851 he was appointed by the governor to the office of chancellor for the middle district of Tennessee, to fill a vacancy. This post he held until the meeting of the legislature in Oct. 1851, when he refused to be a candidate for election. He was a member of the democratic national convention of 1852, and a candidate for presidential elector for the state at large on the Pierce and King ticket. Upon the accession of Gen. Pierce to the presidency, Mr. Nicholson was offered an appointment in the cabinet, but declined the position, and was editor of the "Washington Union" during President Pierce's administration. In Oct. 1857, he was elected to the U. S. senate for a full term commencing March 4, 1859. Though Mr. Nicholson has from his youth been an active politician, he was a regular and successful practitioner at the bar for nearly 20 years.

NICHOLSON, JAMES, an American naval officer, born in Maryland in 1737, died in New York, Sept. 2, 1804. His first appointment was in June, 1776, to the command of the Virginia of 28 guns; and in Jan. 1777, he succeeded Commodore Esek Hopkins as commander-in-chief of the navy, and held that position until its dissolution. A vigilant blockade of the Chesapeake prevented the Virginia from getting out of the bay, and Capt. Nicholson and his crew joined the army, and were present at the battle of Trenton. Subsequently in attempting to go to sea the Virginia struck upon the middle ground near the mouth of the Chesapeake, lost her rudder, and was captured by a very superior British force, Capt. Nicholson escaping with part of his crew. An inquiry instituted by congress acquitted him of all blame. He afterward commanded the Trumbull frigate of 78 guns, in which ship he was captured in Aug. 1781, off the Delaware, by the British frigate Iris, 32, and General Monk, 18. The Trumbull made a most gallant resistance, and did not surrender until she was completely dis-

mantled and had sustained a heavy loss in killed and wounded. Com. Nicholson was not exchanged until near the close of the war, and did not serve afloat again.—SAMUEL, brother of the preceding, was also a commodore in the navy of the revolution, served in command of the *Deane*, 82, and was the first commander of the frigate *Constitution*. He was born in Maryland, and died in 1811 while senior officer of the navy.

NICIAS, I. An Athenian general, who flourished in the latter part of the 5th century B. C. He was several times associated with Pericles in military command, gaining a reputation for prudence and incorruptibility; and on the death of Pericles he was chosen by the aristocracy as their political leader in opposition to Cleon and the democrats. When Cleon proposed a decree punishing the inhabitants of Mitylene for rebellion, by putting to death the men and reducing the women and children to slavery, Nicias and his party opposed it with all their influence. He early gained a reputation for mildness, liberality, and piety; but his timidity, reserve, and superstition made him an object of ridicule to the comic poets of the day. He sacrificed every day, associated much with the prophets, and kept a soothsayer in his own house, in order that he might know the will of the gods in regard to his private affairs. In war he was distinguished rather for prudence than genius, but was almost always successful. He conquered the island of Minoa in 427 B. C., ravaged the island of Melos and the Locran coast in 426, gained a victory over the Corinthians, (who were among the most prominent enemies of Athens in the Peloponnesian war) on their own territory in 425, and in conjunction with two colleagues captured the island of Cythera, belonging to Laedæmon, in 424. But Nicias was naturally inclined to peace, and on the death of Cleon negotiations were entered into and a treaty was concluded with the Spartans, called the peace of Nicias. A defensive alliance between Athens and Sparta was soon after proposed, and confirmed on the part of the Spartans; but dissatisfaction having arisen because Argos had been induced by Alcibiades, who was now beginning to take part in public affairs, to send an embassy to Athens, it required all the energy of Nicias to preserve the existing treaties. Nicias and Alcibiades were now open rivals, and the demagogue Hyperbolus strove to procure the banishment of one or the other of them; but through their united efforts Hyperbolus himself was ostracized. In 416 the Athenians, in spite of the opposition of Nicias, resolved to send an expedition into Sicily. Nicias, Alcibiades, and Lamachus were appointed to the command; but Alcibiades was soon afterward recalled, Lamachus was slain before Syracuse, and Nicias was left to conduct operations alone. At first he was successful. Syracuse was in hourly danger of falling into his hands, when

the Spartan commander Gylippus arrived with succor for the besieged. Nicias sent home for reinforcements and permission to resign. The reinforcements were despatched under Demosthenes and Eurymedon, but the second request was refused, and Nicias continued the war, but with constantly failing fortunes. Yielding to the representations of his colleagues, he was about to retreat when an eclipse of the moon occurred, and was interpreted to the superstitious commander as an injunction from the gods to remain until the next full moon. The delay proved fatal. The Syracusans forced the Athenians to a general naval engagement, destroyed their fleet, and when they attempted to escape by land pursued and captured them. Nicias and Demosthenes were put to death, and the Athenians refused to inscribe the name of the former upon the monument which they raised to the memory of those who fell in Sicily. II. An Athenian painter, who flourished about 320 B. C. He was famous in particular as a painter of female figures in encaustic. He assisted Praxiteles in coloring his statues. He was the first painter who used burnt ochre, or enamelled his pictures with fire, the exact method of which is not now understood.

NICK, OLD, a popular name of the devil. Though Butler in "*Hudibras*" derives the term from the name of Nicolo Macchiavelli, there is no doubt of its being in use before his time, and of its coming very early into England from the north. The Icelandic *neek* or water spirit is called *Nikur*, one of the Eddaic names of Odin; and a belief in similar beings is common to all the Scandinavian races. Burns alludes to this name under the form of "*Nickie-ben*" in his "*Address to the De'il*."

NICKEL, a brilliant, ductile, and malleable metal, discovered in 1751 by Cronstedt. It is represented by the symbol Ni; its equivalent, as determined by Schneider in 1859,* is 29, and its specific gravity when forged 8.82. It is more fusible than iron, and like that is rendered still more so by combination with carbon. It is also magnetic at temperatures below 680°. Needles for the compass made of it have this advantage over those of steel, that they are not liable to rust. Its tenacity is greater than that of iron. The useful qualities possessed by this metal would seem to adapt it for many important purposes in the arts if it were more generally known, and could be obtained in large quantities. Nickel and cobalt are commonly associated together, and also with iron, both in their ores and in meteoric iron. The three metals present several remarkable points of resemblance, and suggest a relationship that is as yet very imperfectly understood. The sources of supply of nickel are the substance called *speiss*, an arseniuret of nickel obtained

* The same authority makes that of cobalt 30; so that the equivalents of the two metals, and that of iron (26), form a regularly ascending scale, beginning with the last. That of manganese, as determined by Von Hauer, is 27.5.

in the manufacture of smalt (see COBALT), and the native arseniuret of nickel called *Kupfernickel* (copper nickel) by the German miners, which when pure contains 56 per cent. of arsenic and 44 per cent. of nickel. One or more other metals, as iron, lead, cobalt, copper, and antimony, together with sulphur, are commonly present in small quantities. Mines producing nickel are worked in Saxony, Thuringia, Hesse, Styria, Dauphiné, and Sweden. In the United States its ores have been found in Chatham, Conn., and are worked in Lancaster co., Penn., where from the reports of the mine it is found in almost inexhaustible quantities associated with copper, and also occurring in the form of sulphuret of nickel. It is this locality which furnishes the nickel for the new American cent, of which 12 parts in 100 are nickel and 88 parts are copper. In Bavaria it has also been applied to coinage. In the mineral cobalt pyrites, the composition of which is expressed by the formula $\text{CoS} + \text{Co}_2\text{S}_3$, the cobalt is sometimes replaced in part by nickel or by copper; and the variety of this species called siegenite, the composition of which may be represented by the formula $(\text{Ni}, \text{Co}, \text{Fe})\text{S} + (\text{Ni}, \text{Co}, \text{Fe})_2\text{S}_3$, sometimes contains from 33 to more than 42 per cent. of nickel. This variety occurs at Mine la Motte, Missouri, and has been met with in Carroll co., Md. Prof. Wurtz of Washington reported to the American association for the advancement of science in 1858 his discovery of ores of a similar character in the gold region of North Carolina; in Gaston and Lincoln cos. they are especially abundant, along the western slope of Cross mountain, where the fragments present the appearance of a black earthy wad or gossan, and cover the surface of the ground. (See "American Journal of Science," Jan. 1859).—Nickel is chiefly valued as an ingredient of the alloy German silver, the best of which is composed of nickel 3 parts, zinc 3½, and copper 8. An alloy made by the Chinese and sometimes called *tutenag* contains, with the quantities of nickel and copper just given, 6½ parts of zinc. The genuine *tutenag* is however now regarded as zinc. The *paksong* of the East Indies is also a nickeliferous alloy. In commerce the metal is generally received in the form of grains or granulations. Various methods of obtaining the metal free from its associates are practised with the speiss and with the minerals. These, purely chemical in their nature, are described in the works on chemistry and metallurgy.—Nickel combines with oxygen to form a protoxide and a peroxide. The former is a powerful base, and its salts assume green colors complementary to those of the corresponding salts of cobalt.

NIOOBAR ISLANDS, a cluster of islands in the bay of Bengal, lying S. of the Andamans, between lat. 6° 45' and 9° 15' N., and long. 92° 45' and 94° E.; pop. about 8,000. They consist of 9 considerable islands and several smaller ones. The names of the principal are:

Great and Little Nicobar, Katchall, Noncowry, Camorta, Trinkut, Terressa, Bompooka, Tillanchong, Chowry, Batti-Malve, and Car-Nicobar. Great Nicobar is about 80 m. long and 12 m. broad, and Little Nicobar or Sambelong 14 m. long and 12 m. broad; they are the largest islands of the group, and are separated by a channel 6 m. wide. The surface of all the islands is generally hilly and well wooded. The soil is fertile, and capable of producing all the fruits and vegetables of tropical regions. Ambergris and edible birds' nests abound, and are the chief articles of exportation. The inhabitants, who resemble the Malays, are a lazy, cowardly, and perfidious race, and have frequently murdered the crews of ships which have touched on their coasts. The Danes have attempted to form settlements in one of the Nicobars, but were compelled to withdraw by the insalubrity of the climate, and in 1848 abandoned their claim to sovereignty over them. The British flag was then hoisted by the native chiefs of Car-Nicobar, but the East Indian government refused in any manner to recognize their proceedings.

NICODEMUS, a Pharisee and member of the sanhedrim, who, impressed by the miracles performed by Jesus, came to him by night, and held with him the discourse related in the third chapter of John. Subsequently he defended Jesus at a meeting of the sanhedrim, on the ground that no man could be judged until heard in his own defence (John vii. 50), and also assisted Joseph of Arimathea in laying out the dead body of the Saviour. Tradition states that afterward Nicodemus became openly a Christian, was baptized by Peter, and in consequence was deprived of his office and driven from Jerusalem; and that he took refuge until his death in the country house of his cousin Gamaliel. An apocryphal gospel is attributed to him.

NICOLA DI PISA. See PISANO.

NICOLAI, CHRISTOPH FRIEDRICH, a German author and publisher, born in Berlin, March 18, 1738, died Jan. 8, 1811. His father was a bookseller, and at the age of 16 he was sent to Frankfurt-on-the-Oder to learn the same occupation. During his apprenticeship he devoted his leisure to study. He returned to Berlin in 1752, and in 1755 published a volume of "Letters" discussing the merits of the two literary sects then agitating Germany. This work gained him the intimacy of Lessing and Moses Mendelssohn, with whom he commenced in 1757 the *Bibliothek der schönen Wissenschaften*, one of the first literary periodicals in the German language. It was continued till 1805, under the name of the *Neue Bibliothek*. In conjunction with Lessing he established in 1759 the *Briefe, die neueste Deutsche Literatur betreffend*, which exerted a powerful and wholesome influence on the development of German literature; and in 1765 he projected the *Allgemeine Deutsche Bibliothek*, which he edited until it reached its 107th volume. In

the latter part of his life Nicolai was, in consequence of illness and depression of spirits, subjected to a singular series of spectral illusions. He was for a considerable period haunted by phantoms which filled the apartment in which he was, presenting crowds of persons who moved and acted before him, and even spoke to him. After some time, and by the use of medicine, these apparitions were at length dispelled. Nicolai had observed them calmly and carefully, and reported to the philosophical society of Berlin a full account of the matter. His principal works are: *Charakteristische Anekdoten von Friedrich II.* (6 vols., Berlin, 1788-'92); *Leben und Meinungen des Magisters Sebaldus Nothanker* (4th ed., Berlin, 1799); and *Beschreibung einer Reise durch Deutschland und die Schweiz* (3d ed., 12 vols., Berlin, 1788-'96). *Nicolai's Leben und sonderbare Meinungen*, by Fichte, was edited by A. W. von Schlegel (Tübingen, 1801); and his biography and literary remains, by Göcking, were published at Berlin in 1820.

NICOLAITANS, a heretical sect, alluded to in Rev. ii. 6, 15, and supposed to have received their name from Nicolas of Antioch, one of the 7 deacons who is said to have fallen into practices opposed to the gospel and to the instructions of the apostles. According to Irenæus, who is the first Christian writer that mentions them, they held fornication and the eating of meats which had been offered to idols to be not sinful. St. Epiphanius relates that Nicolas had a beautiful wife whom he abandoned for a life of celibacy, but afterward, unable to keep his resolution, returned to her, and justified his conduct by licentious principles, which became the basis of the Nicolaitan sect. Eusebius says that they soon became extinct, but according to Tertullian they continued to exist under another name, and their heresies passed into the sect of the Cainites. It is suggested by Mosheim that the church fathers confounded them with the Gnostics, and by Neander that the name is employed in the Apocalypse in a purely symbolical sense, and signifies seducers of the people.

NICOLAS, SIR NICHOLAS HARRIS, an English antiquary and historian, born at East Looe, in Cornwall, March 10, 1799, died near Boulogne, Aug. 8, 1848. He entered the navy as midshipman in 1808, and was promoted to the rank of lieutenant in 1815. On the conclusion of the war he left the service, and, applying himself to the study of law, was called to the bar in 1825; but the greater part of his time was devoted to antiquarian and historical literature. He was chosen a member of the council of the society of antiquaries, but his imprudence and fiery temper caused him to be expelled after he had appeared once at their meeting; and he thereupon began a series of attacks on the society, which for a time occupied a very prominent place in periodical and pamphlet literature. In 1826 he became joint editor of the "Retrospective Review." He

was an indefatigable and judicious investigator, and nearly all his works possess great historical value. The most important of them are: "Life of Secretary Davison" (1823); *Notitia Historica* (1824), which was remodelled, under the title of "Chronology of History" (1835), for Lardner's "Cabinet Cyclopædia;" "Synopsis of the Peerage of England" (1825); *Testamenta Vetusta* (1826); "History of the Battle of Agincourt" (1827); "Controversy between Sir Richard Scrope and Sir Robert Grosvenor" (2 vols., 1832, unfinished); "History of the Orders of Knighthood of the British Empire" (4 vols. 4to., 1841-'2); "Observations on the Institution of the Order of the Garter," in vol. xxxi. of *Archæologia*; and "History of the Royal Navy" (2 vols. 8vo., 1847, unfinished). He prepared for Pickering's Aldine edition of the British poets the lives of Chaucer, Surrey, Wyatt, Collins, Cowper, Thomson, Burns, and Henry Kirke White, and edited the poems of Davison, the "Literary Remains of Lady Jane Grey," the "Siege of Carlarverock," the "Privy Purse Expenses of Henry VIII.," a "Chronicle of London from 1089 to 1483," "Memoirs of Lady Fanshawe, written by Herself," &c. His publication of the "Letters and Despatches of Admiral Lord Viscount Nelson" (7 vols. 8vo., 1844-'6) threw light upon points of Nelson's career which had been previously greatly misunderstood. At the time of his death he was engaged in editing the papers of Sir Hudson Lowe. He was created knight of the Hanoverian Guelphic order in 1831, chancellor of the Ionian order of St. Michael and St. George in 1832, and grand cross of the same order in 1840.

NICOLE, PIERRE, a French moralist and theologian, born in Chartres in 1625, died in 1695. He was graduated at the university of Paris in 1644, and for several years held a professorship in the Port Royal community, to which he was introduced by two of his aunts, who were members of the sisterhood. He was one of the authors of their school books, and assisted in their controversy with the Jesuits. According to the abbé Goujet, he had a share, either by advice or correction, in several of Pascal's "Provincial Letters," of which he made an elegant Latin translation under the assumed name of William Mendrock (Cologne, 1658). He was the principal author of the great work *Perpétuité de la foi de l'église Catholique touchant l'eucharistie*, published under the name of Arnauld. He shared in the persecutions which befell the Port Royalists; being obliged to leave Paris in 1677, he concealed himself in the neighborhood of Chartres and Beauvais, and in 1679 went to Brussels and thence to Liège. By the intervention of M. de Harlay, archbishop of Paris, he was at last allowed to return to France, where he again became involved in religious controversies, siding with his old adversaries the Jesuits against the Calvinists, with Bossuet against Fénelon, and with Mabillon against the abbé de Rancé. His fame

rests upon his *Essais de morale et instructions théologiques*, the publication of which, commencing in 1871, continued for several years, and extended to 25 vols. 12mo. Nicole's life was written by Goujet (12mo., 1782), and an admirable sketch of him may be found in Ste. Beuve's *Port-Royal*. Cerveau published the *Esprit de Nicole* (12mo., Paris, 1765), and Mer-san collected his *Pensées* (18mo., Paris, 1816).

NICOLET, a central co. of Canada East, on the right bank of the river St. Lawrence, and drained by the Nicolet and Becancour rivers; area, 487 sq. m.; pop. in 1851, 19,657. The capital, Nicolet, 81 m. N. N. E. from Montreal, has a Roman Catholic college with about 180 pupils.

NICOLL, ROBERT, a Scottish poet, born in Tullybeltane, Perthshire, Jan. 7, 1814, died near Edinburgh, Dec. 9, 1837. He received no education beyond reading and writing, and his earliest occupation was that of a herd boy. Afterward he was apprenticed to a grocer in Perth, and when he had served his time there opened a circulating library in Dundee. In 1835 he published a small volume of poems, which passed through 8 editions. In 1836 he undertook the editorship of the "Leeds Times," a liberal political journal, which he conducted with energy and success until near his death.

NICOLLET a S. E. co. of Minnesota, bounded E. by the Minnesota river, which also intersects it from the S. E. to the N. W.; area estimated at 650 sq. m.; pop. in 1860, 3,774. Its surface is level, and contains several lakes, of which Swan lake is the largest. Capital, St. Peter.

NICOLLET, J. N., a French astronomer and geological explorer, born in Savoy about 1795, died in Washington, D. C., Sept. 11, 1848. He was early distinguished for his attainments in astronomy and geography, and was known as the pupil and friend of Laplace, who makes frequent mention of him in his *Mécanique céleste*. He came to the United States about 1833, for the purpose of making a scientific tour, and extending the knowledge of the physical geography of North America. After exploring the southern states, he was attracted to the great basin embraced by the sources of the Red, Arkansas, and Missouri rivers, the scientific exploration of which he entered upon forthwith. In 1836 he had extended his observations even to the sources of the Mississippi. By astronomical and barometrical observations he determined the geographical position and elevation of many important points. He collected many interesting details respecting the history and dialects of the Indian nations, and of the productions and natural history of the country. Returning to the east, he was engaged by the war department, and instructed by Mr. Poinsett to revisit the far West and prepare a general report and map for the government. Fremont accompanied him as his assistant. In 1841 Nicollet presented to the association of American geologists at Phil-

adelphia an interesting communication upon the geology of the upper Mississippi region and of the cretaceous formation of the upper Missouri. In 1843, at the meeting of the association at Albany, he presented further particulars respecting the cretaceous formation, and exhibited the beautiful map of the country which he had completed for the government, and which was published by order of congress. The completion of his report was arrested by his last illness, brought on by years of exposure.

NICOMEDES I., king of Bithynia, died about 250 B. C. He succeeded his father Zipoetes in 278 B. C., and one of his first acts was to assassinate two of his younger brothers. Another brother, Zipoetes, who rebelled and took possession of the maritime districts of Bithynia, he defeated with the assistance of the Gauls, and also put to death. The remainder of his reign was devoted to useful and peaceful enterprises. He was the first ruler of the Thracian dynasty who took the title of king. He fixed his residence near the ruined Greek city of Astacus, where he built a new capital and called it Nicomedia.—NICOMEDES II., surnamed EPIPHANES, king of Bithynia from 149 to 91 B. C., and 4th in descent from the preceding. He was educated at Rome, where he found such favor with the senate that his father Prusias II., dreading his ambition, sent orders to have him assassinated. Nicomedes, discovering the plot, entered Bithynia in arms, and being supported by the inhabitants dethroned his father and put him to death. He made an alliance first with the Romans, whom he assisted in their war with Aristonicus (181), and afterward with Mithridates, and having seized Paphlagonia, placed it under the government of one of his sons. Foiled by Mithridates in an attempt upon the Cappadocian throne, to secure which he had married Laodice, the widow of Ariarathes VI., he was soon afterward deprived of Paphlagonia also by the Romans, and is said to have died of disappointment.—NICOMEDES III., surnamed PHILOPATOR, son and successor of the preceding, and the last king of Bithynia, died in 75 or the early part of 74 B. C. On the death of his father, Mithridates incited another son, Socrates, to claim the crown, and Nicomedes was driven from the kingdom. Restored by the Romans the next year, he was persuaded by his allies to make war upon Mithridates, who deposed him a second time (86) and it was not until the conclusion of the first Mithridatic war (84), which broke out in consequence of this action, that he was restored to his throne. On his death, having no children, he bequeathed his kingdom to the Romans.

NICOMEDIA, the capital of ancient Bithynia, situated on the Astacene gulf, at the E. extremity of the Propontis. It was built in 264 B. C. by Nicomedes I., and for 6 centuries prospered, being often, under the Roman empire, the residence of the emperors while engaged in their eastern wars. It was adorned with many

magnificent buildings, the ruins of which still exist, but is especially celebrated as having been the place where the historian Arrian was born, where Hannibal died, and Diocletian abdicated. The modern name is Ismeed, and the place is still of some little importance.

NICOPOLE, or NICOPOLE, a city of European Turkey, in Bulgaria, on the right bank of the Danube, 80 m. S. W. from Bucharest, and 280 m. N. W. from Constantinople; pop. about 10,000. It consists of two parts: the fortified or Turkish town, which is perched on a line of limestone cliffs, overhanging the Danube; and an open quarter on the declivity of an adjoining height, inhabited by Bulgarians, Wallachians, and Jews. It was founded by Trajan about A. D. 106, and gives title to a Greek archbishop and a Catholic bishop. The sultan Bajazet I. defeated King Sigismund of Hungary under the walls of this city in 1396.

NICOPOLE, a city of ancient Greece, in Epirus, on the Ambracian gulf, built by Augustus, in 81 B. C., to commemorate his victory over Antony at Actium. It was peopled from the Epirotic towns, invested with the privileges of a Roman colony, and raised to the dignity of an amphictyonic city. The conqueror erected a temple to Neptune and Mars, and instituted a quinquennial festival styled *Actia*. Under his successors this city became the capital of Epirus, but in the middle ages it sank into obscurity and disappeared.

NICOSIA, LÉUCOSIA, or LÉFKOSIA, a town of Asiatic Turkey, capital of the island of Cyprus, situated in the N. part of the island, 9 m. from the sea; pop. about 18,000, two thirds of whom are Turks. It is about 8 miles in circuit, and surrounded by strong walls with 8 gates, but its fortifications are all commanded by neighboring heights. With the exception of the Greek quarter, the town is generally ill built with narrow unpaved streets and hut-like houses. There are some imposing buildings however, among which are the mosque of St. Sophia, formerly a Christian church, the church of St. Catharine, the Armenian church, the church of St. Nicholas, now used as a grain depot, the seraglio, or governor's palace, erected as a royal residence while the island was held by the Christians, and the palace of the Greek archbishop. There are manufactures of Turkey leather, carpets, and silk, and British calicoes are printed for exportation. The Cyprus wines are produced on the neighboring hills.—Nicosia in the time of Constantine the Great was 9 m. in circuit, and before Cyprus came into the possession of Venice had 800 churches. It was taken from the Venetians by the Turks in 1570, when 20,000 of its inhabitants perished.

NICOT, JEAN, a French diplomatist, born in 1580, died in Paris in 1600. Being sent by Francis II. as ambassador to the court of Portugal, he there procured some seeds of a tobacco plant from a Flemish merchant, who had obtained them from Florida. These he brought

into France, and in honor of him the botanical name *Nicotiana* was given to tobacco.

NICOTIA, or NICOTINA, a volatile alkaloid, the active principle in tobacco, obtained by distillation of the infusion of the plant, an acid being placed in the receiver to fix the alkaloid. By the use of a stronger alkali it is afterward liberated and obtained in the form of a clear oily fluid of specific gravity 1.048. It possesses an exceedingly acrid burning taste, even when largely diluted, and an odor like that of tobacco, which becomes very strong when ammonia is present. Its vapor is exceedingly powerful and irritant to the nostrils, that arising from a single drop being sufficient to render the whole atmosphere of a room insupportable. Nicotia decomposes at 482°, and also by exposure to the air. It has a strong alkaline reaction, and forms crystallizable salts with the acids. It is one of the most virulent poisons known, a drop of the concentrated solution being sufficient to kill a dog, and its vapor destroying birds. Tannin combines with it to form a compound of little solubility, and it may therefore serve as an antidote to the poison. Nicotia protects the animal tissues from decomposition; and Orfila has found it several months after death in bodies of animals destroyed by it. A translation of an interesting memoir upon its properties by Orfila may be found in the "New York Journal of Medicine," N. S., vol. ix. pp. 112, 219, and 369. The proportion of the alkaloid obtained by this chemist from Havana tobacco was 2 per cent., from that of Maryland 2.3, and from that of Virginia 6.9.

NICOYA, GULF OF, a bay of Costa Rica on the Pacific ocean. The opening from the sea, between Cape Blanco on the W. and Point Herradura on the E., is 30 m. wide; and the gulf extends northward about 56 m., forming on the W. a small peninsula of the same name. It contains numerous islands, of which the principal are St. Lucar, Chira, Alcatraz, Venado, and Bejuco. Costa Rica has 3 ports on this bay, viz., Herradura, Caldera, and Punta Arenas, of which the last named is the only one now in use. The W. shore of the gulf is almost uninhabited, and both shores are low and insalubrious. A number of considerable streams fall into this gulf, of which the Tempisque and Rio Grande are the principal.

NIEBUHR, BARTHOLOMÆUS, a German historian, son of Karsten Niebuhr, born in Copenhagen, Aug. 27, 1776, died in Bonn, Jan. 2, 1831. He was two years old when his father removed to Meldorf in Holstein, where he passed his boyhood till 1792, living in retirement, adopting studious habits, and having few playmates or amusements. He learned in the nursery both the German and Danish languages; was instructed by his father in geography, history, and the English and Latin languages; derived advantage from the conversation and library of Bojes, *landvoegt* of the district; was remarkable for his capacity and proficiency, and on entering the gymnasium of Meldorf in 1789 was advanced

at once to the first class. He was private pupil of the head master, Dr. Jäger, was for 3 months in a commercial institute at Hamburg in 1792, and in 1794 was sent to the university of Kiel, where he remained two years, and became intimately acquainted with Mme. Hensler, whose sister Amalia Behrens was his first wife, with the counts Stolberg, and with Voss, Jacobi, and Schlosser. In 1796 he became private secretary to Schimmelmänn, the Danish minister of finance, was soon after appointed secretary to the royal library by Count Bernstorff, and in 1798 sailed to England, and resided chiefly in London and Edinburgh for more than a year. Having received two small appointments from the government at Copenhagen, he married, and resided in that capital till 1806, directing his studies chiefly toward classical antiquity, and establishing his reputation both as a scholar and an administrative officer. In 1806 he removed to Berlin, having received from the Prussian government an appointment as joint director of the bank, but was soon obliged to flee with the other officials after the battle of Jena. He passed through Dantzic, Königsberg, and Memel, was intrusted by Hardenberg with the financial department of the commissariat, and accompanied the army till the battle of Friedland. After the dismissal of Hardenberg (1807) he was appointed on the commission to conduct the government provisionally, and suggested fiscal reforms which were accepted by Stein after the formation of a new administration. He resided one year in Amsterdam, making unsuccessful efforts to negotiate a loan, and on his return to Berlin in 1809 was nominated privy councillor, and was made the head of the department for the management of the national debt and the supervision of the banks. The opposition made by the ministry to his financial plans caused him to demand his dismissal, and both Hardenberg and Stein attributed his conduct to an undue waywardness and impatience of disposition. His own letters prove that while the important offices to which he had been raised had given him an extravagant estimate of his financial abilities, he was nevertheless chiefly desirous to return to the literary studies from which he had been withheld by public duties. Appointed historiographer to the king, he delivered lectures on ancient Roman history in the university of Berlin in 1810 and 1811, which were immediately published, and contained the germs of his later doctrines. He was also associated with Spalding, Buttmann, Ancillon, Schleiermacher, Savigny, and a few others, in a philological society. His studies and lectures were interrupted by the events of the war of liberation in 1813-'14, by writing several political tracts, and by the subsequent illness and death of his wife; and in 1816 he sought change of scene, and went as Prussian ambassador to the court of Rome. On his way he discovered at Verona the palimpsest MS. of the "Institutes" of Gaius. In Rome he was
